ON THE CHOICE OF ELECTRIC BATTERIES.

By G. V. POORE, M.D., F.R.C.P., &c.,
Physician to University College Hospital.

The question, "What kind of battery do you advise?" is so frequently put to me by medical friends that I feel prompted to say a few words on the principles which should guide us in the choice of batteries. When a practitioner buys an electric battery, he wants, above all things, a reliable instrument, an instrument which will work effectually, even though it may have been lying by, disused, for months. To attain this end, the battery must be of the simplest possible construction, and must be furnished with elements which are constant in action, and not liable to deteriorate quickly by evaporation.

I do not advise the combination of Galvanic and Faradic batteries in the same box, and mainly for this reason, that the combination adds to the complexity of construction; that the liability to get out of order is increased, and that if one part needs repairs the owner is obliged to send the entire apparatus to the instrument maker. The advantages of having the two instruments combined are not materially greater than having them side by side, and for purposes of transport the combined instrument offers few real advantages.

First, as to the *galvanic battery*. The best elements are the Leclanché elements, or one of the modifications of them which are now made. The elements should be small, and the case which contains them should be strong and light, and furnished with a strong useful handle, such as can be *comfortably* held in the hand. This last desideratum is not possessed by any battery with which I am acquainted.

It is not necessary to have more than 20 or at most 30 elements in the same box. For myself I now always buy twenty-cell batteries. These are sufficient for the great majority of cases, and, if more power is needed, it is easy to connect two or three batteries together.

Avoid accessories in combination with the battery. The current reverser and galvanometer should be purchased as separate apparatus, and placed in circuit when required. The reason for this is obvious. The risk of failure with batteries is very largely in proportion to the number of *junctions* which occur in the circuit. In the ordinary battery, with the ordinary accessories, there are four junctions for the reverser and two junctions for the galvanometer, and if these apparatus be permanently in circuit they afford at least six serious obstacles to the passage of the current, and it need not be said that delicate apparatus made with metal easily corrodes and spoils when exposed to the fumes of a battery, or, indeed, to the gas-laden atmosphere of London or other large towns. I have long regarded the galvanometers which are usually sold in combination with batteries as *worse*

than useless. For graduating the strength of the current two methods are in common use, viz., (*a*) placing resistance in the circuit by means of a rheostat; (*b*) varying the number of cells in circuit. Now a good rheostat is an expensive piece of apparatus, and costs far more than the battery, and although for physiological purposes, when great exactness is absolutely necessary, a rheostat may be advisable, it is neither necessary nor advisable for ordinary clinical purposes. All the cheap rheostats which I have tried are very nearly worthless. A cheap and reliable rheostat is a great desideratum, and would tend to simplify the construction of batteries by making two points of connection alone necessary for even the biggest batteries. The number of cells in circuit may be varied in many ways. The common dial collector is, perhaps, the commonest method. A dial collector is most convenient and handy when it is new, but when it gets dirty or oxidised, when the spring of the revolving arm gets loose and loses its tension, and when the connections with the cells begin to oxidise or get loose, it become a vexation rather than a comfort. A dial collector increases the number of junctions in the circuit, a thing to be avoided where possible. Thus for a battery of 30 elements, a dial with 30 metal points is necessary. Each cell has to be connected with the under surface of the metal point of the dial (one junction). The arm of the dial has to be brought into contact with the upper surface of the metal point in connection with the end cell of the number used (two junctions). This junction is a mere contact junction, and a very small amount of grease or dirt or rust increases the resistance enormously. The central point of the revolving arm of the dial forms a junction with its socket (three junctions), and this, again, is a junction of an imperfect kind, very liable to get loose or otherwise deranged. The central socket has to be connected with one of the terminal poles of the battery (four junctions). Of these four junctions, all sources of inefficiency, three are unnecessary, and if these three can be dispensed with, the permanent utility of the battery will be increased.

There is another disadvantage which, in my opinion, more than counterbalances the convenience of the ordinary dial collector, and it is this: that in using the battery the first cells in the series are always in circuit, and necessarily lose their efficiency with a rapidity proportioned to the amount of use to which they are subjected. If, out of a battery of 30 cells, 15 is the average number used, then, with the ordinary dial collector, the first 15 are the ones upon which the work falls, and there is no possibility of using the whole or any part of the last 15 in the series, unless the first 15 be employed as well.

It obviously favours the working durability of a battery, if we are able to throw any individual cell or group of cells, at pleasure, into circuit. If any one cell is always of necessity in circuit, then if that one cell becomes inefficient or its connections damaged, the efficiency of the whole battery is destroyed, because no current will pass through the damaged cell.

Faulty junctions and connections are the great causes of failure in batteries, and these causes of failure exist equally in the conducting wires and rheophores. The ordinary conductors made of plaited metal thread, covered with wool or silk, are abominations not to be tolerated. They offer great resistance to the passage of the current even when new, and when they become wet the wire oxidises and breaks. These conductors are fastened to the battery at one end, and to the rheophore at the other by means of flat metal hooks or plugs, and the junction between the conductor and the hook or plug is, as a rule, flimsy and loose.

Now, if we consider the passage of a current in an ordinary battery, provided with the ordinary accessories and conductors, we shall find that the number of connections is very large indeed. First, there is the connection of the carbon plate of the element to the conducting wire (1); the attachment of the wire to the current reverser (2); two contact junctions in the reverser (3, 4); the junction of the reverser with the continuation of the conducting wire (5); two attachments to the galvanometer (6, 7); the attachment to the stud of the dial collector (8); the contact junction between the upper side of the stud with the revolving spring arm of the dial (9); the junction at the central end of the revolving arm of the dial (10); the junction between the socket of the dial and the positive pole of the battery (11), which may take the form of a socket or screw; the junction between the positive pole of the battery and the plug or hook of the conductor (12); the junction between the hook or plug of the conductor and the conducting wire (13); the junction between the conducting wire and the plug or hook of the rheophore (14); the junction between the plug or hook and the rheophore itself (15); the junction between the rheophore and its sponge or carbon (16); the junction between the sponge or carbon of the positive rheophore and the patient (17); the junction between the patient and the negative sponge or carbon (18); the junction between negative sponge or carbon and rheophore (19); between rheophore and hook or plug of conductor (20); between hook or plug and the conducting wire (21); between conducting wire and hook or plug (22); between hook or plug and the screw or socket of the battery (23); between screw or socket and the conducting wire in the battery (24); and between conducting wire and zinc plate (25). If we leave out of consideration the two contact junctions with the patient, there are 23 junctions *inseparable* from the ordinary form of battery, even when one element alone is used, and to this must be added two junctions for every additional element in circuit, and two dial-collector junctions for every few elements (three, four or five, as the case may be). A fault occurring at any one of these 23 junctions (and it is, as has already been said, at the junctions that faults are most liable to occur) may render the battery useless, or may so increase the resistance in the circuit, that no appreciable current can pass through it. It is not to be wondered at that the majority of batteries are vexatiously unreliable.

How can we reduce the number of junctions? If the reverser and galvanometer be omitted from the battery, the number will be reduced by 6, leaving 17.

I have long since abandoned the dial or any other form of collector as being, on the whole, more bother than it is worth, and I am now contented to have the elements connected with screw terminals in the manner to be hereafter described. In this way three more junctions are abolished, leaving 14. Lastly, if telegraph wire (copper wire covered with gutta percha) be used instead of the ordinary conductors, then the bright end of the wire may be united directly with the battery and rheophore, and thus four more junctions in the circuit are avoided, thus reducing the number to 10, in place of 23.

Telegraph wire (costing 1*d.* or 1½*d.* per yard) is infinitely preferable to the ordinary conductor. It offers far less resistance to the current; is not injured by damp; if the end breaks off, it is easy to lay bare a fresh piece and make a new connection; the cost is not more than one-tenth of the price charged by instrument makers for "conductors," and the necessity for connecting hooks or plugs is dispensed with. Telegraph wire allows of great latitude in making connections with rheophores. When the copper is laid bare, it may be twisted round anything, and rheophores of various kinds may be extemporised of catheters, spoons, probes, &c., as occasion may require. The only form of con-

nection which is permissible in a battery is the screw terminal, by means of which the end of the conducting wire is tightly clamped between the two sections of a screw. The two faces of the screw, which are in apposition, keep clean; and if the wire be bright when it is inserted in the clamp, the connection is as perfect as any temporary connection can be. The plug-and-socket junction, on the other hand, is thoroughly bad.

I have said that, if the elements be connected with screw-terminals round the rim of the battery, dial collectors may be dispensed with, and thus a saving of expense is effected, and the risks of failure lessened.

In a battery of twenty cells, I have nine screw-terminals. The first five cells are each of them connected with a screw-terminal, as well as the tenth, fifteenth, and twentieth; and the terminals may be thus marked: "+1, 2, 3, 4, 5, 10, 15, 20." It will be found in practice that the conducting wire is easily shifted with one hand from one screw to another, and that this arrangement, infinitely simpler and safer than a dial, is almost as convenient. It allows of very complete graduation of the current, as it is evident that any number of cells from 1 to 20 may be included in the circuit. Thus, if six cells be needed, all that is necessary is to connect with 4 and 10. If eleven cells be needed, connect with 4 and 15. If nineteen be needed, connect with 1 and 20, and so on. It allows also of any group of cells being used. The last five, or the middle groups, may be employed as readily as the first; and since the finely graduated group is needed for delicate diagnosis, it is well to avoid using it for mere therapeutic purposes.

With a battery arranged in this way, it must be remembered that when the connections are made the lower of the two numbers is always *positive* and the higher *negative*.

If a battery is to work well, it is necessary that the permanent junctions, in the battery itself, should be very well made. The soldering must be firm, and all the connecting wires and junctions must be very carefully and thoroughly coated with insulating material. I have seen batteries sent out by first-rate firms of instrument makers in which the soldered connections were bright and bare and exposed to the fumes and moisture of the battery. Such ignorant and careless workmanship as this renders the battery quite unreliable, although it may prove to be a sort of annuity to the instrument maker who repairs it.

It is always most necessary when purchasing a battery to look to see that the connections between the individual cells and between the cells and screw-terminals are properly made and thoroughly insulated and protected. In a battery there are two kinds of workmanship required—the proper setting of the galvanic elements, and the making of the accessories—and it often happens that the skill expended on these two is very unequal. I have seen batteries in which the accessories (collector, reverser, &c.) have reached the perfection of workmanship, but in which what I may call the electrical work was so execrable that no current worth speaking of could be generated. On the other hand, I have seen the electrical work admirable, while the accessories have been so vile that not even the strongest currents could force a passage through them.

If the electrical elements and the accessories be kept separate, as they should be, each may be purchased of the manufacturer who shows the greatest care and skill.

As regards rheophores, I think that, on the whole, moist sponges are the best, and the best pattern of sponge-holder is that designed by Kidder, of New York, in which the sponge is securely fastened.

I may sum up what I have said, by giving the words in which I am accustomed to order a battery from the manufacturer, viz.: "*A twenty-cell medical Leclanché battery, without accessories, with nine screw-terminals, with twenty yards of telegraph wire and two Kidder's rheophores.*"

For nineteen out of twenty cases a twenty-cell battery is big enough, and if greater power is needed, it is easy to join two batteries together. For patients the above form of battery is admirable from its simplicity. It is obvious that any form of accessories may be used with these batteries, if it be desired, but the accessories and the battery should be quite independent of each other.

With regard to *induction coils*, it is not necessary to say much. I am not so wedded to the Leclanché element for induction coils, although it answers very well. The bichromate element is a very good one for induction batteries, and excellent induction batteries are made with the bichromate elements.

All that I have said with regard to junctions, insulators, conductors, and rheophores, applies to induction batteries equally with galvanic batteries.

An induction battery to be of any use, must allow of perfect graduation of the current. The most perfect way of doing this, is the old one of allowing one coil to slide over the other. Attempts have been made to graduate the current of an induction battery by means of a cheap rheostat, but I cannot recommend induction batteries of this pattern. The graduation by allowing one coil to slide over the other is simple and perfect, and allows of exact record. An induction battery to be of any use for diagnostic purposes, must be able to furnish a current of an intensity from *nil* upwards.

LUPUS VULGARIS—ITS TREATMENT BY THE LOCAL APPLICATION OF SULPHUROUS ACID.

By HERBERT COLLIER, M.D. Brux., L.R.C.P. Lond. M.R.C.S. Eng.

Once again has the subject of lupus been brought prominently before the profession by a paper recently read at the Medical Society by Mr. Jonathan Hutchinson. The author does not consider that the term "lupus" should be employed in its present restricted sense, but that it ought to have a wider signification, and be made to include a whole group of diseases possessing natural and close affinities.

Mr. Hutchinson also contends that the definition of this term should be a clinical one, and supports this view with considerable power, and with his rich store of practical knowledge. Yet from a purely clinical standing-point how difficult is it to assume that so many different types, presenting such diverse characteristics in their clinical history, should possess a common ætiology, and differ from each other only on account of the individual diathesis of the subject attacked.

Thus from a purely clinical study of these diseases, how impossible would it be to prove, or fairly contend, that the rapacious and destructive lupus exedens, which in the course of a few weeks may destroy by its ravages the greater part of the nose, lips, cheeks, and forehead, and continue this career of spoliation, unchecked by the most powerful chemical applications the most heroic surgical interference, the most subtle therapeutics, and fire itself in its many and different modifications, owns the same ætiology with the insidious lupus erythematosus, which almost imperceptibly attacks its victims, and only declares its wolf-like nature when its pernicious effects are but too complete.

From a purely clinical study of these two types, I say would it not be most difficult to assume that they differ only on account of the peculiarity of the soil on which they are placed?

Is it not by a pathological light, rather than by a clinical investigation that we have ascertained the links of connection between the several types of lupus?

In the present immature state of our knowledge of the true nature of this disease, would it not be better, then, to accept a pathological definition, perhaps the following:—a new growth of the skin or mucous membranes, accompanied by active congestion, and followed by exfoliation, degeneration, and interstitial absorption or ulceration, and terminating in scar formations. Now, although for the sake of pathological accuracy this definition is made to include "mucous membranes," it is most important to bear in mind that these tissues are never primarily affected, but always become implicated by extension.

I cannot help laying great stress upon the significance of this latter point, as of much diagnostic value in discriminating between true lupus, and certain of its so-called allies, more especially those associated with tertiary syphilis; and, as a most interesting illustration of this point, I may be permitted to cite the following case.

Margaret A., aged 25, was brought under my notice in March last by a medical friend, who supposed her to be suffering from lupus vulgaris. His object in calling my attention to her case was to kindly afford me an opportunity of testing the value of the treatment I am about to suggest for this disease, which, in two most obstinate examples, he had seen effect rapid cures after all other recognised methods had been tried with complete failure.

In this case there had been extensive and deep ulceration of the nostrils, lips (the upper one being almost entirely destroyed), cheeks, and forehead, where the left margin of ulcerated surface was very considerably thickened, and covered with rough congested skin. In addition there were swellings over the sternal end of the right clavicle and right acromio-clavicular joint; the former about the size of half a walnut, covered with thin congested skin, had some semi-fluid contents, and the latter, about twice as large, was excavated by ulceration similar to that on the forehead. There was also a large and irregular perforation of the palate.

Her family history was good; no indication of syphilis or lupus in any other member. Her parents were in a respectable position. At the age of sixteen she paid a visit to Hull, and some weeks afterwards the sight of the right eye began to fail, apparently from the formation of a cloud over its centre; the left eye shortly afterwards became similarly affected, and for some time she was blind, although light was still perceptible. After treatment for five months, her sight began to return, first in the right eye, then in the left. She was under hospital treatment throughout.

About four years afterwards, when she was twenty, a swelling grew in the palate, burst, and ulcerated into the nose. There was no history of previous sore throat, skin eruptions, loss of hair, or tender spots upon the head or skin. Since then she had been perpetually ailing, and the ulceration had spread to the face, committing the ravages already alluded to.

Feeling confident that the case was one of syphilis, we ordered large doses of iodide of potassium, with bark and ammonia. This treatment was followed by rapid subsidence of all lupoid action, and the patient gained rapidly in health and strength. At the present time her deformities alone mark where the disease has been.

In this case, although we had a history of keratitis at the age of sixteen, four years before the disease had declared itself, we had nothing else particularly indicating the existence of syphilis but the mode of onset, the *spreading of the disease from a mucous to a cutaneous surface.*

My chief object, however, in obtruding myself upon the notice of the profession, is not to offer any special comments upon the subject of Mr. Jonathan Hutchinson's most interesting paper, but to present to the profession what I must humbly consider, at all events in my own experience, and (what is far more important) in the estimation of one decided authority, Mr. James Rouse, to be one of the most successful methods of treatment yet brought to light for lupus vulgaris—the local employment of sulphurous acid to the ulcerated surface.

To the above-named gentleman is due, I believe, the honour of first having employed this form of treatment, although as early as the autumn of 1876, I treated and cured my first case with it; but at that time I was not aware that this method had already been adopted.

Mr. Rouse informs me, that in nearly every case in which this form of treatment has been carried out carefully under his direction, some improvement has occurred, although, in not a few, the patients' premature discharge from hospital precluded the possibility of treatment being continued to a successful issue.

The experience of Mr. Rouse exactly accords with my own; for in nine cases treated by the local application of sulphurous acid, I am able to record five distinct cures, three in which great improvement was effected, but which, unfortunately, passed from my hands before a cure could be concluded, and only one in which a negative result was obtained—this last being under treatment for fourteen days.

And this form of treatment will, I am sure, be not the less acceptable, because it is free from the usual modifications of cutting, bruising, burning, &c., now so generally resorted to, and consists simply and wholly in the employment of a slightly irritating application to the ulcerated surface of the disease.

Sulphurous acid has long been recognised as a valuable disinfectant and parasiticide, and has been in frequent use for most of the local skin affections, connected with the presence of living organisms. It has also been much advocated by various authorities for such general affections as tonsillitis, malignant sore throat (scarlatinal and laryngeal), diphtheria, croup, influenza, and chronic phthisis, locally applied, and internally administered, whilst in typhus and typhoid it is in great repute abroad, its advocates claiming that by its employment in large doses, these fevers are diminished in both severity and duration.

I am not, however, aware that any very exact explanation has yet been offered of its physiological or therapeutic actions when taken by the mouth.

Recognising its powerfully destructive effects upon some forms of micro-organic life, it will not be difficult to conceive how its curative results may be produced in lupus vulgaris, if we assume that the bacillus associated with this disease, exerts some distinct influence in keeping alive the obstinate ulceration (perhaps by preventing the formation of healthy granulations), but is incapable of existence, growth, or activity in the presence of sulphurous acid. Besides this germ-destroying influence, sulphurous acid also exerts a powerfully stimulating action when applied to the surface of open wounds, and I have particularly noticed its excellent effects upon certain indolent ulcers, which have resisted the influence of many other modes of treatment, including carbolic acid. In fact, my experience of its use, in these particular cases, compels me to consider that it is preferable to the latter in most forms of simple ulceration. It is far less irri-

tating, and consequently may be employed where carbolic acid would certainly do harm. Its stimulating influence may account then, to some extent, for its beneficial effect in lupus vulgaris. In gonorrhœa its effects, as an injection, are most happy, and I shall shortly publish the notes of 120 cases of this disease treated by its local employment.

In the local employment of this remedial agent, it may be applied in the form of a lotion, or an oil, or in the gaseous state. The last-mentioned modification is most useful, when its application is required to parts distant from the respiratory organs, and can readily be obtained by burning sulphur in a jar or open-mouthed bottle, and allowing the rising fumes free contact with the surface to be treated; the frequency and duration of these fumigations will mainly depend upon the progress made during its employment, but, as a rule, two applications daily, each for about twenty minutes, will be found sufficient to produce the healing effect of the remedy.

The lotion is best obtained by the use of the pharmacopœial preparation of the acid, either alone, or diluted to relative strengths of one in two, one in three, or one in four; the last preparation is the weakest which should be employed. It is a clean and simple mode of application, and can be applied to any part of the face without causing disagreeable effects; the great objection to its use being that it has to be constantly repeated, and evaporates much more quickly than when employed in the form of an oil.

This last-named method is my favourite form of applying the remedy. It is best made by dissolving the anhydrous acid (which may be procured at all druggists in the shape of a concentrated alcoholic solution) in castor or olive oil. I may state that I consider the former to be preferred as a vehicle, as it holds the acid in more complete solution, parts with it less readily, and forms a more perfect covering to the surface of the wound. The anhydrous acid, mentioned in connection with the sulphurated oil, may also be employed proportionally diluted as a lotion.

In conclusion, I may be permitted to record the notes of those cases which I have treated most successfully by this method up to the present.

Case I.—Emily H., aged 13, was suffering from an ulcerated lupoid patch, the size of a shilling, which involved the right ala of nose and adjacent part of cheek. Nothing of interest in personal or family history. Has always been delicate. When eleven years of age, scratched herself with a thorn. This gave rise to a small sore (which has never healed), and lately has been getting larger.

Child pale and thin. Tongue coated. Breath offensive. Several enlarged, but painless glands behind the right sterno-mastoid muscle. Viscera healthy. An indolent ulcer with raised edges, and surrounded by thickened dusky-coloured congested skin, occupying the above-mentioned position. She has been treated on and off since the sore was first noticed.

She was placed upon a mixture of soda, rhubarb and diluted hydrocyanic acid, and a solution of sulphurous acid in glycerine (at first one to six and ultimately one to three) was kept constantly applied to the surface of the whole patch.

In three weeks the wound had entirely healed, the patch itself assumed an almost healthy aspect, and the enlarged glands could no longer be felt.

Case II.—H. S., aged 15, had suffered from an open sore affecting his lower lip and chin for a "long time, certainly more than two years." Does not remember when or how it first came, but it has been getting rapidly larger during the last six months. The mother says that she first noticed it a few weeks after he had scratched a pimple off his chin. It was then very small.

Father died of consumption at the age of forty-two. Mother alive, and in good health. One sister died in infancy of "diarrhœa," and one at the age of seventeen in a "rapid decline." Three younger brothers all alive and healthy. Has had scarlet fever, measles, and whooping-cough, but all very slightly. Viscera all healthy.

Occupying the chin and lower lip is a large irregular and somewhat excavated ulcer, the size of a two-shilling-piece, surrounded by congested and thickened skin. The lower edge more prominent and somewhat everted.

Cod-liver oil, steel wine, and arsenic were first administered, and although the general health improved markedly, the local disease underwent no change for the better.

Glycerine solution of sulphurous acid in equal parts was now applied, and from its first employment great benefit was derived.

In ten weeks the wound had healed, and treatment terminated.

Case III.—Miss H., aged 33, consulted me upon the subject of a small indolent ulcer, situated upon the left ala of the nose. Does not remember how it first appeared, but is quite sure that she has been troubled by it for more than three years. It has not increased in size for nearly a year. Her general health is good. The ulcer does not give rise to much pain.

Occupying the edge and outer surface of the left nostril is a lupoid patch, the size of a sixpenny-piece, presenting towards its upper aspect a smooth indolent ulcer, surrounded by thickened, congested, and shiny skin.

Sulphurous Acid, in the form of an oil, composed of ʒi. of Herring's alcoholic solution of sulphurous anhydride, with two ounces of castor oil, was applied.

In ten days the ulcer had completely healed.

Case IV.—Clara G., aged 22, came under notice on account of a large lupoid ulcer, involving the forehead, above the right eyebrow.

Three months before, a "very small knot had appeared, become painful, and burst." It increased rapidly as a "spreading ulcer," and she states that she can see it "grow larger every day." She has been always healthy up to this time.

Two uncles died "in decline." Father and mother are both alive and healthy. There were no other children.

Involving nearly the whole of the right half of the forehead, is a large oval lupoid patch with its lower edge running parallel with, and half an inch above, the right eyebrow. The patient appears to be suffering from disordered digestion, and is in a low, depressed and feeble state of health. There is slight dulness over both apices of the lungs, breathing in the right apex is jerky and distant, in the left harsh and irregular. The patient states she is losing flesh, and suffers from slight attacks of sweating every morning about five.

She was placed on a mixture of soda, aloes, and strychnine; and when digestion improved, cod-liver oil, iron, and arsenic were substituted The local disease was not treated specially, but simply dressed with dry lint. All the general symptoms improved, and the patient rapidly gained strength and weight. Still, although the local symptoms did not increase, there was no indication of improvement.

Sulphurous acid was now applied, at first with equal parts of glycerine, and subsequently in the form of the oil mentioned before.

At the end of seven weeks the patient was quite well, and expressed herself as feeling stronger than she ever remembered to have done before.

Case V.—Amelia W., aged 20, has been affected with an "eating-away ulcer" on the right cheek, for the last three years.

The disease had first appeared in the form of a small hard lump, which was slightly tender and painful, but

*

in other respects gave rise to no inconvenience. In this state she was treated by a general practitioner, who painted it with iodine, but without producing any improvement. Subsequently it burst, and she then entered Norwich Hospital as an in-patient.

The disease was first treated by the local application of an ointment, it was afterwards scraped, the patient being under the influence of an anæsthetic, but no benefit followed this, and she was discharged at the end of five months, the disease having steadily increased.

A month before her entrance into Norwich Hospital, a small pimple appeared on the forehead, above the right eyebrow; this remained stationary for a few weeks, and then broke, and a small indolent ulcer formed, but did not extend very rapidly. It was treated during her residence at Norwich Hospital, and after having been "scraped, rapidly healed." She was also taking medicine during the whole time she was in hospital.

The patient states that in respect to the disease on her cheek, she was discharged incurable. Remained under no treatment for a month, and then went to the London Hospital as an in-patient. After taking medicine for about a fortnight, the "ulcerated surface was burnt with an acid." She was discharged at the end of two months, the ulcer in the meantime having increased very much in size.

She now returned to her home at Gorleston, and placed herself under the general practitioner who first attended her. He ordered her cod-liver oil, iron, and arsenic, with iodoform locally applied. The disease, however, steadily increased; it was at this stage that she was brought under my notice.

The patient was much emaciated, with feeble pulse, coated tongue, offensive breath, and disordered digestion. Her medical adviser informed me that the disease had certainly progressed since the local employment of iodoform. There was hypo-resonance over the apices of both lungs, and the breathing was coarse and deficient. The temperature, when first seen, was 100·5°. She complained of nocturnal sweats, chills, and heats, and was said to be growing weaker every day.

Occupying the right cheek, and involving the tragus of the ear, and two inches and a half of the adjacent surface of the face, and extending from the hair above to a point three inches and a half below, was a large irregular excavated ulcer. This was limited by everted and undermined edges, and surrounded by a zone of thickened and congested skin.

The whole surface of the ear was also the seat of superficial ulceration—this latter condition had only developed since the application of the iodoform.

The patient was placed upon a mixture containing soda, aloes, nux vomica, and diluted hydrocyanic acid, and equal parts of glycerine and sulphurous acid were applied locally. At the end of a week the ulceration of the ear had healed, and the whole surface of the lupoid sore had assumed a healthier aspect, it certainly had not increased; the patient felt much better in her general health.

At the end of a fortnight, small healthy granulations sprang up all over the surface of the ulcer, which now presented a more even surface.

From this time, the patient steadily increased in health and strength, and at the end of fourteen weeks, from the first commencement of treatment (during which time iron, strychnine, and cod-liver oil had replaced the soda and aloes mixture, and the sulphurated oil had been substituted for the glycerine application), her cure was complete. This occurred last October twelve-month, and since that time she has enjoyed excellent health, and has had no return of the local disease.

SPONTANEOUS RUPTURE OF HYDROCEPHALUS.[1]

By ALAN REEVE MANBY, M.R.C.S.

On May 20th, 1873, I was summoned to a primipara, who had been in labour 24 hours, and was suffering from too much inertia to deliver the head, which I accordingly did for her, with the forceps. The child was an unusually fine male, but had a large spina bifida of all the lumbar, and one or two of the lower dorsal vertebræ, the integuments of which were so thin and transparent, that the vertebral canal was distinctly visible with its contents, some of the fibres of the cauda equina ramifying just beneath the skin. There was also a peculiar deformity of the right foot, which was flat, like a negro's, with the heel projecting nearly as far back as the toes did forward. The child was dressed with the usual abdominal bandage, the pressure of which caused suppurative inflammation, and thickening of the surface of the tumour, so that by August of the same year nothing remained but a fleshy mass, pressure on which caused no discomfort to the child. About this time, however, the mother noticed that the head was "getting bigger," and that the child "stretched itself out and turned blue, as if convulsed, when she dressed it." When I saw it on October 1st, the child being then eighteen weeks old, it was decidedly hydrocephalous, but otherwise so well that no treatment was suggested or permitted. By Christmas, the head was so large and cumbrous that, when at home in London, the mother showed it to Mr. Jonathan Hutchinson, at the London Hospital, and I lost sight of the case till the evening of January 24th, 1874, when the father came to tell me that the "head had burst, and that pints of water were squirting away," as indeed they were, for seven and three-quarter pints of slightly bloody serous fluid were collected in a pail, besides a great quantity which must have been lost on the floor, and in the mother's clothing, which were sodden, as she nursed it. The child seemed relieved by the discharge, and slept better than usual, taking and crying for the breast naturally, but it died in its mother's arms at 10·30 next morning, or seventeen hours after the oozing was detected.

The only measurement that had been taken during life was the width from ear to ear, across the crown, and which was 27 inches.

Mr. Amyot published a very similar case (*Medical Times and Gazette*, 1869), which lived 24 hours; and a case, aged ten and a half months (reported briefly in the *Medical Times and Gazette*, April 14th, 1869, p. 421), soon after this, by Dr. Frederick Brown, of Rochester, died 96½ hours after bursting, and the discharge of two quarts of coffee-coloured fluid, on which the head "fell in, looking like broken pottery."

I was only allowed to make a very incomplete inspection, and by no persuasion or bribery could I induce the parent to part with the body for a museum. The aspect of the child was typical, according to Prescott Hewett (*London Medical Gazette*, 1844, or Watson's "Practice of Physic," fourth edition, vol. i, p. 473), of intra-ventricular fluid, the facial skin being drawn upwards and outwards, arching the eyebrows, and rendering the supra-orbital ridges prominent, the pupils of the eyes turned down, leaving

[1] Read before the Norwich Medico-Chirurgical Society.

the upper part of the conjunctiva exposed. The skull presented the appearance of a large bowl, with jagged edges, the scalp having collapsed completely, an appearance Trousseau somewhat poetically describes (Trousseau, "Clinical Medicine," New Syd. Soc., vol. i, p. 474), as "like the petals of an opening flower," but which Dr. Brown, with more truth, calls "a horrible and sickening sight." It measured, without allowing for the in-squeezing of the bones, as it was held, 23 inches round the edges, and half-an-inch more a little lower down, in circumference; probably, for the age of the child, it is one of, if not, the largest on record; for a child of three years old, which Dr. Gardner, of New York (*Medical Times and Gazette*, 1861, p. 259), exhibited in 1861, as having the largest head but one, "in or out of any museum," measured but 23 inches from the tip of one ear to the other, and 37½ inches from the junction of the nasal bones to the os frontis, to the base of the occipital bone he also gives the horizontal diameter as 32 inches, but as that would imply a circumference of more than eight feet, and as, moreover, he speaks of circumference further on, we must conclude that he means horizontal circumference. The scalp was thick and elastic, covered with large veins, and seemed to be structurally natural, with the exception of a rough reddened patch, the size of a shilling, about the middle of the left half, in the centre of which was a small pin-point hole, through which the water had passed; on enlarging this, and raising the scalp, air rushed in with a whistling noise, and a little more water passed out. The brain was unrolled, and spread in a thin, coarsely reticulated layer over the inside. Ulceration and thinning of the membranes was evident beneath the red spot which had given way in the centre, as before described.

Cases of spontaneous evacuation of the hydrocephalic fluid may be found here and there in medical literature, but, excepting Dr. Brown's and Mr. Amyot's cases, none resemble mine. Mr. Greenhow, of Newcastle, published a case in 1852 (Newcastle Pathological Society, November, 1852), in which the fluid exuded through the scalp, without any definite opening, during the child's straining efforts, and cases of fatal and non-fatal rupture through the ethmoid bone and nares are mentioned by Trousseau (New Syd. Soc., vol. i, p. 477); Leonard Sedgwick (*Medical Times and Gazette*, March 15th, 1856, p. 259), and others.

A curious case, the converse of mine, was shown at the Pathological Society in 1857, by Mr. Hutchinson (Pathological Society, *Medical Times and Gazette*, March 17th, 1857), in which the head decreased, while a spina bifida in the sacral region oozed. The child ultimately died, and at the autopsy, the central canal of the spinal cord was found dilated to the size of a crow quill.

Chronic Dysentery with Pseudo-Polypi in the Large Intestines.—Dr. J. H. Musser recently showed to the Pathological Society of Philadelphia specimens illustrating this condition from two patients who had suffered from dysentery. In the *American Journal of Medical Sciences* for January, 1881, Dr. Woodward described the mode of origin and development of these polypi as dependent on (1) a granulating ulcerated surface of the intestine, (2) numerous islets of mucous membrane on this surface. "The formation of cicatricial contractions commenced in the infiltrated submucosa constricting the margin of the islets of mucous membrane, which were further transformed by hyperplastic inflammatory processes, until ultimately they acquired the form of pedunculated excrescences, and projected into the lumen of the intestine like so many little polypi," being pushed out by the contraction of the connective tissue.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CHARING CROSS HOSPITAL.

CASE OF DOUBLE POPLITEAL ANEURYSM, WITH REMARKS.

By RICHARD BARWELL, F.R.C.S.,
Senior Surgeon to Charing Cross Hospital.

William S., aged 31, a booking clerk, in the employ of the London Steam Boat Company, was admitted into Charing Cross Hospital, under my care, on November 24th, 1883, having been sent to me by Dr. Steggall, of Queen Square, who had diagnosed a popliteal aneurysm.

History.—About seven weeks ago he first noticed a small swelling in the left popliteal space, to which his attention was drawn by a sense of throbbing. This swelling pretty rapidly increased. Fifteen years ago he had a sore on the penis; as no symptoms of syphilis ever appeared, this probably was merely a chancroid. For the last few weeks he has been falling into a low depressed condition.

State on Admission.—The man is somewhat anæmic and weak. He complains of numbness and formication from a little above the knee downward, also of pretty severe pains running chiefly down the back of the leg to the inner ankle, sometimes in front. These, which are worse at night, he has called sciatica. Examination revealed in the left popliteal space a tumour of considerable size, nearly as large as a goose's egg, the long axis lying obliquely in the space. Its pulsation was evident to both sight and touch; it appeared very close to the skin, and was very characteristically expansile. Pressure on the femoral artery at the groin eliminated the pulsation, the tumour becoming quite small and flaccid. On releasing the vessel, the aneurysm at once regained its size and hardness, pulsation becoming immediately visible and sensible. There was not the slightest *bruit*, nor even the faintest murmur. A rather exaggerated pulsation existed also in the right popliteal space, but the most rigid examination could discover no tumour.

November 30th.—I ligatured the left superficial femoral artery with ox-aorta ligature. While on the table it was discovered that a tumour had during the last few days developed in the right popliteal space, of the same character as the one on the left side.

December 1st.—Patient quite comfortable this morning, no pulsation in tumour; temperature of left popliteal space was 4° higher than right, during the night. At present they are of the same temperature, *i.e.*, normal.

December 11th.—Wound quite healed, the aneurysmal tumour is smaller and quite hard; there is not the least pulsation.

December 12th.—Non-continuous digital pressure was begun to-day on the right common femoral, as it lies on the pectineus, by relays of dressers. They begin at 10 a.m. and leave off at 8 p.m. One applies the pressure on the femoral, while the other tests its efficacy by keeping his fingers on the tumour and seeing that the pulsation in it ceases.

December 13th.—Digital pressure continued, but without any material difference in the pulsations.

December 14th.—Digital pressure brought to a close, as evidently of no avail.

December 21st.—Patient went home to-day.

January 8th, 1884.—Patient returned to hospital to-day. The tumour in the right ham has increased slightly in size, and the pulsation seems closer beneath the fingers.

January 17th.—I tied the right superficial femoral artery with ox-aorta ligature. The wound was dressed antiseptically; an ox-aorta drainage tube was used.

January 19th.—Last night at 9 o'clock the patient's temperature suddenly rose to 102·2°, he complained of intense headache and great thirst; an ice bag was ordered to the head, and he was given ice to suck. This morning the temperature was down to 100°.

January 21st.—Feels much better to-day; headache gone. Complains of slight pain in wound, and some shooting pains in calf of leg. No pulsation in aneurysm. Temperature 98·4°.

January 24th.—Dressings removed to-day, they were slightly stained with discharge. The wound was healed along the upper half of incision, but pressure released a quantity of pus from the lower half; the drainage tube had become absorbed. Temperature 99·2°.

January 29th.—Wound looks healthy. Aneurysm solid and pulseless; no pain. Temperature normal.

February 4th.—Complains this morning of pain in wound, which was found to be inflamed on removing dressings. Lower end open and discharging pus, without smell. Re-dressed, much to patient's relief.

February 11th.—Wound not looking very well; was ordered to be poulticed. Temperature normal.

February 18th.—Still poulticing the wound; it looks quite healthy and clean this morning; general condition good. Aneurysm very much smaller and quite solid. Temperature normal.

February 22nd.—Poultices discontinued. Edges of wound brought together with plaster, and simple dressing applied over all.

February 27th.—Patient got up to-day for first time since operation. Complains of feeling very weak on his legs, which, with his feet, are cold.

March 6th.—Has been getting up every day since last note. Gaining strength fast; no pain anywhere; feet and legs warm, and can walk fairly well.

March 25th.—Discharged.

Remarks.—Several points are of interest in this case. The left aneurysm was, when the man presented himself at the hospital, very large, the sac being thin and lying close to the skin. Hence the special points of diagnosis were demonstrable with great clearness to the class. Absence of *bruit* is, in my experience, so very common in aneurysm that it can never be taken to negative the aneurysmal nature of any tumour, although when present, clearly and distinctly, it will assist diagnosis if the fact be recollected that certain other tumours, especially if they lie upon bone or other hard substance, may transmit a sufficiently loud, though generally a confused and more or less continuous murmur. It is, however, especially important to teach how very little reliance is to be placed on the absence of murmurs or *bruits* in the diagnosis of aneurysm.

Of far more value, as pathognomic symptoms, are the empty, flaccid condition of the aneurysm produced by occluding the artery above, especially on releasing the vessel that sudden bounds to its former size, and the instantaneous resumption of rhythmic expansile pulsation. In order to teach my class more fully to recognise this expansile sensation, I made use of a device, which was suggested to my mind by the very character of this aneurysmal pulse:—I procured two india-rubber ball syringes, each holding an ounce, and connected their nozzles by means of about two feet of tightly fitting india-rubber tubing, taking care to keep them both full. One of these the teacher places in the pupil's hand, or between the opposing fingers of both his hands. Holding the other himself, he alternately squeezes and releases it in synchronous rhythm with the pulse, causing the ball which the pupil holds to expand and relax in a manner precisely like an aneurysm. When the character of expansile pulsation has thus been learned, the teacher, ceasing that manipulation of his own syringe, takes the nozzle of the other, and impels it in alternating little jerks against the pupil's hand, thus giving him the idea of "communicated pulsation."[1]

Reverting to the patient's condition; the very thin walls of the large tumour first described representing an aneurysm devoid of any lining by clot, devoid therefore of any tendency to spontaneous cure, showed that treatment by any form of pressure would not only probably fail, but might prove dangerous by causing expansion, even perhaps rupture of the sac. Reid's method appeared to me of all forms of pressure, in this particular case, the most hazardous. I, therefore, decided to tie at once, using the ox-aorta ligature: the aneurysm rapidly solidified, and I have nothing further to say about that, the left, one.

But there are some interesting circumstances connected with the condition of things in the right popliteal space. As is well known, popliteal aneurysm is not unfrequently double. I have endeavoured elsewhere[2] to account for this peculiarity. In this case, when the man first came under notice, the right popliteal artery beat with unusual force, yet did not present any enlargement that could be verified as aneurysmal. After a week's rigid confinement to bed, this forcible pulsation had developed into a distinct aneurysm. The left femoral was tied, and then, after another fortnight's complete rest, the right aneurysm had attained a considerable size. If this case stood alone, it might be taken to show that obstruction of the one vessel, first by aneurysm then by ligature, produced over-fulness of blood in its fellow of the opposite side, and thus conduced to the formation of the second aneurysm. But we must read with this case one published by Professor Humphry. He tied a right femoral artery for popliteal aneurysm, and after a time another aneurysm in the opposite popliteal space was developed,[3] but not from any local plethora produced by obstruction of the right artery; for the man was, on account of reiterated secondary hæmorrhages, very exsanguineous, and the action of the heart was very weak. I presume, that in both these cases the original lesion of the inner and middle coats had occurred prior to surgical observation; the subsequent development of aneurysm, even under perfect rest, and in Humphry's case with severe bleedings, was a mere question of time. If this be so, the cases would militate against the value of rest-treatment, and of Valsalva's method, at all events in external aneurysms. The mode of pressure-treatment employed was experimental; had during its continuance any, even the slightest, sign of benefit appeared that treatment would have been continued. But such signs were not merely absent; I believed that the aneurysm under the use of pressure increased more rapidly, the pulsation was certainly nearer the surface. As also the man's health was a good deal affected by it, I deemed it wise to discontinue that treatment, and to substitute deligation.

[1] The expansile pulsation may be further demonstrated by placing the pupil's syringe on a table, and covering it with a thick cloth or some layers of wadding, to represent a deeply seated aneurysm.

[2] See my article on "Aneurysm" in the *International Encyclopædia of Surgery*, vol. iii, p. 380.

Medical Times and Gazette.

SATURDAY, APRIL 26, 1884.

Two papers of much laryngological interest were brought before the Clinical Society at its last meeting. Dr. de Havilland Hall described the sequel of a case of perichondritis of the larynx previously communicated to the Society, and Dr. Percy Kidd contributed a case of tubercular tumours of the larynx which were under observation for a period of nine months, during which time no disintegration of their tissue had taken place. They had attained their full size in the larynx before any symptoms of pulmonary disease could be discovered. The occurrence of such tumours is certainly to be reckoned among the rarer phenomena of laryngeal disease, and Dr. Kidd was only able to quote the experience of one other observer, to show that his own case was not absolutely unique. Several speakers, however, were in a position to prove that laryngeal inflammation, undistinguishable from the tuberculous form, might precede the development of the same disease in the lungs.

The subject of operative treatment in cases of rectal cancer was introduced in a paper by Mr. Harrison Cripps, giving details of several cases in which he had performed the operation of excision. The discussion was chiefly confined to the individual experience of operators in such cases, and the general opinion of the value of excision of the rectum as a remedial, if not absolutely curative measure, was not questioned by any of the speakers. The President, however, expressed some doubt as to whether it could be shown that life was prolonged in any cases beyond the limit which might possibly be attained without any interference; a view which was promptly combatted by Mr. Cripps in his reply. There can be no doubt that the operation has of late years gained much favour, but there can be equally little question of the fact that much yet remains to be devised in order to overcome the troublesome sequelæ of anal constriction and fæcal incontinence, which would appear to have been present after most of the operations hitherto performed. An interesting case of tubercular meningitis in an infant, by Dr. Angel Money, gave rise, owing to the lateness of the hour, to less discussion than the subject merited. We append elsewhere a list of the living specimens exhibited to the Meeting.

At the Royal Medical and Chirurgical Society two papers of great interest were read and discussed. The first was on the Cause of the Increase of Cancer in England and Wales, by Mr. Jessett. After analysing the Registrar-General's statistics and showing the increase, the various possible causes were discussed. The author thought that much good would result if the medical profession were to set their face strongly against the inter-marriage of those persons with an hereditary tendency to cancer. He did not believe in the local origin, nor in the neurotic theory of origin alone; though both these causes might prove effective in persons hereditarily predisposed. The second paper, by Mr. Macnamara, on Epiphysitis, gave rise to a spirited but one-sided discussion. The author proposed the term Epiphysitis for various diseases of bone, which he claimed to be allied by reason that they all commenced at the epiphyseal junction, viz., diffuse ostitis, osteo-myelitis, suppurative periostitis. He recorded cases giving the symptoms, pathology, and treatment, and also showed the patients. Mr. Holmes, while agreeing as to the interest and importance of the cases, differed *toto cœlo* in their interpretation; he thought it very unwise and inappropriate to group together such divers cases, and more especially to give them the term Epiphysitis, seeing that the epiphysis was in no way implicated in the disease, and had nothing whatever to do with it. Mr. Thomas Smith followed, and agreed with Mr. Holmes. Indeed, all the speakers condemned the use of the term for such cases. In his reply, Mr. Macnamara supported his own view, reiterating his chief point as contained in an abstract of his paper, which we publish elsewhere. We hope that such an expression of opinion as to the unsuitability of the term for these various forms of disease—each having an entity of its own—will induce the author to carefully re-consider his position, and lead him to adopt either a more appropriate collective term, if he thinks it desirable to group them; or to leave the subject where it was before. An adequate account of these various diseases remains to be written, as a glance at our text-books will quickly show; but it must be undertaken only by one who has a very wide field of observation, since the diseases appear to differ as greatly in respect to age as to ætiology.

Dr. Bristowe, in his paper on the use of hospitals as training schools for nurses, at the meeting of the Hospitals' Association on Wednesday last, dwelt at some length on the gradual development of the nursing system now in operation at St. Thomas's Hospital, and showed very clearly the benefits which have accrued to all concerned by its adoption. He is of opinion that the demand for skilled nurses will in future be greater than that for medical men, hence the facilities for training them must be increased, this he would accomplish by multiplying small schools throughout the country, rather than by means of large schools. Every hospital and some of the better infirmaries, should have each their own nursing school. He regards the existence of a nursing school at a medical school as a distinct advantage to all parties, and would never hesitate to give a nurse as full information on a case, as he would to a student. The nursing school ought to be under the immediate control of the committee of management of the hospital, a view that will be shared by many who have not forgotten the effects of an opposite system last year. As usual, the question of pounds, shillings and pence has to be thought of, and Dr. Bristowe pointed out some ways in which he thought that this difficulty might be met; they included voluntary support from the public, payment by the friends of those who are to be trained, and the suggestion that the probationers might live with their friends and come to the hospital every day.

The paper which followed was by Miss Lückes, matron of the London Hospital, and is marked throughout by sound common sense and a complete grasp of the subject. In the course of her remarks she gave vent to sentiments with which we find ourselves in entire accord, for instance, in speaking of the permanent staff of nurses in a hospital, she said that the fully trained workers should be allotted to, and kept in, their respective wards, without any idea of being transferred from one to another, unless under exceptional circumstances, to be approved by all concerned; it would, indeed, be well for the patients if all matrons of hospitals held the same views and acted upon them. "No one could deplore," said Miss Lückes, "more strongly than I should do any attempt to sacrifice the efficiency of the nursing of a hospital by an *undue* enlargement of its training school. Under no circumstances could it be desirable to take unlimited numbers of inexperienced women, and reduce the regular staff to an extent that would be inconvenient to the medical staff, injurious to the patients, and deteriorating to the quality of the training given." Miss Lückes has no sympathy with amateurs in the wards, all who take up nursing must be in earnest, and have the same duties, and be treated exactly alike. The training should be as far as possible thorough, so that at the completion of it a nurse should be fit to deal with a case which presented both medical and surgical features. The long hours which are so often imposed upon nurses were alluded to, and the truth and importance of the statement may be freely admitted, but the only conceivable remedy would be to enlarge the nursing staff, and that in the present embarrassed condition (financially speaking) of most of our hospitals is simply out of the question. In conclusion, Miss Lückes could see no difficulties to prevent the harmonious working of a training school for nurses and a medical school, no confusion could arise n practice, except from a failure to appreciate the elative positions of doctors and nurses.

The old-fashioned practice of giving a complete estimation of the mineral constituents of a water, which has of late fallen into disrepute, and been to a great extent superseded by the rival processes for calculating the organic matter present, more or less indirectly found an able advocate in Dr. Ashby, at the meeting of the Society of Medical Officers of Health, on Friday last. He showed that analyses of water from wells, the sources of pollution being evident, gave results very different from what might have been expected, and that the inferences drawn from them by many analysts would have been far wide of the facts. While we must say that he went too far in his contempt of microscopic examination, it was refreshing to listen to his outspoken ridicule of arbitrary standards of purity and demonstration of the uncertainty surrounding "albuminoid ammonia," &c. His main theses were that the *normal* chemical composition of the waters in any particular *geological* area must first be known; that any appreciable deviation from this local standard indicates the addition of something from without; that since in practice the pollution always consists of excreta, &c., and not of pure albumen or other unmixed organic matter, and the organic admixture is inevitably accompanied by inorganic substances; and since these can be estimated quantitatively with precision, while the former assuredly cannot, and are, moreover, more characteristic of the particular source of pollution, it is obviously safer to take as our guide the whole of a fixed and definite, than an unknown part of an uncertain and ever-changing substance. The phosphates almost always derived from organic pollution and the sulphates, if in excess of the normal of the locality, afford at least as valuable indications as the chlorides and nitrates, while albuminoid ammonia, free or saline ammonia, nitrites, and nitrates are but various forms of organic nitrogen, representing different stages of decomposition and oxidation, and will be found in varying and generally inverse proportions in the same sample of water at successive periods. Of course, he referred to the researches conducted by himself and Mr. Otto Hehner on nitrification which, as he has shown, is evidence of active bacterial agency actually going on, and not of *previous* in the sense of *remote* contamination, since it proceeds most energetically when the soil, sodden with sewage, is converted into a nitric bed. Again, since the disease germs, the organisms, whatever they may be, to which the dangerous consequences of organic pollution are really owing, are living bodies, it follows that *some* of the most refractory organic matter is more injurious than *any* of the more unstable, dead, and decomposing matters can possibly be; but that since they appear in the same form of albuminoid ammonia as fresh and undecomposed animal or vegetable matters only in infinitesimal quantities, the evidence afforded by this test is of the most uncertain kind. The salts, too, are more uniformly diffused than the organic and organised matters can be, so that, in short, since wherever we have sewage and similar pollution we may have specific or non-specific germs indistinguishable from one another, and we shall have organic matter in one of its Protean forms, none of which can be wholly estimated, and which will probably be unequally distributed, we shall always have a certain number of salts uniformly diffused, capable of precise estimation, and in excess of those natural to the water. When, then, the original values are deducted from the quantities found, we have positive and sufficient evidence of organic pollution, and a fair clue to its nature and source. An obvious moral that Dr. Ashby drew from these considerations was that provincial medical officers of health should be the local water analysts, as by making themselves acquainted with the normal characters of the waters of their respective districts they would be better able than strangers to recognise deviations therefrom.

The President and Council of the Medical Society of London have issued invitations to a *conversazione*, to be held at the Society's Rooms in Chandos Street on Monday, May 5th. The annual oration will be delivered at 8.30, by Dr. Charles Theodore Williams, an announcement which will be received with pleasure by the profession, as proof that the orator has fully recovered from the effects of the severe illness by which he was so recently prostrated.

The spring meeting of the Medico-Psychological Association will be held at Bethlem Hospital on Tuesday, May 6th, at 4 p.m., when Dr. Hayes Newington will read a paper on "Unverified Prognosis"—a subject which might be usefully considered more often than it is in connection with other specialties; and Dr. Bonville Fox will read a paper on "Exaltation in Chronic Alcoholism." The important practical subject of the "Transference of Lunatics of Foreign Nationality to their own Countries" will be introduced by Dr. Mercier, who will submit some resolutions in connection with it to the members of the Association.

The Association of Medical Officers of Schools, which was founded last week, appears to be starting under sufficiently favourable auspices. Amongst those who attended the preliminary meeting were the medical representatives of the larger schools of every class from all parts of the country. The interest and appreciation which the movement has already excited is shown by the fact that although it was possible in the first instance to address only a limited number of medical officers of schools, in the strict sense of the term, favourable replies have been received in the proportion of nearly forty to each fifty circulars sent out. The constitution of the Society is more liberal than its title might seem at first sight to indicate: *all* medical men whose special work lies or has lain in dealing with the ailments of children and young persons, are eligible as members, whatever be their nationality; and it is hoped that much valuable knowledge may thus be gathered in from all quarters, and made at once available for practical application to the good of the rising generation, with a rapidity and method which no other machinery could so easily or so certainly assure. The outside public is already roused to a widespread if not too intelligent interest in hygienic matters; and it will be quick to see that the practical hygienic care of its growing sons and daughters is something which—if duly carried out—bears an immediate pecuniary return, in addition to a store of future health and happiness. But hygiene is a subject as wide as the human nature with which it has to deal; and any means by which the required information may be sooner gained, better sifted, and more certainly applied, should be welcomed and supported by all who are interested in the mental, moral, and physical welfare of the generation which will succeed to their responsibilities and which will judge how these have been hitherto discharged.

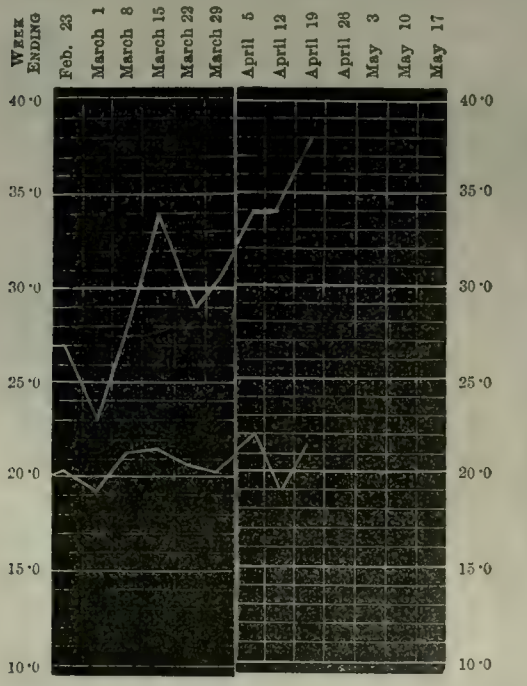
The American Medical Association will hold its Annual Session at Washington the week after next. In the Section of Practice of Medicine, of which Dr. John V. Shoemaker, of Philadelphia, is the chairman, several interesting subjects will be considered. These will include—(1) A discussion on "A Contribution to the Clinical Study of Epilepsy," opened by Professor William Pepper, of Pennsylvania. (2) A discussion on the "Clinical Study of the Heart Sounds," opened by Professor Austin Flint, sen., of New York. (3) A discussion on "Tuberculosis," opened by Dr. Henry F. Formad, of Pennsylvania. Many interesting contributions are also promised, including papers by Dr. Austin Flint, jun., on the "Dietetic Treatment of Diabetes Mellitus," by Dr. Griswold on "Irregular Apoplectic Attacks from Other Causes than Hæmorrhage and Embolism," and by Dr. H. O. Marcy on "The Germ-Theory of Disease."

During the Congress the Association of American Medical Editors will hold their annual meeting, when the annual address will be delivered by President Leartus Connor, M.D., on "The American Medical Journals of the Future, as indicated by the History of American Medical Journals in the Past," and Dr. N. S. Davis will open the discussion on "How far can Legislation aid in elevating the Standard of Medical Education in this Country?"

If it were desirable to add another to the many societies which exist in this country in connection with our calling, we might, with considerable advantage, follow the American example and start an association of medical journalists. We cannot, perhaps, boast of the immense journalistic activity that distinguishes our transatlantic brethren, but there are few physicians and surgeons of eminence who have not been at one time or another connected with a medical journal, and most would probably admit that the literary discipline and encouragement afforded by such work have had no small share in promoting their later success. This journal itself has at different times reckoned among its staff many of the men who are now regarded as the most eminent in the profession, and it would be a great advantage to those of us who are at present striving to the best of our power to follow in their footsteps, and to gather up and disseminate the best thought of the profession, if we had from time to time the opportunity of meeting these past masters in the art, and receiving from them encouragement, instruction, and advice. There is one weak point in connection with medical journalism, regarded from the purely literary point of view, and that is that by the time that a writer has trained himself into habits of accurate thought and happy literary expressions, he is almost invariably compelled to give up his journalistic work in favour of that more remunerative if not more honourable employment, which is the natural goal of all medical practitioners. We do not know that we would have it otherwise. The formation of a larger special class devoted to medical journalism would no doubt have the effect of raising the standard of literary composition, but it would lessen the influence of the journals, because the reader would no longer be able to feel that they were written by men with the same practical interests and experience as himself. If, however, there existed some mechanism which would enable those engaged in medical journalism to meet and discuss topics of medical interest, to hear the criticisms, and the larger and more settled views of older men, and to receive from them encouragement in their work, the difficulty we have above alluded to would be in some measure surmounted. Such help is now in many cases secured informally; to establish it as a recognised principle would do more than anything else to raise

the tone of medical journalism in this country, which, with all due respect to our contemporaries and ourselves, is not beyond the bounds of possibility.

Last week the general death-rate of London rose again to over 21 per 1,000, viz., to 21·4, and the zymotic death-rate sprang up to 3·8 per 1,000, by far the highest rate recorded for weeks. But though the



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of last quarter, and the first two weeks of the present quarter.

number of zymotic deaths, 292, were 52 above the ten years' average, the total deaths were still as many as 89 below the average. Of the zymotic diseases, measles, whooping-cough, diphtheria, and enteric fever were more fatal than usual in the corresponding week of the year; and small-pox, scarlet fever, and diarrhœa less so. Eighteen fatal cases of diphtheria were registered during the week in London, compared with only six registered in the other 27 great towns. The deaths from measles and whooping-cough have steadily increased during the last five weeks, the numbers in the successive returns being as follows: measles, 49, 56, 60, 63, 79; whooping-cough, 101, 112, 125, 124, 129. The first appearance of warm weather may be expected to send down the zymotic death-rate with a run.

The meeting of the Medical Congress which has taken place during the present week at Berlin will be noteworthy, apart from the intrinsic value of its own work, for the peculiarly fitting opportunity which it has afforded for the celebration of the Jubiläum of its President, Professor Theodor von Frerichs. Occupying the position of Professor of Clinical Medicine for twenty-five years, Dr. von Frerichs has so thoroughly associated his name with that department of study that it may be pardonable if the younger generation of scientific men have come to look upon him only as a great clinician, and have left out of sight the labours of his earlier years which paved the way for the greater works of his maturity. For the twelve years preceding his call to the University of Berlin in 1859, Frerichs had in turn distinguished himself in general and ophthalmic surgery, pathology, therapeutics, and chemistry. In the last-named subject especially, his published works on the changes taking place in organic substances before their excretion in the urine, amongst others the presence and importance of leucin and tyrosin in acute yellow atrophy of the liver, were, and still remain, of the highest scientific value. His later works on the processes of digestion, on Bright's disease, and on diseases of the liver, have become standards of medical teaching, even in other countries than his own. The influence of his clinical method upon the numerous students of all nations who have for many years past been privileged to attend the daily work of his Klinik, cannot be estimated at the present time; but there can be no doubt that the habits of close observation, of thoughtful investigation, and careful experiment which have characterised his labours throughout, must have exercised a powerful influence for good, an earnest zeal for worthy imitation, in very many of his pupils now actively following in his footsteps.

We suspect that but few of our medical brethren, and indeed that not many of the public, are aware that so long ago as in the first days of February, a Bill for the regulation of Cremation was introduced in the House of Commons by Dr. Cameron, Sir Lyon Playfair, and Dr. Farquharson, and was read a first time. It is very important that the Bill should not come on for its second reading before the Members of the House have been well instructed as to its aims and defects, and we, therefore, propose to notice its chief provisions. The measure has two objects: "to provide for the regulation of cremation, and other modes of disposal of the dead"; and the latter of these two objects is dealt with first. Clause 4 provides, that it "shall not be lawful to bury, or procure to be buried, the dead body of any person until the death of such person has been registered, and a certificate of registration has been issued in accordance with the provisions of the Registration Acts." And by Clause 5 it is further provided, that whenever it is proposed to register a death without the production of a legal medical certificate of the cause of death, the registrar shall delay issuing a certificate of registration, and shall at once give notice to the medical officer of health, who shall proceed to ascertain the cause of death. If this officer is able to give the required certificate, the registrar will be obliged to issue his certificate of registration; but should the medical officer of health be obstructed in proceeding to ascertain the cause of death, or be unable for any reason to certify the cause, he is to give notice to the coroner, who is to proceed to hold an inquest upon the body, as in a case of sudden death; and it is proposed that the medical officer of health shall be entitled, for the discharge of these duties, to a fee of *five shillings* from the person requiring the death to be registered.

These clauses of the Bill, if workable, would no doubt be sufficient to secure that no corpse shall be buried without the production of the medical certificate of the cause of death; but it may be questioned whether the fee proposed to be given to the medical officer of health is sufficient for the work required of him; and whether it will always be possible for him to obtain the fee from the person made liable for it. And it may be suspected that the promoters of the Bill are doubtful whether the clauses quoted will be workable, as they propose that they shall not apply, "except in the case of persons dying within any urban sanitary district in England or Ireland, or any burgh in Scotland, containing according to the last-published census for the time being a population of five thousand and upwards."

Two special provisions are proposed for the purpose of securing the second—and it may be supposed the main—object of the Bill, viz., the due regulation of remation. Clause 7 provides, that it shall not be lawful "to burn or dispose of, otherwise than by burial, or procure to be burned or disposed of otherwise than by burial, the dead body of any person (1) until the death has been registered in accordance with the provisions of the Registration Acts, as amended by Clause 8 of the Bill; and (2) except in a place licensed for that purpose by a Secretary of State, and in accordance with regulations which shall, from time to time, be made by a Secretary of State." Clause 8 provides, that in all cases in which "it is intended to burn or dispose of, otherwise than by burial, the dead body of any person," a special form of certificate of the cause of death, signed by one or more registered medical persons, shall be produced to the registrar of deaths; and this special form of certificate commences thus: "Knowing that this certificate is desired with a view to the cremation of the body of the deceased person to whom it relates, and knowing the responsibilites imposed upon registered medical persons granting such a certificate"; then follows the form usual in certificates of the kind; and, finally, the granter certifies "that the evident cause of his (or her) death was ———; and that there is no doubt in my mind that the death took place from natural causes, and no reason whatever to suspect that it was caused or accelerated by any criminal act."

Will this new certificate of death really make the legalisation of cremation, as a mode of disposal of the dead, a safe proceeding? Will it effectually take away from cremation the reproach, that it may be used to cover, and to for ever destroy the proofs of a crime? We trow not. Would a Palmer, a Smethurst, a Pritchard, or a Lamson, have felt the slightest hesitation in filling up and signing, in the most orthodox manner, such a certificate in the case of any victim to their skill? No one can believe its formal and particular declarations would have the very slightest deterrent effect with such men; while, on the other hand, honest practitioners will always use as much care and consideration in filling up the old and simpler form of certificate, as they would employ in supplying the cremation-certificate, if we may so call it by way of differentiation. The only value we can credit the latter with is, that it might in some perplexing and suspicious cases encourage a conscientious practitioner, and strengthen his hands in demanding a *post-mortem* examination. Is the other safeguard offered by the Bill, the regulations to be drawn up from time to time by a Secretary of State for the management of the crematorium, and endorsed by the Houses of Parliament, likely to prove of any greater value? No one can say, until the possible scope of these regulations is known. If they are intended only to regulate the arrangements of the place licensed as a crematorium, and the management of the process of cremation, they will avail nothing to make cremation, from the point of view of the public safety, a perfectly safe and desirable process of disposal of the dead.

We will add one more remark before leaving the subject for the present. It has been suggested to us that if all bodies were duly encoffined as now, and then stored for three months in dry vaults or chambers, they might then be cremated without the slightest hesitation, as suspicions as to foul play would have arisen by that time, or would never arise. Perhaps such a precaution might be accepted as partly satisfactory, or very nearly so; but would there not be a serious difficulty in cities of any great size, in storing, temporary and carefully, the mortality of three months? The average mortality of London for three months would be over 16,000, we imagine. Then, when is the funeral service to be performed? Nobody could endure postponing it till three months had elapsed; and few, we suspect, would entertain the dea of having the service at the usual time, and then leaving the body with the knowledge that the burial by fire would only take place three months later. We do not think that this suggestion offers an acceptable solution of the real difficulty in the adoption of cremation.

We recently adverted to some proposed changes which the Council of the College of Surgeons have in contemplation, as well as to others which were suggested to them by the Fellows and Members in public meeting assembled. We suggested that the proposed changes were just to the Fellows and Members at large; that they would be advantageous to the College, and conducive to its general prosperity, and as a secondary result would tend to engender a feeling of *esprit de corps* in a large and important Corporation of scientific men. There now is abundant evidence that the subject of a revision of the Charter is attracting considerable attention, and that there is a determination among Members of the College to secure for themselves a more adequate consideration at the hands of the Council than has hitherto been considered necessary by that body. Apart from the proposed Association of Members, which is in process of formation, there is among Fellows also a feeling that the Members should have some say in College management; the idea once started and backed up by the additional weight of such an opinion on the part of the Fellows, its early realisation is but a matter of time. We can only hope that these matters will receive the fullest and most unbiassed consideration of the present Council at their next meet

ing, when the report of the recent meeting of the Fellows and Members will be on the agenda. Our contemporary, the *Lancet*, has published letters from Mr. Charles Hawkins and Mr. G. D. Pollock, dealing with the subject in a very broad and liberal spirit; we would commend them to the Council, as a basis on which to legislate; for we can hardly doubt that half measures will give rise to a feeling of dissatisfaction, which will find practical expression in one way or another.

On Monday last a deputation of the Governors and Medical Staff of the so-called Government hospitals in Dublin waited upon Lord Spencer, to bring under his notice the dilapidated condition of the Richmond Surgical Hospital, one of the institutions under their charge. This building, which is over two hundred years old, and was never intended for a hospital, is in a most deplorable condition; its walls are crumbling, its sanitation is described as abominable, and the surgical staff are constantly complaining that they have the greatest difficulty, after successful operations, in bringing their patients safely through the period of convalescence from the want of proper ventilation and of an improved system of drainage. It is supported by a Government grant, but the Governors have no power to employ any of this grant in the maintenance of the building, which has therefore gone from bad to worse. The Government have more than once refused to increase the grant, and the Board of Governors do not propose to ask for further annual contributions from that source. All they ask for is a loan, for the purpose of putting the hospital in repair, and they propose to repay the loan and interest out of the present grant. The Lord Lieutenant doubted whether this would be possible, and he suggested, as an alternative, that the annual grant should be commuted and the Governors thereby placed in such an independent position, that they would be more likely to obtain voluntary support. When the Government grant was made it was expected that the hospital would be partially supported by voluntary contributions; hitherto Government support appears to have dried up the spring of private benevolence. That is the one argument against State subsidies.

The Managing Committee of the Glasgow Royal Infirmary which, be it remembered, is the chief hospital in the third largest city in the United Kingdom, have not in past times won a very high reputation for their show of deference to the feelings and opinions of their medical coadjutors, even on points on which at all other hospitals such deference is shown as a matter of course. Only a few months ago, in the chloroform controversy, the Chairman of the House Committee of the Infirmary attempted to ride rough-shod over the medical staff, with the most cynical indifference to their feelings. And now, again, the same thing is happening in the question of dimishing the number of physicians to the Infirmary. Last year the Chairman was compelled to send in his resignation, but a peace was subsequently patched up, and in consideration of his great services to the Infirmary he was allowed to resume office. We received for publication at the time some able communications, containing forebodings of further troubles; but, faithful to our principle of favouring temperateness of speech and kindliness of feeling, which are essential to the successful working of such a complex institution as the Glasgow Royal Infirmary, we suppressed them, and allowed ourselves to hope that the difficulty would not recur again. We were too sanguine; within the last few weeks we regret to hear there has been a recrudescence of the same old despotic spirit. Again, a question in which the opinion of the medical staff and the medical members of the Managing Committee is entitled to the greatest weight, if it may not claim absolute finality, has been decided against them by the lay members of the Committee in deference to the dictation of the same one-man government that was at the root of last year's difficulty. In this case we are informed the medical staff were not even consulted on the subject before the resolution was passed. Surely, if there is one point in hospital administration on which professional opinion ought to be received with due deference, it is as regards the amount of work and responsibility which may fairly be apportioned to each member of the medical staff. If, as is the case at Glasgow, the medical members of a committee are all but unanimously of the opinion that there ought to be such and such a number of physicians to undertake a definite amount of work, that opinion should be the main factor in influencing the votes of their lay colleagues. But this principle, it appears, is not recognised at the Glasgow Royal Infirmary, where the number of surgeons has been increased at the expense of the physicians' appointments, altogether in the teeth of the wishes and well-weighed opinion of the medical supporters of the charity. No institution can expect to prosper where such a cynical disregard is shown for the judgment of those on whom its efficiency is mainly dependent, and we make bold to say that in no other hospital or infirmary in the kingdom would the lay authorities have considered it decent so to over-ride the wishes of their medical colleagues.

The fact that the Committee of the Glasgow Royal Infirmary has for the second time proclaimed its revolt from the tacit understanding, by which all other similar charities consider themselves bound, forces one to ask whether there exist in the conditions of medical practices at Glasgow such exceptional circumstances as will account for this exceptional treatment. Past experience has shown that when the medical profession has been slighted, it has almost invariably had itself to thank for it. Is it so in the present case? Do the medical profession in Glasgow pull together with that firm loyalty to each other, which is to be expected of those practising under the shadow of a large and flourishing University, and in one of the wealthiest centres in the country? Do they all and always by their speech and conduct claim that deference from the community to which their culture and position entitle them? Do they demand in exchange for their professional services such remuneration as their brethren in other parts of the country have decided to be the fair wages of skilful and faithful work? The question of fees may seem at first sight to be altogether

foreign to the matter under consideration; but in a commercial community like Glasgow the tendency is always to value a thing at the price that it can be bought for; and if a merchant can purchase the best professional opinion for the price of a bottle of champagne, or a pair of gloves, he is to be excused if he comes to think that the opinions of medical men on other points are worth even less than that. In many fields of study Glasgow practitioners are doing scientific work that will bear comparison with that done in any other centre of medical activity, and yet some of these same practitioners, we are told, allow their richest patients—who can well afford to pay the fees demanded elsewhere for medical services, and who, when they happen to be elsewhere, pay them without a murmur—to fix the scale of payment themselves, and to remunerate the services of their medical advisers with as much or as little as it may be convenient to them to pay. Such a system, if it prevails, renders it impossible for the members of the profession to claim due weight for their opinion on any point. A medical man ought to be able to live on a scale of comfort bearing some proportion to the expenditure of those amongst whom he lives. If he cannot, then there is something wrong in the relation between supply and demand, or some disproportion between the profits of his profession and those of other callings. It may be said that this is a commercial view of the question, and that science and culture ought to be duly valued, even if they were reduced to living in the tub of Diogenes. Possibly it is a commercial view; but, remember, it is meant for application in a commercial community.

The scientific knowlege and literary skill of the medical profession is to be largely drawn upon in the compilation of the handbooks which will be published in connection with the International Health Exhibition. Dr. Acland will take "Healthy Villages," a subject to which he has devoted years of thought, and on which he has given frequent lectures to young men and maidens at Oxford. Dr. Poore will impress on those of his readers who are householders, their moral obligations in respect to the sanitary state of their holdings. Prof. Corfield and Mr. Watson Cheyne will take a more technical line in their "Laboratory Guide to Public Health Investigation." Dr. Duclaux, who is to write on fermentation, will be introduced to the British public in a preface by M. Pasteur. Dr. Arthur Gamgee, who needs no such introduction, will deal with the physiology of digestion. Mr. Wynter Blyth will write a handbook on Food, and Dr. Cheadle will contribute a preface to Miss Wood's pamphlet on "Cookery for Infants and Invalids." Other medical writers are Mr. Charles Paget, "Healthy Schools;" Mr. James Cantlie, "Accidental Injuries, their Prevention and First Management;" and Surgeon-Major Evatt, "The Ambulance." Altogether the scientific propaganda of the Exhibition may be said to have been placed in very competent hands, though we should like to have seen Sir William Gull, Sir James Paget, Sir Henry Thompson, and Mr. Pridgin Teale amongst the contributors. A handbook, too, by Sir Andrew Clark on "Diet for Dyspeptics, with some Notes on Tea-making," may be regarded as a desideratum.

An exceedingly good *resumé* of the present state of our knowledge of the action of hyoscyamin, is to be found in the American *Journal of Neurology and Psychiatry* for November, 1883. It is written by Dr. Brower.

An interesting discussion on pneumonia recently took place at the Liverpool Medical Institute, a full report of which is given in another column. We have so lately discussed the question of the contagiousness of pneumonia, that it is unnecessary to re-open it again. The evidence before us is as yet too meagre to warrant dogmatism on the subject. We must wait for more research, and meanwhile keep an open mind. One point of the highest importance, however, was brought out in the Liverpool discussion, viz., the great fatality of pneumonia in adults. Some teachers in London, misled perhaps by the comparative harmlessness of the affection in children, have taught of late years that pneumonia is, under rational treatment, a disease with a low death-rate, and have been inclined to attribute the fear with which their predecessors regarded it as due in large measure to the murderous results of blood-letting. They are wrong. Pneumonia in adults is almost as fatal as typhus in adults. It kills not far off thirty per cent.

We publish in another column a letter from Dr. A. H. Jacob, criticising our last week's note on University students and the support of the Corporations' museums and libraries. In this connection the important question seems to be what are the University examinations which an under-graduate must have passed, according to Clause 36 of the Bill, before he can obtain admission to the final examination of the Board. Dr. Jacob may have had better opportunities of knowing what was in the mind of the draughtsman of the Bill than we have, and if it is intended that a student should be able to obtain exemption from the higher scale of fees simply on his showing that he has passed a preliminary and an insignificant Arts examination, we willingly admit that the clause will work an injustice. If, on the other hand, it is intended, as we believe, that the under-graduate, in order to obtain admission to the final examination of the Board, must have passed all the medical examinations of his University, though his graduation for some reason or other may have been deferred, then we submit it would be as unfair to the Universities, as in the other case it would be unfair to the Corporations, to make him pay for the support of the museums and libraries in addition to the heavy fees he has already paid his University. It is hardly likely that these University fees will be less than the small proportion of the Board fees which will go to the support of the museums, so that in no case would University students obtain the right to practise for a smaller expense than other students. Take the case of the University of London, if Dr. Jacob will permit us to use the term. This University has to support a library and extensive buildings, including laboratories and dissecting rooms, on a scale necessary to the thoroughly practical character of its examinations. Hitherto it has had the privilege of granting the right to practise, and though it has been

able to charge comparatively high fees, these fees have never anything like covered the expenses of examination. It is now required to give up this privilege, and Dr. Jacob asks, in addition, that its graduates shall be in future compelled to pay towards the support of libraries and museums, which they now need have nothing to do with. As a matter of fact, the great majority of London graduates do take a diploma in Lincoln's Inn Fields or Pall Mall, and so contribute to the support of the Collegiate museums and libraries. But there is all the difference in the world between voluntary and compulsory support. Dr. Jacob would have found a much more popular cry, and one that we should have heartily joined in, if he had suggested that the State should have solved the difficulty by itself undertaking to support the museums and libraries, the completeness of which is certainly a national interest.

Mr. Knowsley Thornton removed a cystic spleen, by abdominal section (median incision), at the Samaritan Hospital on Thursday, the 22nd inst. The patient was a single girl, aged nineteen, and the tumour had been growing slowly for two years. Latterly it had increased much more rapidly, and caused much pain. Up to Thursday morning the patient was progressing quite satisfactorily. During the tying of the pedicle the patient suffered severely from shock, and for some minutes her life was in great danger; but she revived immediately the tumour was cut away and the drag taken off the pedicle. The specimen will be shown, and the further progress of the case reported at the Pathological Society.

Our Australasian brethren are at present engaged in opposing a Medical Bill which has recently been introduced into the New South Wales Parliament. Their disapproval of the Bill does not surprise us, nor will it surprise our readers when they learn what one of its clauses proposes to do. Clause 7 proposes to admit to the ranks of the profession two classes, viz., those who state that they have had medical study of not less than four years' duration, and those who have practised in the colony for not less than five years. As to the first class not a word is said as to the kind of hospital at which the study is to have been carried on; and as to the last class we are told that they will have to pass an examination at which "the candidate shall be required to show an acquaintance with the structure and functions of the human body"; and also to show "a competency to treat ordinary cases of accident or illness." This is, indeed, a minimum standard; but the Bill proposes a yet lower one: in that by the next clause it is to be enacted "That all unqualified persons who have been in practice in the colony ten years are to be placed on the Register." No wonder that two meetings of the profession were held, at which resolutions were passed condemning the Bill, and that an influential deputation represented their views to the Colonial Secretary. We trust, that in the interest both of the public and of the profession, the Bill, in its present shape, will never become law.

In illustration of the singular way in which the financial affairs of the Paris hospitals are managed, Dr. Richelot, the editor of the *Union Médicale*, tells a curious anecdote (April 10th). We recently gave, from the same source, some examples of the "pound-foolish," and here is one of the "penny-wise." A man having fractured his spine by a fall from the fortifications, and the hospital to which he was brought not possessing the mechanical bed requisite for his treatment, the *chef de service* went to M. Quentin, the Director of the Assistance Publique, and endeavoured to explain to him that the bed was not an object of luxury but an absolute necessity for a hospital. The Director replied, "you must not think of it, it is too dear, you must hire one." In vain was it represented that to hire the bed would in the end be more expensive than to buy it outright, the Director was obdurate, and the bed had to be hired whenever it was wanted. It had always to be waited for, and if used only for three days a month's hire had to be paid, so that between December, 1882, and April, 1884, the maker received 287 francs, that is to say, twice the value of its original cost. If this is to continue, the Assistance instead of paying a little more than 100 francs for its purchase will have to expend 215 francs (5,521 francs at 3 per cent.) per annum for this bed, which will soon become famous. "Paying for an object about thirty-six times its value, and yet never having it at hand, is a fashion of economising which calls for no remark." The same *chef de service*, having requested of the administration a box of instruments, to cost 120 francs, was refused on the plea that the budget of the hospital was exhausted.

Two most important appointments in connection with the study of pathology are now vacant, and will be filled in the course of the next few weeks. The Royal College of Surgeons are ready to receive applications for the post of conservator of their museum, which has just been vacated by Professor Flower. The appointment has hitherto been held by men of the highest scientific attainments, and is one which offers exceptional facilities for study, though but limited opportunities for original research. There will be no lack of candidates, and the decision of the Council of the College will not be an easy one. The electors to the other vacant post—the new professorship of pathology at Cambridge—will probably find their task equally difficult, though for different reasons. They have, in the first place, to decide what manner of man they want. Do they wish to have a teacher of pathology, who will be able to send up their students to the London hospitals well-grounded in the elements of pathology and prepared to make the best use of the rich material which will be placed before them in the hospital *post-mortem* rooms? Or will the electors prefer a pathological investigator, whose researches may win fresh fame and lustre for his University, but who will regard his teaching functions as a secondary matter? If the electors have the interests of the medical school at heart, there can be no doubt that they ought to give the preference to a man who has shown himself a skilful and conscientious teacher. For important as scientific research is, if it is to be subsidised, it ought to be paid for as what it is, and not

under the shadow of something else. But whatever ideal the electors may have formed of the future Cambridge professor of pathology, they will, no doubt, be able to gratify it from the strong list of names which will be presented to them. Dr. Roy of the Brown Institute, Dr. Creighton, Dr. Coats of Glasgow, Dr. Hamilton of Aberdeen, and Mr. Charles Stewart of St. Thomas's Hospital, are said to be candidates for the chair. Several of them have obtained high reputation for independent research, but as an experienced and successful teacher of pathology, Mr. Stewart has a record which none of his competitors can match. His very success in this field has alone been the cause of his not being more publicly known, and we feel sure that there is not one of his past or present pupils—many of them University graduates—who would not sincerely congratulate the Cambridge Medical School on the addition of such an earnest worker and enthusiastic teacher to the ranks of its professors.

"SANITARY ASPECTS OF LONDON GOVERNMENT."

A RESPECTED contemporary published last week a leading article with this attractive heading, but unfortunately the writer having excited the curiosity of his myriad readers, to hear something of "sanitary aspects," forgot to gratify it, and confined his attention entirely to a general criticism of Sir William Harcourt's Bill. And yet if there is one class of considerations, which would alone provide an ample argument for the reform of London Government, and which should fire the imagination of a medical writer, and speed his pen, it is those very sanitary matters which have slipped out of the purview of our contemporary. We will attempt, as far as our own dull imagination and stumbling stylograph will permit, to take up the matter where he left it, and to set down the few common-place thoughts that we owe to the suggestive title we have borrowed. Sanitary questions are of very different qualities. Some appeal to the meanest capacity, while others, more abstract in character, require for their intelligent appreciation the highest order of intellect and culture. A common vestryman in the presence of a raging epidemic will appreciate the necessity of withstanding it by an extra expenditure of funds and energy ; but the more abstract considerations connected with the prevention of such crises will fail to make the slightest impress on his sparse and torpid brain-cells. Such considerations appeal in all their strength only to men with statesmanlike foresight and broad habits of thought. Nothing is more disappointing to the members of the medical profession than to find views with respect to disease prevention, which appear to them, with their special training and experience, most vital in their importance and most impressive in their truth, failing to rouse an equal echo in the minds of even highly trained thinkers, bred in other schools of thought. The medical view of insanity, and the medical view of vivisection, which appear to all medical men, with but a handful of exceptions, so entirely reasonable as to be beyond the possibility of contravention, are but grudgingly—if at all—accepted even by the more cultured of the laity ; and the same is true of many articles of sanitary belief. Even now, the most important measure that could be undertaken in the interests of the health of posterity—the establishment of a State institution for scientific enquiry into the causes of disease—would if proposed in the House of Commons be, to a certainty, pooh-pooh'd by the Government, and laughed down by its supporters. Thus while there are points in the Sanitary Evangel which appeal with irresistible force even to Bumbledom, there are others which are as yet almost too abstract for Downing-street. Between them there are questions of every degree of abstractness, and—we now come to the practical application of this exordium—the higher the class of mind that is drafted off to the every-day business of sanitation, the more hope we have that the vital sanitary interests of such a hive of men as London will meet with due appreciation.

The most admirable feature of Sir W. Harcourt's Bill is that, if passed, it will in all probability take the sanitary administration of the metropolis out of the hands of petty shopkeepers and place it in those of a better class of men, who, though they may not prove themselves capable of appreciating and carrying into practice the higher teachings of sanitary science, may at any rate be expected to introduce a less short-sighted policy, and a more dignified mode of procedure, than those for which the present vestries have distinguished themselves. We have an earnest of this in the spirit which the Metropolitan Board of Works, the London School Board, and the Asylums District Board have brought to their responsible labours ; and the new council of London ought to show itself as much in advance of those Boards, as the members of those Boards have shown themselves in advance of the vestries. The task that will be placed before them—the health and prosperity of no mean city—is one that offers scope for the highest human abilities, and the questions that are looming in the future in connection with the sanitary administration of London, are scarcely of less importance than many that engage the Imperial Parliament. The housing of the poor involves questions which—let the Royal Commission settle what it may—will have to be dealt with in a statesman-like manner and with a strong hand. The great smoke-abatement problem, on the successful solution of which the health and comfort of so many future millions yet unborn will depend, is another question involving the gravest issues. Add to these the questions of water-supply, sewage disposal, the provision of open spaces, school-sanitation, food inspection, the notification of infectious diseases, and hospital control, and it is manifest how important it is that the highest order of intellect should be enlisted in their settlement. All this has been for years apparent to every thinking man, and if anything was needed to convert those still unconvinced, it would be found in the ludicrous proceedings in the Common Council last week. If such speeches as were then delivered represent the spirit of the fathers of the City, which at present is admittedly the best governed section of the metropolis, what else could one expect in outlying parishes, but the petty personal strifes and cock-pit manners, that have reigned at one time or another in so many of the vestries. Happily their doom is sealed, and sooner or later, by a liberal or a conservative administration

they will be swept one and all into that crowded limbo into which so many time-honoured abuses have already disappeared.

The questions we have mentioned above are of an order to engage the attention and demand the decision of the Central council, but there will still remain many details of sanitary administration which will necessarily come within the province of the local boards. Principles once settled it will not be difficult to carry out details, but it must be remembered that it is upon the faithful and conscientious work of local administrators, that individual health and comfort must in the last resort depend. The wisest regulations will fail in their effect, if laxly carried into practice. There are many minor flaws in the sanitary administration of London which appeal for the reforming hand. To take one instance, the present system of refuse-removal is a scandal to a wealthy metropolis like ours. In the best parts of London the refuse of weeks is left festering under the dining-room windows until it suits the pleasure of the dust-contractors to remove it. Uncovered dust-carts are allowed to traverse the streets in the busiest hours of the day, scattering their contents broadcast over the passers-by at every swirl of the East wind. How long-suffering we Londoners have been to put up with this scandal all these years, when for no sensible increase of expense this refuse of each day could be put out and removed before we were out of our beds the next morning! Then there is the crossing-sweeper nuisance. We tolerate a crowd of lazy mendicants, supported by voluntary contributions, when for a tithe of the money so expended, we could have every crossing systematically swept by regularly paid sweepers, and not only those which lead to fashionable churches and other places where the wealthy and charitable resort. These are little matters, but how much of our daily comfort, if not of our health, depends on them!

One more consideration. London is our chief of cities, and the reform of its government is confessedly being undertaken by the ministry as the prelude of changes to be introduced in local administration throughout the country. Upon the success of the experiment in the metropolis, the interests of many other centres of population throughout the country will depend. London will set the example to many cities which are now even less fortunate in the matter of local adminstration than herself. If the new Central Council take up a bold and broad policy, if they give due heed to sanitary teaching, and determine to neglect nothing which can conduce to the health and convenience of their constituents, the same line will be followed in a hundred towns scattered up and down the country London will set the fashion, and it will depend upon the fashion she sets, whether the hard lessons of sanitary science shall be learned and followed with good will and enthusiasm, or shall need to be forced upon reluctant authorities by the pressure of the Central government. All these considerations show that there will be scope enough in the future administration of a united metropolis for the highest grades of intellect; scope, too, for that public spirit and willingness to labour unpaid for the public weal for which the more cultured classes of our countrymen have always been honourably distinguished.

THE GRIEVANCES OF JUNIOR OFFICERS OF THE INDIAN MEDICAL SERVICE.

We have received a pamphlet of some sixty pages, entitled *An Appeal from the Surgeons of the Indian Medical Service*, which appears to have been printed during the current year at Lahore. The title sufficiently expresses the character of the publication, but it hardly prepared us for the wholesale abuse of almost everything and everybody officially connected with India. Much as we sympathise with the grievances of Indian Medical Officers, and we have satisfied ourselves by considerable enquiry in various quarters that there are grievances of a serious character, we nevertheless cannot avoid expressing our sincere regret that such a publication as this should have been distributed by a body of officers holding commissions in one of our military medical services. Allowance should, perhaps, be made in that it purports to emanate from the "juniors," and for the bitterness engendered by hope deferred; still the whole tone of the pamphlet bears evidence that at least those concerned in its preparation could not have been the easiest of persons for either governments or individuals to satisfy and control. We venture to express the opinion that but an extremely small minority of the service could have seen the text of the appeal before its distribution. A sentence like the following for example, regarding a recently issued State paper, "that the apparent honesty of the new memorandum excites greater scorn than the Machiavellian duplicity of the old," could surely not have been promulgated with the approval of any representative body of public servants.

Having said so much regarding the manner, we now turn to the matter of the pamphlet. This has to a certain extent been epitomised for us by Mr. Gibson, the member for the Dublin University, in the questions which he asked the Under-Secretary of State for India on the 2nd of this month—(1) Whether the number of surgeons of the Indian Medical Service under and up to five years' service, employed on "unemployed" pay in Bengal alone, was 28 out of a total of 59 surgeons; and (2) whether it was a fact that all these 28 surgeons employed on "unemployed" pay were not only supernumerary to the actual number of appointments, but were even also supernumerary to those surgeons who were only "officiating" for officers who really held these actual appointments, but were at present on leave. Other questions were asked, but these were the principal. In replying to them, Mr. Cross allowed, in effect, that such was the case, and explained that the 28 gentlemen formed a portion of the reserve needed for the medical service, the ordinary reserve to meet furloughs and casualties being 20 per cent. on the number of appointments.

In reality, so far as we can gather, the real grievances under which this medical service now labours, and under which it has laboured for years, is the underpayment of the "reserve." In former years this may not have been felt to so great an extent, but now that the value of the rupee has fallen by nearly one-fourth, at least so far as remittances of payments to England are concerned (and where is the young officer who has not to make such remittances, even though he may

have no family in England to support?) it would be not only a generous, but also a politic act, were the Government of India to say once and for all that, as regards its military medical service at all events, in future *all* officers would be accorded the full-pay of their rank, irrespective of the duties allotted to them. The annual cost of such a concession would, comparatively speaking, be but a trifle to the Government, but from all we can gather, the gain would be great, for it would have a contented body of medical officers at its command, and administrative officers would be able to distribute them in the most advantageous manner to the State, without having to calculate in the first instance, what effect their acts would have on the pecuniary prospects of the surgeons concerned.

We would strongly urge on the Government the advantage which it would derive from adopting such a course. We do not join those who accuse the Government of having knowingly broken its covenant in this matter. But it is evident that the candidates for the service placed a different interpretation on the terms of the memorandum from that which the Government intended them to bear, and their mistake has been specially brought home to them by the block in the service which has resulted from a diminution in the number of appointments. The Government published a certain scale of unemployed pay, and a scale of payment for the various appointments, but in a subsequent paragraph stated that a medical officer, however employed, would be restricted to the unemployed rate of pay until he had passed a certain examination in Hindustani. This, together with another paragraph, appears to have been taken by the candidates to mean that the pay of all officers who passed the examination would be at once raised from the unemployed rate of 286 rupees to 400 rupees per mensem. All that the Government meant, however, was that an officer who had not passed in Hindustani, even if gazetted to an appointment, should only receive the lower standard of pay. It was simply an arrangement for compelling officers to get through their Hindustani examination quickly. Unfortunately and quite naturally, however, it was read otherwise by the candidates; and, admitting this, the Government will be but acting wisely if it makes up to them for the mistake to which its own ambiguous phraseology gave rise. This, however, is not the only complaint of the officers. It would appear that, by a recent order of the Commander-in-chief, junior surgeons of the Indian Medical Service, "whenever they are in excess of the appointments with native troops available for them are to be attached to Station hospitals of British troops, for the purposes of instruction in the illness of Europeans in the country, and for the acquirement of a knowledge of the routine of medical duties in connection with European troops." We cannot agree with the writers of the pamphlet that this is a slur on the members of the service; indeed it seems to us that having the opportunity of seeing on their arrival in the country how the clerical and other duties connected with hospital work in India are carried on should be welcomed as a boon rather than as a grievance, but we would urge that even whilst on such duty the officers should commence to draw the full pay of their rank as soon as they have, like other officers of local corps, passed the required examination in the vernacular.

In replying to one of Mr. Gibson's questions in this connection, Mr. Cross stated that whilst thus engaged, surgeons of the Indian Service drew less pay than those of the Army Medical Department, but this should not be, and the fact that Mr. Cross was able to add that "for the remainder of their service their prospects are much better, and their average salaries much higher," does not diminish the grievance complained of.

We have not space enough to refer to several of the other minor grievances referred to in this *Appeal*, some of which, we must say, appear to us to be of a very trivial character, whilst others are not strictly in accordance with the facts. For example, at page 13 it is written:—"Before finally passing on to the results of our efforts for obtaining our rights, we make a passing allusion to a totally unnecessary farce that is performed at Netley at the end of each term," namely, the announcement that the two senior successful candidates on the list have been specially recommended to the Secretary of State for India. The present edition of the Bengal Army List, it is stated, shows that not a single surgeon who has as yet been so recommended, has obtained a post on the Staff of the Calcutta Medical College. We have looked into this matter and find that of the seven or so professorships at this College, six are held by men who have passed through Netley—the seventh, which carries the Principalship with it, is held by an officer who entered the service before Netley was established. Now of these six, no less than three are held by men who took a *first* place at Netley—Professors Macleod, D. D. Cunningham, and McConnell. Surely the junior members of the service do not expect that, when filling up posts on the staff of such a college, the claims of their seniors should be overlooked by the authorities concerned, so long as such competent men as those above named are to be found amongst them.

As already observed, we have taken considerable pains to look at the questions discussed in this pamphlet from all points of view, and have not hesitated to express an adverse opinion when this seemed to be called for. On the other hand, we do feel very strongly the urgent necessity which there is for the Government to meet the well-grounded complaints in a generous and liberal spirit. *Bis dat qui cito dat.*

SCHOOL PUNISHMENTS.

The Medical Officers of Schools' Association, whose inaugural meeting we chronicle in another column, is not likely to languish for lack of subjects deserving its consideration. Indeed, if the modern school-child were not a child, or if he had attained that precocious development which some authorities would have us believe is being rapidly induced by the modern methods of education, there might be some reason to dread the effect upon him of the keen and general interest with which his present position is discussed. Happily, childhood is not, as a rule, acutely sensitive to the attention which it excites, unless that attention takes a form which is personally offensive; and even to this successive generations of scholars have become more or less accustomed. Discipline is the inseparable companion of instruction, and neither is at all times attrac-

tive; but an examination of some of the means by which it has been sought to maintain the former, seems almost to indicate the existence, in domestic legislators, of a perverse ingenuity in making both of them needlessly repellent.

The history of a nation's civilisation is fairly reflected in that of the various punishments which it has from time to time abandoned, modified, and adopted. As knowledge spreads, morals improve, and manners soften, reformation rather than vengeance comes to be the dominant idea in devising punitive treatment for the ill-doer; and while it is sought to permanently influence the delinquent's character for good, care is taken to avoid lasting injury or mutilation of his person. The rough *tu-quoque* principle which decreed the sacrifice of a hand or of an ear, and which sanctioned the stocks, the pillory, and the "tumbril" or ducking-stool, gives way to the cat for the garotter, hard labour for the felon, and simple incarceration for the "first-class misdemeanant." The more a people learns to realise the value of both parts of man's nature, the more does it recognise that correction is not necessarily identical with chastisement, and that the latter, to be effective, need not be cruel either in application or in result. The more widely such truths have been recognised and acted on, the greater has been the mental and moral progress of the nation at large. This is true of punishment in its social no less than in its legislative aspect; for the public opinion which demands the decent regulation of criminal executions is but an echo of the gentler manners and wider intelligence which find an appropriate field in the training of children at home and at school. To many of us it has been a source of genuine gratification to believe that the more intelligent portion of the public was now pretty generally alive to the fact that the essential organ of hearing is a delicate and fragile apparatus, which may be irretrievably damaged by "a box on the ear;" and we would hope that the knowledge of this fact—and the caution which such knowledge should beget—will, in due time, permeate those other classes of society, amongst whose rough-and-ready methods of administering justice (and injustice) this particular form of personal chastisement still holds a dangerously popular position. On the other hand, we cannot but experience both surprise and regret when we read of a magistrate advising a perplexed parent "to box his son's ears and bring him to his senses," because it is not from such a source that we expect a check to be given to the spread of an intelligent humanity amongst the masses; and we dread lest the rational teachings of civilisation and of medicine should be more than nullified amongst those to whom they are most necessary, by this legal *imprimatur* of a custom to which the thoughtless are, under all circumstances, only too prone. The remonstrances and warnings of the doctor will, for many minds, weigh but lightly against a magisterial statement of the legality—and, further, of the practical advisability—of a punitive method, which possesses the obvious advantages of simplicity and ease in application, and of which the effectiveness can be graduated in accordance with gravity of the offence, or the ire of the castigator, as the case may be. It may be contended that care was taken to ensure the administration of both antidote and poison in the same spoon, since the father was recommended not merely to box the luckless youth's ears, but to "bring him to his senses" (if possible, we presume) afterwards. We would respectfully submit, however, that the successful carrying out of such a line of practice implies a trained discrimination and a delicacy of manipulation, which are usually wanting amongst those who are most likely to attempt it; and that any form of punishment, whose effects on the recipient are such that efforts must afterwards be made to restore him to his senses, is one more honoured in the breach than in the observance.

The mechanism by which—or, at least, one of the modes in which—a blow on the ear or on the side of the head may produce deafness and other forms of ear-injury, was described in an interesting paper on the "Function of the Membrana Flaccida of the Tympanic Membrane," which appeared in *Nature* for December 7th, 1882, p. 129. The writer showed that the upper and more opaque portion of the membrana tympani is comparatively loose, being mainly attached at its margin to the skin of the smooth upper wall of the meatus, and is thus easily displaced by a little gentle pressure outwards or inwards. The lower portion of the drum of the ear is fixed by its connection with the os tympanicum; while the upper portion (membrana flaccida) lying above the handle of the malleus, and having apparently no direct connection with the chain of ossicles, blends, at its superior margin, with a piece of movable skin, which glides on the smooth-polished surface of the upper semi-circle of the bony meatus, and is directly continuous with the movable membranous roof of the cartilaginous portion of the external auditory passage. The movable piece of skin, therefore, serves as a tendon, and the muscle which mainly plays upon it is attached to the upper membranous wall, just mentioned, at its point of junction with the osseous meatus. The muscle in question is, according to Henle, the musculus epicranius temporalis, (occipito-frontalis). Its action is further assisted by that of other small auricular muscles, especially the attolens, and it is brought into play when the eyebrows are forcibly raised by the contraction of the occipito-frontalis. It will be seen, then, that when this muscle contracts, it pulls the membranous roof of the auditory canal upwards and slightly forwards, thus telling upon the membrana flaccida, which is, even in the adult, almost in a line with the upper wall; the effect of this movement is, in opposition to that of the tensor tympani muscle, to draw the umbo or deepest part of the membrane outwards, and thus to bring the tympanic membrane generally into a more vertical plane relatively to the lower wall of the meatus. "This is, beyond all question, its position for acutest hearing; and it is thus important to observe that by the single contraction of the occipito-frontalis muscle both eyes and ears are brought simultaneously into the attitudes of strained attention. Hence, in endeavouring to hear, as well as to see intently, we involuntarily raise the eyebrows in order to tell upon the drum of the ear." It needs no reference to the "knee-jerk" and other familiar reflexes, to perceive how—without the direct action of any violent concussion of the air, such as un-

doubtedly sometimes occurs, *e.g.*, in artillery firing—a smart blow on the side of the head may induce sudden spasmodic contraction of the muscle, and thus, through the action of the mechanism described, bring about serious injury, or even rupture of the drum of the ear.

The faculty of hearing is not the only one which is apt to suffer in childhood through the ignorance or heedlessness of parents and preceptors. It is a tolerably safe as well as a charitable maxim that the stupid child, so called, is in most cases a deaf or an amblyopic one. But the victim of ametropia is still too commonly condemned, by way of punishment for its supposed laziness or inattention, to further and excessive abuse of its delicate and imperfect eyesight, until, perhaps, Nature's indignant remonstrance—in the shape of a "sick-headache"—leads to a parental diagnosis founded on the convenient ætiology of surreptitious toffy or unripe fruit, and to a treatment by castor oil and starvation, which is successful, for the time at least, because it includes the unappreciated factor—rest. There exists another variety of school punishment which a somewhat squeamish humanity affects in preference to any form of corporal chastisement. We refer to the different forms of written imposition. What the exact value of these may be, from a disciplinary point of view, we cannot profess to determine; no one who knows or remembers anything of school-life will pretend that one boy in a hundred so punished learns anything valuable, or in a valuable way, from a passage which he writes as fast as is consistent with tolerable legibility, often from friendly dictation, and with no more acquaintance with its sense or meaning than is necessary for the avoidance of gross and obvious errors; or that he reaps any moral benefit from the "lines" which may sometimes be copied during the hours of regular school work, and which, if a sufficient similarity of handwriting can be assured, may even be contracted for upon one of the many fluctuating bases of school-boy barter and exchange. It is, at least, certain that the custom is one which lays an extra burden upon the child whose play-hours should be devoted to recreation; which tries the eyesight, and tends to dull rather than to brighten the intellectual powers; which favours a stooping habit, contracts the chest, and rounds the shoulders; which keeps the child indoors when he should be out; and which fosters crabbed and illegible cheirography. If such punishments must be worked out during play-hours, then their nature and method should be so contrived, that they may not directly aggravate the necessity for that fresh air and bodily exercise upon which depends the value of play as opposed to mental work. In most of our larger schools, at all events, some such arrangement would not be impracticable. Many of these possess a carpenter's or other similar workshop, in which not a few boys spend much time for their own amusement, and in which, in some instances, they have the advantage of receiving regular instruction. The carpenter or blacksmith would be able to gauge the working capacity of each of his pupils, who might be arranged in classes accordingly; and thus, in place of so many hundred lines, or so many copies of that misconstrued passage, the delinquent would receive the order to saw, square, and plane up so many feet of quartering, to turn a chair leg of a certain pattern, or to forge so much iron work, according to his capabilities and the gravity of his misdeeds. Work of this nature would imply, not merely active, healthy, bodily exercise under good hygienic conditions, but would entail the acquisition of practical knowledge which could not be useless, and which might at any time prove most valuable to its possessor. Its punitive character would be sufficiently ensured by the consideration that it took the place of an equivalent of cricket or of football, &c., and, above all, by the fact that it was compulsory and not voluntary labour. The famous method of Mr. Squeers, who made his pupil, after having spelt "horse," rub it down, deserves something better than the ridicule which it usually provokes. For, after all, was it not a form—crude, it may be—of those "object-lessons" in which all the value of modern scientific education is now said to consist?

Do what we may, however, so long as human nature is human nature still, there will continue to arise from time to time, the necessity for a resort to some form of corporal punishment; and while parents and school-masters continue to exist, and to exercise authority, the question as to its character, and the least undesirable method of inflicting it, will have to be faced. Let us then in the first place, and *pace* the Magistrate, strike out boxing the ears from the list of allowable forms of chastisement. Caning—judiciously inflicted—is infinitely more merciful, and is surely not ineffective; the birch is better even than the cane, while its application is a practical enforcement of the valuable aphorism, "Union is Strength." As regards the exact site of punishment, caning on the palms and fingers is not without its dangers in some hands; and, indeed, the posterior aspect of the human form divine commends itself on all the grounds of mercy, convenience, and æstheticism. Striking the head is out of the question; it is not desirable to introduce the bastinado; blows on the back and shoulders may easily produce needlessly painful and severe results. These objections do not here apply with equal force to the glutæal region. In Gleig's "Life of the Duke of Wellington," it is related that at the battle of Orthes the duke was unhorsed by a ball which struck and glanced from his sword-guard. "He was on his feet, however, again in a moment, and in a condition to laugh at the Spanish General Alava, who had likewise been wounded, almost at the same instant, in that fleshy and very sensitive part of the body, any accident to which is apt to excite the mirth rather than the sympathy of lookers-on." We may conclude, from lack of evidence to the contrary, that the Spanish General recovered from the "punishment" which had in it something of an undignified, because of a puerile character. Fortified by such an instance—not to mention the famous example of the Empress Maria Theresa herself—we would, in the place of head, ears, and hands, earnestly recommend as a more appropriate site for castigation, that portion of the human frame which is sensitive enough to satisfy the sterner demands of justice, and which, at the same time, is so constructed as to sustain with impunity violence which cannot safely be administered elsewhere.

REVIEWS AND NOTICES OF BOOKS.

Traité de l'Affection Calculeuse du Foie; par Dr. Jules Cyr. Paris: Delahaye et Lecrosnier, 1884.—Within the last year or two, Europe, and more especially England, may be said to have suffered from a veritable epidemic of hepatic literature. For, in rapid succession have appeared Legg's work on Bile and Bilious Disorders; George Harley's treatise on Diseases of the Liver, with and without Jaundice; Ruckley's book on Diseases of the Biliary Passages and Portal Vein; a German edition of Harley's treatise by Drs. Kraus and Rothe; and lastly the work of Dr. Cyr, the title of which heads this article. And the marvel to us is not only how all these authors can have found something new to tell us on the disorders of one solitary organ of the body (notwithstanding its being such an important one), but how they can find a sufficient number of purchasers to make their literary speculations profitable. No doubt, the sale of the volumes differs quite as much as the value of their contents. For only two of them, in our opinion, are the offspring of original thought, and these two form a marked contrast to the others (which are mere learned compilations) and may be truthfully said to mark a new epoch in the study of liver diseases. As regards the volume now under review, we may say that, small though it be, it is in our opinion the master-piece of its author, who is already well known as an able exponent of this department of clinical medicine, for in it he has done good service to the profession, by opening its eyes to the fact that gall stones are not only a very common cause of grave disease, but (contrary to the general belief) often lead to fatal results. The reason why the generality of the profession has remained in total ignorance of these facts is not far to seek. It may be said to have arisen from the erroneous teachings of our schools. For how could men diagnose cases of gall stones when they had never been told that the most dangerous cases of them might occur without a trace of jaundice (p. 163), or even pain, and that the only symptom manifested by some rapidly fatal ones, is discomfort in the hypochondrium, associated with some of the ordinary feelings of chronic dyspepsia. For example, a gall stone slowly ulcerating its way out of the gall bladder produces not a vestige of jaundice, and scarcely any pain, though it may be accompanied with considerable tenderness on pressure. Yet it may suddenly kill the patient by opening an artery and producing copious internal hæmorrhage (p. 185). Or cause a speedily fatal peritonitis by ulcerating its way into the peritonæum. Gall stones, moreover, from the mere severity of the pain they excite, occasionally bring about the death of the sufferer by collapse, coma, or convulsions (p. 190). While, again, as our author shows, the immediate cause of death by syncope in cases of heart disease is not unfrequently due to the pain produced by a gall stone, and that associated with hernia to the irritative effects of a biliary calculus in the digestive canal (p. 188). Another useful hint he gives is the calling prominent attention to the frequency with which abscess of the liver, cancer, and also ulcer of the stomach may be said to have been originated by the presence of an impacted gall stone, and at pp. 128–131, he does further service by showing how even distinguished physicians, from their want of a special knowledge of hepatic diseases, mistake the signs and symptoms of gall stones (when unassociated with jaundice) for such stomach derangements as gastralgia, dyspepsia, and ulceration. Hence some of the most important chapters of the book are those devoted to differential diagnosis (p. 128), and the symptoms of ulcerating calculi (p. 241). We cannot close our remarks without calling attention to the chapter headed "Intermittent Hepatic Fever," as it is a subject which few practitioners in this country (beyond those who make liver diseases a special study) know anything about. Dr. Cyr points out how the intermittent fever of hepatic disease, which is frequently met with among us, differs from ague in usually recurring between the fifth and ninth day; the attack commencing in the afternoon or evening, there being generally no rigors; but only a feeling of chilliness, with scarcely any sweating stage; the temperature not exceeding 99°, and the pulse being under 100°. In cases of exceptional severity, however, there are, as in true ague, both rigors and a marked sweating stage, with high temperature, and rapid pulse. The two diseases are, however, even then, by no means identical; for besides the differences they present in the times of their attack they show the still further distinguishing peculiarity that while the one is amenable to the action of quinine, the other not only fails to be benefited, but is often made worse by it (p. 199). Throughout the book there are some most judicious remarks on medicinal treatment, as well as a great deal about the beneficial effects of the waters of Vichy in gall-stone cases; which is natural enough, seeing that its author is one of the medical inspectors of that renowned French watering-place. We cordially recommend its perusal to our readers, as we can unhesitatingly pronounce it the best book on the specialty of gall stones we have yet seen.

Elements of Human Physiology; by Henry Power, M.B., F.R.C.S. London: Cassell & Co.—It is not without a certain feeling of regret that we are obliged to own that this book will have a good sale, and this regret is occasioned by the fear that too many students will be induced to confine their attention to these small manuals, to the neglect of larger and better text-books. We are not in favour of small books which profess to give in small compass what standard text-books take long to tell. The book before us is not without merit; it is neatly got up, clearly printed and possesses good diagrams, and furthermore is written by an Examiner of the College of Surgeons: its sale is thus secured. But let us give the young student a word of warning. Physiology, which in after-life is capable of wider application than anatomy, and which will help the practitioner to solve his clinical problems long after he has forgotten the dissection necessary to expose the chorda tympani, is not to be learnt without a judicious expenditure of reasoning power. That is where small books fail. The anatomical method of cramming facts and learning by rule of thumb is necessarily encouraged. Therefore we say to young students "Avoid all small books, and make your Foster your physiological guide." The book before us may be very useful to the advanced student who, just on the verge of an examination, wishes to refresh his knowledge, but is not to be recommended to the tiro who is in search of general principles. We should have welcomed this book had it been less ambitious, and dealt with elementary things and general principles. There are some parts that require re-writing. Having read it very carefully, we may point out the following defects: The account of coagulation of the blood is very meagre, and no mention is made of the theories advanced by Hammarsten, which are probably quite as correct as Schmidt's. The normal spectrum of blood should have been more fully described. No mention is made of the modern views on the question of cardiac innervation, which are taking firm hold of the physiological world. We object to such loose expressions as that "muscarin and digitalis excite the vagus." Poisons act on the muscle. We think that Martin's experiments prove the internal intercostals to be only expiratory, and this should have been mentioned. A very important omission occurs in the case of asphyxia, which should have been fully described. In the chapter on urine, the so-called qualitative tests are quantitative, and no mention is made of the two well-known crystal tests—the nitrate and oxalate of urea. The description of the estimation of urea by Liebig's method requires re-writing. Not silver nitrate, but mercuric nitrate should be used. Why should soda solution "be added to neutralisation?" The silver nitrate is added to precipitate the chlorides, which otherwise interfere with the precipitation of all the urea. The connection of hippuric acid with glycin should have been mentioned. Why does Mr. Power say "casein, *or* potassium albuminate?"

In the section on the origin of fat, it is stated that it arises by simple storing up of fat ingested, and only partially from carbohydrates and proteïds. Subbotin's experiments show that very little fat is stored in the form eaten, and the carbohydrates must be considered the chief factor in fat production. It is wrong to speak of the submaxillary

ganglion as a centre of reflex action (p. 104). Since Bernard's time many physiologists have been engaged in showing that it is not such a centre. No mention is made of syntonin in gastric digestion, and none of alkali albumen in pancreatic digestion. The latter is said to convert proteïds into *globulin*, but on what grounds is not stated. No mention is made of saponification or emulsification by the bile, but much is said as to its questionable diastatic ferment. Mr. Power states that muscle requires oxygen for the *manifestation* of its activity. This is precisely what it does not require since it works well in an atmosphere of nitrogen, and only requires oxygen for the maintenance of its activity. Protagon should have been described as a compound of cerebrin and lecithin, a phosphorised and a non-phosphorised portion. Glycogen is said to be split into "achroodextrose and ptyalose." What is ptyalose?

We have said enough to show that there are numerous defects, and some bad errors. The book bears traces of hasty writing, and no doubt in another edition some improvements and judicious pruning will be effected. The little volume is a handy one for senior students and others already having some knowledge of physiology. The chapter on the eye is good, as one would expect from so accomplished an ophthalmic surgeon. The little *résumé* of development forming the last chapter is a valuable addition, and there is a useful appendix containing much that is up to the latest date respecting physiological chemistry.

Museum of the Royal College of Surgeons of England. Catalogue of the Osteological Specimens. Part II. Mammalia. Edited by W. H. Flower, LL.D., F.R.S. London: J. and A. Churchill, 1884.—This volume completes the specimens illustrating Human Osteology in the great museum in Lincoln's Inn Fields. The college authorities may congratulate themselves on the termination of this important work by Professor Flower, before his almost invaluable services were lost to the college. The nomenclature to be used in a museum of this kind is always a matter of considerable importance, and the determination to adhere to the Stricklandian Code will probably meet with general approval. As Professor Flower says, the aim in such a work as the present is simply convenience and general accord, and it is often better to put up with a small error or inconvenience in an existing name than to incur the much larger confusion caused by the introduction of a new one. No new names have been introduced, and many generic divisions have been altogether omitted. The number of specimens in this portion of the museum is 3,972, and in every instance, where possible, the locality whence the specimen was obtained is given. References are given to former editions of the catalogue whenever necessary, fuller details being contained in them than in the present edition. There are two alphabetical indices, one giving the scientific names and synonyms, the other the English names.

ABSTRACTS AND EXTRACTS.

THE QUANTITATIVE DETERMINATION OF MICRO-ORGANISMS IN ATMOSPHERIC AIR.[1]

By Dr. W. HESSE.

With the constantly increasing knowledge of the behaviour and influence of micro-organisms in the production and spread of disease, it becomes of the utmost importance to obtain some clear idea of the manner in which such micro-organisms may be conveyed from one body to another. The influence of solids and fluids in the conveyance of infection has been already successfully elucidated, and the task remains to investigate in like manner the extent to which gaseous matters, and especially atmospheric air, are capable of playing a similar part. The processes hitherto employed for this purpose have been unsatisfactory in their results, allowing neither of complete microscopic examination, nor of any approach to quantitative analysis.

In his present research, Dr. Hesse adopted a method which has overcome both these defects. His plan, briefly, was as follows:—He caused a definite quantity of air to pass slowly through a tube of fixed proportions, by means of syphon action, the tube itself being thoroughly cleansed and sterilised before the commencement of the experiment, and its walls covered with a thin layer of peptone gelatine. The aspirating action of the syphons, being under complete control, admitted of accurate measurement of the volume of air passing through the tube, and also of the rapidity of the current. The tube itself, graduated in centimetres and millimetres, was closed at one end by a plug perforated by a single opening for the entrance of air, and at the other by the narrower tube for its exit, the latter tube being furnished with two plugs of gun-cotton placed at a little distance apart, through which the air must of necessity pass to reach the flasks arranged in series, one above another, by which the syphon action was maintained. In his first recorded experiment a small colony of bacteria became developed on the gelatine at the fifth centimetre from the entrance to the graduated tube, within the first twenty-four hours; the quantity of air being at the rate of one litre in 6·4 minutes. On the following day three other centres were observed, and with each succeeding period of twenty-four hours, the number of colonies of bacteria increased in number, and presented themselves at intervals farther and farther along the tube from their point of entry. In a second experiment, in which a larger volume of air was passed in a shorter time through a tube of somewhat greater calibre, the number of bacterial centres formed was more numerous, and at the same time extended much farther along the tube. In neither case, however, did the development of these colonies of bacteria extend, even after four days, over its full length. Dr. Hesse draws the following deductions from these results: (1.) That the current of air in its passage through the tube becomes more and more free from bacteria, until at last it contains none. (2.) That the more slow the passage of the current through the tube, the more are the bacteria found in the neighbourhood of the entrance. From these conclusions he is led to believe, that in the case of the slower current he ensures the deposit of all the bacteria which the air contains, and very nearly all from the more rapid current. In both experiments the micro-organisms, developed farthest from the point of entrance, were fungoid in character, being distinct from the bacterial forms which were deposited farther back. This is explicable only on the assumption that the spores of the fungoid growth are more easily borne in the air, or that the bacteria are carried in clusters, instead of singly, and thus become of greater weight. All the colonies were developed upon the lower half of the tube, which during each experiment was kept fixed in the horizontal position. The fact thus proved is one of very considerable importance, as showing that these micro-organisms are possessed of sufficient weight to cause them to become deposited in still air, and, therefore, that strong currents are essential for their transference from place to place.

In order to prove the complete deposit of all the bacteria in the air under examination, a close inspection of the gun-cotton plugs in the exit tube was made, by surrounding them with cultivation-gelatine similar to that within the tube; they showed, however, no traces of bacteria. In estimating the quantity of micro-organisms thus drawn into the tube, one important factor remained to be considered, viz., the size of the aperture of entrance. After many experiments to test the influence of openings of various sizes, upon the ultimate result, the conclusion was arrived at that an opening, similar in calibre to that of the tube of exit, was to be preferred in all cases.

Having thus constructed an apparatus, in all respects trustworthy for the purpose, Dr. Hesse instituted a series of investigations which will doubtless form the ground-work of a new and most important line of enquiry. Of those recorded in his present paper, the principal experiments were made upon the air in dwelling-houses, hospitals, and amongst building materials, rag-picking yards and dung-

[1] "Reports of the Imperial Board of Health in Germany." Edited by Dr. Struck. Vol. ii. 1884.

heaps. Observations also are recorded of the atmosphere in cow-houses and stables, and in the open air of the town and country respectively. The results obtained, too varied and extensive for satisfactory analysis within narrow limits, will be read with much interest by all who are occupied in the study of micro-organic life. With some disappointment, however, will the statement be received, that this method of quantitative determination of bacteria has not as yet been made applicable to the discovery and isolation of the tubercle bacillus. The difficulties, although fully recognised, have not yet been overcome; but the success which has thus far attended his efforts in this direction renders it highly probable that we shall be able before long to welcome a further contribution from the author, in which this point also will be elucidated.

DERMATOLOGY.

Dermatosis Diabetica.—An address on the subject of the various skin affections met with in diabetes, lately delivered by Professor Kaposi, is published in the *Wiener Medicinische Wochenschrift*, Nos. 1-4, 1884. The case, forming the text for the subsequent remarks, was one of a peculiar and hitherto undescribed form of gangrene occurring in a woman of 51, the subject of diabetes. The affection was confined to the left leg, on which there were found patches of gangrene and bullæ containing turbid serum. The development of the bullæ appeared to be the initial process, gangrene taking place underneath them; but, instead of becoming circumscribed, the gangrene appeared in places to be spreading in a serpiginous manner by the continued falling in of neighbouring islets of disintegrating tissue. In other parts a partial healing and cicatrisation had taken place. Dr. Kaposi gave to this case the descriptive title of Gangræna bullosa serpiginosa. The diagnosis of its diabetic origin was arrived at by a process of exclusion. The only other form of gangrene liable to be confused with it was that due to neuritic changes, but the distribution of the patches sufficed to negative that supposition. By special treatment the diabetic symptoms were reduced, and a partial improvement took place in the spread of the gangrene, but a few months later, the gradual return of the glycosuria was accompanied by a steady advance in the gangrenous condition, leading to death within six months of the commencement of the skin affection. Throughout the illness there was no fever, severe and continuous pain, however, had always been present. The treatment was chiefly symptomatic, and the only local application which gave any relief was olive oil and lime-water. Passing in review the various forms of skin disease which may occur in the course of diabetes, Dr. Kaposi mentions asteatosis and anidrosis, pruritus, urticaria, acne cachecticorum, roseola and erythema as the chief functional or nutritive forms of inflammatory eruptions which may be present. The various degrees of eczematous inflammation are very frequently due to the direct irritative influence of diabetic urine, and hence frequently manifest themselves on or about the genital organs, especially in women. The question, however, has been freely discussed, as to whether the irritative effects are not to be attributed to the presence of fungoid growths in the diabetic urine rather than to the grape sugar itself, or even, and this seems the more probable, to the presence of irritative salts of ammonia, the products of chemical decomposition. Paronychia diabetica is a condition not unfrequently met with, but perhaps the most common of the diabetic dermatoses are furunculosis and anthrax. The former especially is recognised by many observers as an early symptom, or even as a forerunner, of the general disease. Carbuncle generally occurs as a late concomitant of furunculosis, and is in some cases a rapidly fatal complication. By some authors it has been assumed to be itself the first indication of the diabetic condition, but this view is combatted by Professor Kaposi, who finds that in almost all the recorded cases no examination of the urine was made before the appearance of the carbuncles. With respect to gangrene, apart from boils and carbuncles, it would appear that its occurrence is rare, but in nearly all the cases on record, the legs and feet seem to have been the parts most affected. In some cases, perhaps, the possibility of gangrene from marasmus or from atheroma of vessels, must be recognised, but the greater number of cases are undoubtedly in direct association with diabetes. None, however, present the peculiar features of serpiginous increase and partial healing, noted in the present case. The presence of grape sugar in the tissues must be regarded as the cause of all these skin affections. Pruritus may be due to direct irritation of cutaneous nerve fibres, although central irritation may also play a part in its production, the nerve control of secretion and of circulation, may in like manner be disturbed, and thus, nutrition be interfered with. The tendency to gangrene, whether it be of the lungs or of the skin, localised or diffused, is a very marked feature in diabetes. Reproduction of tissue also would seem to be generally interfered with in most cases, although instances of papillomatous over-growth of inflamed tissues are not wanting in medical literature; with the description of such a case Dr. Kaposi's address is concluded.

Local Applications in Eczema.—In a lecture on eczema, Dr. Duhring, of Philadelphia (*Medical News*, March 8th), after dwelling on the importance of constitutional treatment in many cases, enumerates the following as the best local applications:—In the *erythematous* variety, usually met with about the face, he recommends carbolic or boracic acid, especially the former, as in this formula: Acid Carb. ʒss, Glycerinæ gtt. xv, Alcohol ʒj, Aquæ ʒiv; also one of calamine and zinc oxide: Calam. Zinci Oxyd. aa, Glycerinæ aa ʒss, Aquæ Calcis ʒiv; and the following Zinci Sulph. Pot. Sulphuret aa ʒss, Aquæ Rosæ ʒiv, twice a day for ten minutes. In the *vesicular* variety, when acute, excellent results follow the use of black wash, followed immediately by oxide of zinc ointment. This is a valuable, mildly stimulating, drying ointment, and is useful, both alone and in combination. Of the various dusting powders, the following is one of the best: Talci Veneti ʒiv, Zinci ox. ʒj, Amyli ʒiii, Salycylic Acid gr. x or xv to the oz. of lard, and oleate of zinc 1 drachm to the oz. does well in some cases; and the above calamine lotion is also valuable. *Papular* eczema, as a rule, requires strong lotions, and that of carbolic acid is one of the best: Acid Carb. ʒiss to ʒiii, Aquæ Oj. Thymol 1 to 3 grs. to the oz. of water may be used, as also liquor picis: Picis Liquidæ ʒij, Pot. Caustic ʒj, Aquæ ʒv. This is to be diluted with water, 1 drachm to 2 or 3 oz. of water. Strong sulphur ointments are sometimes very valuable. In the *pustular* variety ointments of calomel, white precipitate and sulphur, from 1 scruple to 1 drachm to the oz. of lard, may be recommended. In the *squamous* variety, tar is the most valuable remedy, and may be used as the *huile de cade*, 1 or 2 drachms to the oz. of lard, or as tar ointment, or as liquor picis alkalinus as above. Ammoniated mercury, 15 to 60 grains to the oz., is serviceable. When large surfaces are involved, a remedy like tar should be first tried on a small patch, to determine whether it will agree. In *eczema rabrum* of the leg, the rubber bandage may be frequently used with benefit. No one remedy can be positively relied upon to effect a cure in a given case, especially where the lesions are extensive.

Local Treatment of Facial Erysipelas. — Dr. Schallenberger states that for several years he has employed a mixture of salicylic acid, one drachm, glycerine and rose-water of each half an ounce, which he applies by means of a camel's-hair pencil frequently and thoroughly to the affected parts, taking care to cover well beyond the line of demarcation. He has a record of quite a number of cases so treated, and in every instance the first or second application has been sufficient to check the spread of the disease. The only internal treatment was saline water or mixture.—*Philadelphia Medical News*, April 5th.

Scleroderma in the Adult.—Dr. Nicolich, of Trieste, terminates a long article in *Lo Sperimentale* for October with these conclusions: (1) Scleroderma is a special inflammation of the dermis and subcutaneous conjunctival

tissue, which also attacks the mucous membrane of the mouth and of the vagina, and pursues a slow course, commencing with hyperplasia, and terminating with atrophy of the parts attacked. (2) This inflammatory process is in all probability secondary to trophic nervous changes. (3) It may invade the skin of the entire body, but the upper half is most frequently affected. (4) Females are more predisposed to it than males, and it is met with at all ages, but principally between the twentieth and thirtieth year. (5) The most frequent occasional cause is the action of cold on a sweating skin, or simple overheating. (6) The cure of the disease is only possible in its first stage, but material improvement may be obtained in the second stage. (7) "Massage" and electricity are the means from which the best results have been obtained.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 18TH, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

Sequel to a Case of Perichondritis of the Larynx.

THE paper, to which the following is the sequel, was read before the Society by Dr. DE HAVILLAND HALL on April 28th, 1882. The subsequent course of the case showed how untrustworthy negative histories are, as the *post-mortem* revealed marked syphilitic lesion, so that the perichondritis was almost certainly of syphilitic origin. The patient, a man, aged 25, was admitted into Westminster Hospital on October 9th, 1882, wearing a tracheotomy tube, for the purpose of having his stenosed larynx dilated. The day after his admission painful swellings of the joints and in the muscles developed. These disappeared under the use of large doses of iodide of potassium and the inunction of blue ointment, but the pain and febrile disturbance prevented any treatment of the laryngeal stenosis. In the beginning of February, 1883, the patient left the hospital, free from pain but very emaciated. He was then lost sight of till July 2nd, when he was re-admitted into the hospital, suffering from albuminuria and diarrhœa, and he died two days later. The autopsy showed constriction at the junction of the larynx and trachea, the aperture only admitting a No. 12 catheter; above the point of constriction the mucous membrane was normal; below, thickened, of a dark chocolate colour, and its surface bathed by a layer of yellow pus; the right cricoid cartilage was partially absent. The liver was a marked example of the fatty and lardaceous degeneration, and there were peri-hepatic and peri-splenic adhesions.

Schrötter's instruments for dilatation of stricture of the larynx were exhibited.

The PRESIDENT observed that it was frequently concluded that tumours which had become diminished under iodide of potassium were either aneurysmal or syphilitic. Such an inference was, in his opinion, unjustifiable; and in support of his view he quoted a case lately seen in Glasgow, in which severe pain had been relieved, and swelling reduced under iodide, in an ordinary cancerous tumour.

Dr. HALL pointed out that in his case the swelling had been not only reduced but completely removed. No ill effects had followed the passage of the instruments into the larynx.

A Case of Tubercular Tumours of the Larynx.

Dr. PERCY KIDD communicated the following case:—A patient, aged 50, who had suffered from cough, hoarseness, and shortness of breath for eight months, came under observation as an out-patient at the Brompton Hospital in the following condition:—chest, signs of consolidation of the upper part of the left lung, with complete absence of râles; larynx normal, with exception of the vocal cords; on the posterior extremity of the left cord was a spherical tumour, as large as a small pea; on the corresponding part of the right cord there was a small pinkish prominence; the pulmonary condition remained unchanged for months, scanty obscure râles being heard occasionally, but more often were absent. There was very slight increase in size of the laryngeal tumour, but the prominence on the right cord gradually assumed the proportions of a tumour, which, like that on the other cord, resembled a pea in shape and size. There was no further growth of the tumours. Ten weeks after his first visit, the patient was admitted into the hospital in consequence of a spasmodic laryngeal attack in the out-patient room, from which, however, he soon recovered. For the four months he remained in the hospital he had slight spasmodic attacks from time to time, depending upon the varying degree of swelling of the aryepiglottic folds. The tumours remained unaltered, and there was no change in the pulmonary condition. The aortic second sound was noticed to be much accentuated, and occasionally a systolic murmur was heard under the left clavicle, which was thought to be due to aortic dilatation or aneurysm. The patient was discharged after his condition had become stationary, the physical state of his chest and larynx being unaltered. A month later he appeared in the out-patient room with signs of excavation of the left lung, and with much swelling of the aryepiglottic folds, but without any change in the appearance of the tumours. He was re-admitted in a very weak state, and gradually became worse. The laryngeal obstruction increased so much, that tracheotomy had to be performed during a spasmodic attack in order to save his life, but he sank two days later. The *post-mortem* examination revealed pulmonary phthisis of a fibroid type in the left lung, tubercular ulceration of the posterior wall of the larynx and of the trachea, with symmetrical pea-sized tumours situated over both processus vocales; atheroma and dilatation of the aorta; granular contracted kidneys; fatty liver; tubercular ulceration of the colon. A microscopical examination of the tumours showed that they were an outgrowth from the lateral aspect of the inter-arytenoid fold, and consisted of collections of sub-epithelial miliary tubercules, and of a cellular infiltration of the mucosa and submucosa. Tubercle bacilli were found in abundance in the miliary tubercles and in the cell infiltration. In the *Wiener Medicinische Presse*, April, 1883, Schnitzler records a case in which he diagnosed multiple tuberculous tumours of the larynx. The tumours were removed with the guillotine, and proved to consist of aggregations of miliary tubercles. Schnitzler believes that his is the first case in which such tumours have been recognised during life.

The PRESIDENT, commenting upon the difficulties of diagnosis in the case, enquired whether in cases of tubercular disease of the lung, any forms of tumour would be likely to occur in the larynx, other than tubercular.

Dr. PERCY KIDD pointed out that in his case the tumours in the larynx had been present before any evidence of the tubercular disease of the lung could be discovered.

Dr. WHIPHAM referred to a case under his own care, in which there had been enlargement of the left ventricular band and left arytænoid cartilage. No signs of disease in the lungs except slight emphysema. Some improvement followed the use of iodide of potassium, but phthisis subsequently became developed, and death took place from tubercular disease, no signs of syphilis being discovered *post-mortem*.

Dr. DE HAVILLAND HALL thought that it was always important to remember the possible conjunction of tubercular and syphilitic disease in a single case. Dr. Kidd's case was valuable if only from its extreme rarity. It seemed most remarkable that tubercular infiltration should go on without ulceration for nine months in so exposed a part as the processus vocalis.

The PRESIDENT called attention to the possibility of fibroid growth within these tumours, which might have served to check disintegration.

Dr. PERCY KIDD, in reply, expressed regret that no further information had been elicited as to the comparative rarity or otherwise of tubercular tumours of the larynx. Microscopic examination had shown that the tumours were not fibromatous, and the fact of their non-ulceration was difficult to explain. He had seen two cases of somewhat similar kind lately, in one of which ulceration had taken place.

Cases of Excision of the Rectum for Cancer.

Mr. HARRISON CRIPPS read the notes of three cases of cancer of the rectum, in which he had excised the lower part of the bowel, the operations having been performed respectively seventeen months, eighteen months, and four years ago. In the first case, that of a man, aged 68, the symptoms had existed for two years. The disease consisted of a hard, irregular mass on the posterior and right wall of the rectum, about two-thirds of the circumference of the bowel involved, the disease not extending more than two and three-quarters of an inch from the anus. The lower three inches of the bowel were removed, with the exception of about one-fourth of its circumference on the anterior wall. The patient was much troubled during his convalescence from symptoms arising from enlarged prostate, but was discharged in a satisfactory condition, so far as the bowel was concerned. At the end of a twelvemonth his medical attendant wrote that he was alive and comparatively comfortable, no return of the disease could be detected, but he was unable completely to retain his fæces. Mr. Cripps had examined this patient since sending in the paper, and found that he was suffering considerably from prostatic troubles. There was some hardness in this neighbourhood, but no certain symptoms of recurrence. The second case was that of a lady, aged 60. The disease extended all round the bowel on the anterior wall, nearly as high as four inches. Mr. Cripps did not regard the case, from its extent, as a very favourable one for operation, but at the wish of the patient undertook its removal. The bowel had to be dissected for two inches from the peritonæum. The patient made a very satisfactory recovery; she suffered much from contraction, but there was no recurrence for more than a year. The disease then recommenced. The last case was that of a lady, aged 40, who was recommended to the author by Dr. Matthews Duncan. The disease consisted of a hard ulcerated mass, involving one-half the circumference of the bowel to a height of two inches, and filling the ischio-rectal fossa. The disease was removed in July, 1880, and proved, under the microscope, to be a typical example of adenoid cancer. The patient has been frequently examined since. She has completely regained her old strength and health, has no pain or discomfort whatever, and remains, after nearly four years, perfectly free from any symptom of recurrence. Mr. Cripps remarked that he was much indebted to Mr. Butlin for his assistance in the operations performed.

Mr. MORRANT BAKER gave details of three cases of excision of rectum under his care in St. Bartholomew's Hospital. Of these, one died from the after-results of an unavoidable wound of the peritonæum, and two others recovered, but the disease had recurred in one of them after several months' comparative freedom from discomfort. He fully agreed with Mr. Cripps as to the value of the operation, whether for relief or cure.

Mr. WALSHAM referred to three cases upon which he had operated. Of these, one had lived for three months before recurrence, another died in three days, and in the third case only partial removal of the diseased tissue had been possible, but marked relief followed the operation, and the patient had been able to return to work; the disease, however, had lately begun to increase once more. He considered that in all cases of cancer of the rectum, an examination under chloroform should be made before any opinion as to treatment was given. He would prefer to use the scissors rather than the ecraseur in removing the rectum, partly because of the greater ease with which hæmorrhage could be controlled, and partly to avoid the bruising of adjacent tissues which the ecraseur involves. Looking at the success obtained in his own case of partial removal, he threw out the suggestion that removal of a part should be attempted, even in cases where it was not possible to extirpate the whole of the diseased tissue.

Mr. DENT, whilst agreeing in the propriety of the operation in ordinary cases, called especial attention to the condition of incontinence which sometimes followed it, and to the intractable stricture of the anus that occasionally occurred. He believed thal too early interference with a contracting anus, by bougies, was frequently the cause of subsequent incontinence. He thought that some means might be devised to remedy both evils, and appealed to Mr. Cripps for suggestions upon these points.

Mr. BARKER had removed the lower part of the rectum in an old man. The case did very well, no attempt being made to dilate the stricture of the anus which followed. Incontinence of fæces was only observed when the motions were loose. In this case, however, a small portion of mucous membrane remained intact anteriorly, the bowel had contracted from behind forwards, and a kind of valve had been formed, which permitted the passage of the descending fæces, whilst it prevented the entrance of the ascending finger. Such a case would not have been benefited by bougies.

Mr. GODLEE mentioned a case, in which he had removed a portion of the rectum for cancer, using Paquelin's cautery. Contraction followed, with incontinence, and both conditions had been somewhat improved by dilatation. He was inclined to agree with Mr. Walsham, that partial removal might give relief, and he referred to a case where periodic scraping of an epitheliomatous tumour in the rectum had served to keep the disease in check.

The PRESIDENT thought that the discussion had shown that whilst excision of the rectum served to give relief for a time, it did not tend to prolong life. He mentioned one case in which he had diagnosed cancer six years before the patient's death. He considered that the limit of eighteen months, so frequently laid down in books, was not in accordance with general experience, and asked Mr. Cripps' opinion upon this point.

Mr. CRIPPS, in reply, stated that he had never seen any case which had lasted so long as six years. In his own experience, one year, or at most eighteen months, was the ordinary limit of life in rectal cancer. That in some cases the operation had served to prolong life far beyond this limit, there was abundant evidence. In one of his own cases, operated on in the Great Northern Hospital eight years ago, no recurrence of the disease had as yet taken place. He agreed with Mr. Walsham as to the use of the scissors in preference to the ecraseur. He would hesitate to operate in any case in which he was unable to pass his finger beyond the upper margin of the diseased tissue. Freedom from adhesions to surrounding tissues was essential in order to ensure complete removal. He thought that incontinence was in reality less troublesome than is usually supposed. Contraction, however, was more serious, and he would endeavour to prevent its occurrence by allowing the wound to heal over a bougie. As a remedy, he would suggest either colotomy, or extremely free posterior division of the strictured tissue.

A remarkable Case of Tubercular Meningitis.

Dr. ANGEL MONEY communicated the following case:—The patient was a female infant, aged 9 months, when first seen on December 7th, 1883. It appeared that the child had enjoyed good health till about five months pre-

viously, when it had the measles, but apparently recovered completely in a short space of time. On November 27th the child had a fit, shortly after which the left arm and leg were found to be completely paralysed. The intelligence was, so far as could be judged, unaffected. The corporeal state was decidedly one of great fatness. The condition of hemiplegia seemed to be slowly passing away, until December 27th, when a series of fits set in, unconsciousness supervened, and the patient died on January 2nd. On January 1st there was hurried and somewhat Cheyne-Stokes breathing; the pulse was regular, 96, but no fever. The temperature on the morning before death, however, was taken in the rectum and found to be 107°. At the autopsy the brain was soft and pale, with considerable excess of pale clear fluid in the lateral and fourth ventricles, but without glueing of the cerebellum to the posterior boundaries of the last-named ventricle. There were signs of not recent meningitis, chiefly at the base, and a large branch of the right middle cerebral was found to be thrombosed. The other organs showed signs of tuberculosis. A minute vegetation existed on the smaller flap of the mitral valve. In his remarks on the case, Dr. Angel Money pointed out the difficulties of diagnosis. He said that in children the symptoms and signs of disease were singularly wanting, especially when we had to do the brain. A mass of disorganisation in a child would produce much fewer signs than an equal amount of damage in adult, and this was still more the case the younger the child.

Dr. O'Connor enquired as to the stage of dentition in the case, and mentioned an instance of temporary hemiplegia, referable to delayed dentition.

Dr. Glover related a case in which marked hemiplegia had entirely disappeared within a few minutes of its occurrence, similarly short hemiplegic attacks following one another at intervals for a few days. Vertigo and, latterly, headache and disordered vision had been the only sequelæ as yet. There was no evidence of renal disease.

Dr. Tonge Smith mentioned a case in which sudden hemiplegia had occurred and passed off within a few days, the patient subsequently dying from tubercular meningitis.

Dr. Heron gave some interesting details of a case of evanescent facial paralysis in a gentleman engaged in active business, who died on the following day from cerebral hæmorrhage.

Dr. Money, in reply, explained that in his case the paralysis had not been evanescent, but had simply been less marked. The child had two lower incisor teeth.

The following living specimens were exhibited :—Vascular tumour of neck, by Mr. Bellamy; recurrent naso-pharyngeal growth, by Dr. Stonham; and a case of congenital hypertrophy of one limb in an infant.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, April 22nd, 1884.

Dr. George Johnson, F.R.S., President, in the Chair.

An Enquiry into the Cause of the Increase of Cancer in England and Wales.

By F. B. Jessett, F.R.C.S., Surgeon to the Royal General Dispensary.

The author regarded the increased death-rate from cancer, to which attention has been drawn by the Registrar-General in his last annual report, as signifying a positive increase in the prevalence of cancer, rather than as being open to explanation on the ground of greater accuracy of diagnosis, as suggested in the report. On examination of the statistics, for ten years the increase is found to be from 9·945 deaths registered in 1872 to 13·542 deaths in 1881, or, taking the death-rate, from 431 per 1,000,000 in 1872 to 520 in 1881. On analysis of the Registrar's returns for the different counties, the death-rate from cancer in the Fen districts was seen to be much higher than elsewhere, with the exception of London, Devon, Somerset, Gloucester, and North Wales; which places the author would exclude from account on special grounds. Cancer was more rife in low-lying, damp situations; but heredity, increased by intermarriage, had probably much to say to its prevalence in the "cancer district," the Fen counties above alluded to. The increasing mental strain in the struggle for existence might tend to account for the increased development of cancer among persons predisposed, and these points would have to be borne in mind in advising those predisposed to the disease.

Dr. Snow thought the statistics quoted were somewhat vitiated by the fact that all forms of cancer had been grouped together; while it was well known that the epithelial variety was due entirely to local influences, differing in this respect widely from scirrhus and sarcoma. He himself had advocated a neurotic origin, and, in doing so, had only followed Sir James Paget's teaching. As a careful enquirer into this mode of causation, he had come to the conclusion that it really existed, and was well worthy the attention of the medical profession. Among the poor, who were subject to great mental worry throughout life, it was somewhat difficult to get reliable statistics; but such liability to error did not exist in statistics drawn from observations made in good society, and when a tumour developed immediately after some family catastrophy he thought it only natural to set it down as the result of the nervous shock. In families in which there was already a predisposition to cancer, the various members lived in constant dread of an outbreak of the disease in themselves.

Mr. Harrison Cripps remarked that he listened with great interest to Mr. Jessett's paper, for he had previously made investigations in the same direction, the results of which had been published partly in the Jacksonian Prize Essay and partly in the St. Bartholomew's Hospital Reports for 1878. He had taken the twenty-five years from 1851 to 1876, and had found, according to the Registrar-General's returns, that the death-rate from cancer had steadily increased during that period, so that in the latter year it was more than 30 per cent. higher than the former. However, on further investigation he came to the conclusion that these statistics were misguiding, at least to some extent, partly owing to the system of registration being frequently changed, as to what was included under the term cancer, and partly to an improved diagnosis. Mr. Cripps stated that even the increased prevalence of cancer in certain districts required to be very carefully considered in detail. For instance, the general cancer mortality of London appeared high, but here it was found that the deaths from cancer were nearly double in some parishes to what they were in others. As regards Mr. Jessett's remarks as to the increased frequency of cancer mortality in wet years, a moment's consideration would show that this could have nothing to do with the cause of the disease; for, from cancer being a chronic disorder, it would be extremely improbable that a patient would both catch the disease and die of it the same year. Nor could he agree with the author of the paper, that increased worry and strain, owing to educational pressure, had anything to do with the development of cancer; for the great majority of cases were in-patients over 40 years of age, and who had, therefore, escaped any influence of the Educational Acts. If it could be shown that any particular class, such as the professional or business classes, suffered from cancer in excess of the general population, it might afford some evidence to support Mr. Jessett's views, but at present there was no evidence of the kind forthcoming. As to inheritance, Mr. Cripps disbelieved in the whole doctrine. The evidence upon which it was founded might be considered under two headings :—First, That it is a matter of notoriety that cancer runs in certain families. Secondly, Evidence founded upon certain statistical facts. As regards the first kind of evidence it was wholly inadmissible from

a scientific point of view without the positive facts upon which it was based. Of course from time to time isolated instances would occur of more than an average amount of cancer in a particular family. As to statistics, the most reliable were those published by Mr. Baker, of cases occurring in the practice of Sir James Paget. According to these tables, the whole number of cases of cancer in which the family history was investigated must have been 460. Aunts, uncles, cousins, in fact all relations except the immediate parents were excluded, for the impossibility of knowing the number of these distant relations rendered them useless in forming a table of comparison between a cancerous and a non-cancerous family. So, also, as regards the grand-parents for individuals especially of the hospital class one could seldom accurately assign the cause of death in their grand-parents. The cause of death in the parents was commonly known, therefore the relative frequency with which malignant disease was found in the direct offspring of cancerous parents admitted of comparison with the offspring of the non-cancerous. In Sir James Paget's tables the proportion of the parent of cancerous patients affected with the same disease was 1 in 25. Mr. Cripps having carefully worked out tables from the cases admitted into St. Bartholomew's during the last ten years, arrived at figures closely tallying with Sir James Paget's; finding that of the parents of the cancerous patients in the hospital 1 in 28 had been similarly affected. These statistics merely proved that 1 in 26·5 of the parents of the cancerous were affected. What was necessary, was to compare this proportion with the death-rate amongst the parents of the non-cancerous or general population. It would not be right in this calculation, simply to take the whole number of deaths in the community, and find out how many of the deaths were due to cancer, for the parents of cancerous patients would certainly have been adults at the time of their deaths. The proportion of persons who both became parents and died below the age of twenty was so small a percentage, that it could fairly be ignored. In the ten years, 1861 to 1870, 2,379,622 deaths occurred in England and Wales above the age of twenty years, 81,699 of these were from cancer, or 1 in 29. Thus, then, amongst the parents of cancerous patients the death-rate amounted, according to Sir James Paget, 1 in 25; according to St. Bartholomew's Register, 1 in 28; amongst the whole community above twenty years of age, 1 in 29. The relative frequency of cancer in these two sets of cases differed so slightly that it might well be regarded as accidental, in which case the figures showed that cancer in the parent did not increase the liability of the offspring to suffer from the same disease.

Epiphysitis.

Mr. Macnamara read a paper entitled "Epiphysitis," under which term he included *diffuse ostitis of children, osteo-myelitis during period of growth, suppurative periostitis, and acute necrosis.* This disease, fully described by M. Gosselin in the *Archives Générales de Médecin* for 1858, hardly recognised by English authorities, seemed to exist independently of acute osteo-myelitis. In this paper epiphysitis of the tibia was alone referred to, and the author brought forward five cases of the disease in that bone, illustrating the various phases of the disease, and showing that it might run its course (*a*) without affecting either the ankle or knee-joint; (*b*) that it might give rise—1. To necrosis of the entire diaphysis; 2. To abscess of the bone; 3. To diffuse sclerosis and enlargement of the tibia. The disease consisted in inflammation commencing at the line of junction of the diaphysis and epiphyseal cartilage. From this line the inflammatory action extended along the soft structures contained in the cancellated tissue and Haversian system of the diaphysis, involving the contents of the medullary canal and the deep layers of the periosteum. In many cases the inflammatory action quickly led to suppuration or to necrosis of the diaphysis; the diaphysis of the bone might thus be entirely destroyed without the epiphysis and neighbouring joints being affected. If arthritis occured it was a secondary affection. Epiphysitis did not always lead to necrosis of the diaphysis. Early treatment often saved the bone, and the active changes in the bone might subside. If abscesses formed in the cancellated tissue of the bone, the surrounding osseous tissue underwent a condensing ostitis. In other cases the inflamed diaphysis became simply sclerosed with increased periosteal growth. *Symptoms.*—Two of the five cases brought forward were at first mistaken for articular rheumatism. The disease commenced with great pain and swelling in the proximity of a joint and general pyrexia. The limb became much swollen and of a brawny hardness, abscesses formed, and in many cases the necrosed diaphysis could be felt. Symptoms of scpticæmia often followed. In other cases the disease subsided, and ultimately signs of local abscess or of diffuse sclerosis manifested themselves. *Treatment.*—In the early stages of the disease, free incision down to the extremity of the affected diaphysis, and drainage of the part. In severe cases, trephining the bone at one or more places. When the greater part of the diaphysis was necrosed it must be removed, dissecting the periosteum from it. A new tibia often formed. If the tibia did not re-form, the fibula increased in size, and with proper appliances formed a very serviceable limb.

Mr. Holmes, while expressing great interest in the cases related, dissented entirely from the conclusions arrived at. Why was the term epiphysitis suggested for a disease in which the epiphysis appeared to be quite unaffected? The diseases which had been described in the paper were not by any means confined to childhood. Besides Gosselin, Chassaignac had also very accurately described these changes under the term acute periosteal abscess, a description which he (Mr. Holmes) many years ago had amplified and published, and which was one of the first adequate descriptions given in the English language. It was a better name—even if not the best—than epiphysitis, for an affection which often involved all the bone, except the epiphysis. Mr. Thomas Smith had carefully described the affection of the epiphyses, under the term acute arthritis of infants, and it was quite different from Mr. Macnamara's. The cases described to-night were well recognised by English surgeons; in a majority they were cases of acute periostitis; and in a minority, cases of osteo-myelitis. The disease commonly commenced at some distance from the epiphysis, in the subperiosteal tissue. Mr. Macnamara had further mixed up cases of chronic abscess of bone, first described by Brodie; this often resulted from a contusion or other local injury, and had nothing whatever to do with the epiphysis. He doubted whether it was good practice in the acute cases to trephine at first; he preferred to cut down through the periosteum, thus relieving tension and giving exit to exudations. Cases of osteo-myelitis were not infrequently secondary to the sub-periosteal disease, and he related a case in point; in such cases trephining was not called for, if suitable previous treatment was adopted.

Mr. Barwell said he agreed with Mr. Holmes that a mistake had been made in calling the cases epiphysitis; had there been epiphysitis, the sequel would have been quite different. As to the practice of trephining, raised by Mr. Holmes, he thought it useful in a certain number of cases, in those in fact in which the disease commenced in the medullary cavity, he had found much benefit result afterwards, for it let out the oil and pus contained within the cavity. In other cases the disease began in the periosteum, and trephining was less useful. He thought Mr. Macnamara had hardly done justice to the work of English surgeons on this subject; he had himself, as far back as 1862, given a tolerably accurate description of epiphysitis, apart from disease in the shaft, as well as of disease of the shaft, and he had shown at the sister societies specimens of the diaphysis of long bones which he had removed on account of disease.

Mr. Thomas Smith said that Mr. Holmes had so fully

expressed views with which he entirely concurred, that it would only be necessary for him now to say very little. He was grieved to find that Mr. Macnamara under such a term had swept together so many diseases which were distinct. And, as regarded descriptions of the disease, besides his own on acute arthritis in infants, Mr. Holmes and Mr. Morrant Baker in this country had both contributed important papers on its different phases. He enquired whether in the cases related by Mr. Macnamara there were any secondary affections of other joints or of the pericardium; frequently he had had to decide on treatment in cases in which the constitutional symptoms were very severe. He remarked that all denuded bone did not necessarily die, if time were given, and besides the objection that the bone was not always reproduced, there was the further disadvantage that the skin of the shin became adherent to the resulting cicatrix even when it was reproduced, and this cicatrix was very apt to ulcerate.

Mr. GANT especially desired to call attention to the want of correlation between the pathology, symptoms and treatment in the cases brought forward. Otherwise the facts were interesting, though not new.

Mr. MACNAMARA replied he would forego the term epiphysitis, as the Fellows seemed to think it objectionable or inadequate; but he supported his previous contention, that the disease in his cases had commenced at the line of junction between the shaft and epiphysis, and had thence spread and finally involved the shaft.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 2ND, 1884.

H. GERVIS, M.D., F.R.C.P., President, in the Chair.

DR. F. NEUGEBAUER, jun., showed specimens and photographs illustrating the production of spondylolisthesis, and presented books on the subject. His remarks have already appeared in the *Annales de Gynécologie*, February, 1884.

Remarks were made by the PRESIDENT, Dr. BARNES, and Mr. W. ADAM. The specimens were referred to a subcommittee.

The PRESIDENT proposed that letters of condolence be sent from the Society to Her Majesty the Queen and H.R.H. the Duchess of Albany on the sad occasion of the death of H.R.H. the Duke of Albany. This was unanimously agreed to, and the President undertook to write the letters.

Dr. CARTER showed two dermoid cysts removed after the death of a single woman, aged 50; one of the cysts being also cancerous.

Mr. THORNTON made remarks.

THE RELATION OF PROLAPSE OF THE VAGINA TO HERNIA.

Mr. DORAN read a paper on the "Relations of Prolapse of the Vagina to Hernia," illustrated by two pedigrees. The paper described cases of women affected with prolapse of the anterior wall of the vagina, where a very marked family history of hernia existed. The genealogies of the patients were given in a tabular form. The cases all tend to prove the close relation between hernia of the intestine and displacements of the female pelvic viscera.

Dr. MATTHEWS DUNCAN had long taught that intestinal hernia and procidentia uteri were alternative conditions. The whole of Mr. Doran's excellent paper was a part of the great subject of the retentive power of the abdomen or its pressure relations.

Dr. CHAMPNEYS said that in the work of Landen, on movable kidney, various associated conditions were mentioned; hernia was found in 7 per cent., descent of the uterus or vagina in 13 per cent., "retroflexion" in 15 per cent., and pendulous belly in 25 per cent. No explanation was given of the term "retroflexion," but it probably meant the condition known as "retroflexion" with descent (or rather descent with retroflexion). It was his habit to enquire of patients suffering from descent of the pelvic organs, as to family histories of hernia, prolapsus uteri and prolapsus ani. One such history was the following:—A woman, aged 52, had had procidentia since the age of 27, her eldest daughter (aged 30) has had procidentia since the age of 21; all her three sons had prolapsus ani as children.

Dr. HORROCKS said allowance must be made for the fact, that in the same family it often happened that circumstances obliged all the members to do hard work.

Mr. DORAN, in reply, said that the history of rupture was often difficult to obtain, as the condition was naturally concealed, especially between the different sexes, and also between those of very different ages. In some cases the bladder was not displaced in descent of the vagina and uterus. He had recently seen a case of apparent cystocele, in which no part of the bladder was prolapsed. The distinction between prolapse of the generative organs, with and without cystocele, was an interesting question to solve in relation to hernia.

THE USE OF THE INDUCED CURRENT DURING PARTURITION.

Dr. KILNER read a paper on the "Use of the Induced Current during Parturition." The effects of the current were the relief of pain, prevention of fatigue and *post-partum* hæmorrhage, equalisation of the pulse, increase in frequency and strength of the uterine contractions, and the prevention of vomiting. The pain from stretching of the vulva was, however, not alleviated by it, nor did it to any extent relieve pain in cases of instrumental labour. The author now employed the coil (shown) in nearly all cases. In about three hundred cases, *post-partum* hæmorrhage only occurred twice. The coil sometimes failed to increase uterine contractions when most needed. After its use for an hour or an hour and a half, it exercised its sedative action, and no longer increased the contractions. In some cases it produced violent and almost continuous contractions. In one case a contraction lasted fifteen minutes. No prognosis with regard to these points could be made. It had no effect in diminishing afterpains. It generally prevented or stopped vomiting. Statistics were given and directions for use.

The PRESIDENT said that an agent which increased uterine action while lessening pain was almost too good to be true, but labouring women would be grateful for such a method.

Dr. PLAYFAIR had tried the current, and it had proved a failure, perhaps from want of special skill; but if special skill were needed it could not be generally used. Its effects in diminishing pain were slight, and not to be compared with other means at our disposal. A battery was a cumbrous thing to carry about, and was likely to alarm patients; as an oxytocic he had found it useless. Dr. Kilner compared its action with that of ergot, which should never be used to accelerate delivery. Uterine manual pressure was the best and safest oxytocic.

Dr. WALTER had used the current for more than seven years for inertia of the uterus after the expulsion of the placenta, and found it in some cases superior to ordinary means. He had found it useful in *post-partum* hæmorrhage.

Dr. HORROCKS asked for details as to live birth, suspended animation, hæmorrhage, and whether premature labour had been reduced. In this respect electricity had always hitherto failed.

Dr. ROUTH had found the electrical current useful in migraine; in lumbago a man would walk into his study, walking like an old person, and would leave as erect as a soldier. He had also dispersed uterine fibroids by its frequent use, and tumours of the breast.

Dr. MURRAY thought that if the electric current had such power as had been described, the possibility of rupture of the uterus would have to be remembered. He had used it for hæmorrhage, but considered its value very doubtful.

Dr. KILNER replied that, as regards the lessening of pain, the current was more under control than an anæsthetic, and never caused sickness. He had never seen a case of rupture of the uterus.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FRIDAY, APRIL 18TH, 1884.

Dr. DUDFIELD, President, in the Chair.

Outbreak of Small-pox in East and North London.

A PAPER on this subject was contributed by Dr. TRIPE, medical officer of health for Hackney. The prevalence of small-pox during the latter half of 1883, especially in the vicinity of the Homerton Hospital, Dr. Tripe attributed to the contact of the workmen engaged in altering the drains of the building, with the convalescents, although he was not aware of any cases having occurred among the men themselves. But the present epidemic commenced with the appearance of fifteen cases on February 22nd, of which eleven were removed to the hospital. These cases occurred in nine houses, five of them in one house in which there had been one a fortnight previously. Other cases appeared in March in Upton House reformatory for boys, and the Female Refuge in Dalston Lane, the sources of which could not be traced, though the dates March 2nd and 15th were suggestive of consecutive infections. Dr. Tripe exhibited a map showing, by coloured spots, the succession and distribution of all cases which came to his knowledge, from which it appeared that there were within the ¼ mile, ½ mile, 1 mile radii, and beyond this respectively on the first day of the actual epidemic 4, 1, 2, and 2 houses attacked; on the second day, 1, 5, 2, and 3; on the third and fourth days, 4, 5, 7, and 5; on the fifth and sixth, 8, 4, 3, and 4, making in all 20, 15, 16, and 14 in the several areas, the populations of which may be roughly estimated at 10,000, 30,000, 60,000, and 100,000 respectively, which gives an average of 2, 0·5, 0·24, and 0·0014 per 1000 population in each. Outside the mile these numbers are, however, not even approximate, as excepting in the immediate vicinity of the hospital, Dr. Tripe had no information of cases other than those removed to the hospitals of the Asylums Board, or through applications for disinfectants, &c. The admissions from the several parishes in the weeks ending March 6th, 13th, 20th, and 27th, were from Hackney, 10, 5, 2, and 72; Islington, 6, 1, 4, and 14; Bethnal Green, 3, 1, 2, 15; and Shoreditch, 1, 5, 7, 9. Besides these Hackney alone has sent 20 cases in the week ending April 3rd. It appeared from the reports of the Asylums Board that during March 191 cases were removed to one or other of their hospitals, of these 89 were from Hackney, and 79 from the other three parishes above named, 33 being from Islington, and 23 each from Bethnal Green and Shoreditch, leaving 13 only for the rest of London. The population of the three parishes was about three times that of Hackney, which, therefore, had suffered three and a half times as heavily as they, the greatest incidence falling on the district immediately surrounding the hospital, although it contained a smaller number of patients than usual when the outbreak took place, and only half what it had a month before. Neither the direction of the prevalent winds, nor the route taken by the ambulances, nor the removal of convalescents to the Atlas, could be made to explain this, for the patients were transferred on February 5th, and no case was taken in between February 15th and the date in question. Still less did a comparison of the meteorological phenomena of this period with those of former epidemics throw any light on its causation. Lastly, in many cases no direct communication could be proved between the persons successively attacked. But the fact remained that before the opening of the hospital the distribution of the disease was very different from what it had been since, and the population of the district where it now stood, though much the same as at present, showed no special liability to small-pox. The hospital, which Dr. Tripe had always maintained was not arranged or conducted with sufficient care, was certainly connected with the local incidence of the disease, but for its further distribution in that and other parishes of the East End of London, it seemed we must fall back on aërial transmission, or some agencies still undiscovered.

Dr. DUDFIELD observed that the Kensington epidemic, enquired into by Mr. Power on behalf of the Local Government Board, though in like manner traceable to the proximity of the Fulham Hospital, did not follow the course of the prevailing winds.

Mr. WYNTER BLYTH remarked that streets often produced eddies in very different directions from that of the actual wind.

LIVERPOOL MEDICAL INSTITUTION.

THURSDAY, APRIL 17TH, 1884.

DISCUSSION ON PNEUMONIA.

(*Adjourned from March 27th.*)

THIS discussion followed on a paper by Dr. Caton, entitled "Notes of eighty-four Cases of Acute Pneumonia and Pleuro-Pneumonia, with some Remarks on Septic Pneumonia." After some general introductory remarks on the pathology of the disease, historical evidence was brought forward of the probable existence of an epidemic form of pneumonia. Fatal epidemics of that disease, occurring especially in Iceland, were referred to. In Liverpool, in 1879 and 1881, many cases of a very fatal form of pleuro-pneumonia came under Dr. Caton's care in the Northern Hospital. An examination of the reports of the Medical Officer of Health showed that in those years all the Liverpool hospitals showed a large mortality from pneumonia or pleuro-pneumonia, thus adding additional support to the occasional epidemic nature of this disease in other countries. The pneumonia micrococcus was next described and drawings of it exhibited, followed by a *resumé* of our present knowledge on the subject derived from cultivation experiments. In this respect the pneumonia micrococcus stood in very nearly the same position as the phthisis germ. From February, 1877, to February, 1884, Dr. Caton had under his care at the Northern Hospital 84 cases of pneumonia or pleuro-pneumonia, of whom 29 died, a mortality that surprised him when he first reckoned up his cases. It was explained by the fatal nature of the epidemic variety already referred to, by the habits and occupations of the patients by delay in putting themselves under treatment, and in many cases by complications that rendered recovery almost impossible. Treatment consisted in surrounding the patients with a proper temperature, in the careful application of jacket poultices, and in the administration of carbonate of ammonia and other stimulants, according to the exigencies of the case. He rarely employed antimony or depletion of any kind. Quinine, aconite, bleeding, leeching, croton, and iodine liniments were occasionally employed.

Dr. J. CAMERON expressed his satisfaction at hearing the paper, and at the treatment of its subject. He did not think that sufficient evidence had been brought forward to connect pneumonia with micro-organisms, as effect ought to be connected with cause; nor could he remember a single instance where the disease could be traced to infection. The apparent epidemic variety could be explained by accompanying diseases that left pneumonia in their train. In 1847, influenza followed by pneumonia was prevalent. In Iceland, epidemics of influenza were frequent. The influence of seasons in producing pneumonia must not be ignored, and the mortality depended to a great extent on the age of the patient, his state of constitution, habits, and the time he came under treatment. Immersion during drink was the cause of a very fatal kind of pneumonia. These cases came into hospital very early, and the onset of the disease could be recognised by a feebleness of respiration that preceded the earliest stage of the disease mentioned in books. As to treatment, there was not a *single remedy* for the disease: we could not cure, we could only help. He would not begin with carbonate of pneumonia and brandy; tartar emetic was useful in the early stages. He remembered when frequent bleedings were the rule, and, wonderful to relate, many patients then recovered. Bleeding sometimes did good, but the same physical influence might be obtained by other means.

Dr. WILLIAMS sympathised with Dr. Caton in regard to his large mortality. Since 1878 he had treated 72 cases in the Royal Southern Hospital, with a mortality of 29. His periods of greatest mortality did not coincide with those of

Dr. Caton, and in consequence, did not support the theory of the epidemic nature of the disease. Ten of his cases died in less than three days after admission, one had gangrene of lungs, one had Bright's disease. Four were over 60 years of age, five over 50, and nine over 40 years of age. His treatment consisted in placing the patient in an equable temperature, and in administering ammonia. Antimony was rarely used, and brandy and eggs were given as the pulse became soft.

Dr. Bostock brought forward a case where a healthy child caught pneumonia from the effect of bad hygienic conditions. It lived in a small house surrounded by a cesspool that opened into a sink inside the house. Five other children were successively attacked by the same disease, their illnesses beginning with rigors. He would like an explanation of the theory that there were two kinds of pneumonia, one produced by contagion as the cases just narrated by him, and another produced by cold as after immersion, and where no bacteria were supposed to be present.

Dr. Wm. Carter said pneumonia in hospitals was very fatal, especially in seaport towns. In private practice it could not be called a fatal disease. To occupation, habits, and antecedent ill-health, were to be ascribed the greater hospital mortality over that of practice. Since 1876 he had attended ninety-nine cases of pneumonia in the Royal Southern Hospital. Forty-seven were sailors, the others labourers, &c.; twenty-three died only two hours after admission, one from meningitis, two had secondary pneumonia after typhoid fever, some had Bright's disease, and one had a tumour of the brain. As indications of danger he mentioned especially a fall in temperature and a rise in pulse, and late delirium which was best treated by quinine. He recognised a septic pneumonia set up by wounds, but ordinary pneumonia was not, he thought, an infective disease, or it did not appear to him to be communicable, it often affected only a small portion of the lung, occurred twice, and set in suddenly. As to 1879, he read an extract from a meteorological report of that year, showing the exceptionally low temperature that then prevailed, whilst fogs and rain alternated with 119 days of snow.

Dr. Archer said that of five cases marked temperate in Dr. Caton's tables, only one died; of eight marked intemperate, five died. Climate had more to do with pneumonia than micrococci. In regard to the latter, he thought the profession were going mad. He noticed pericarditis in two cases of left-sided pleuro-pneumonia in Dr. Caton's table, and that quite agreed with his own experience, that pericarditis most frequently followed left pleuro-pneumonia.

Dr. Robertson was astonished at the enormous number of fatal cases of pneumonia reported annually from the workhouse hospital, all of which were under his supervision. It was difficult in a large workhouse hospital to keep such complete records of disease as were kept in the Northern Hospital. He had, however, analysed the cases reported for 1881. Many of them were cases of broncho-pneumonia or typhus, others were cases of pneumonia after whooping-cough, whilst a considerable number belonged to the category of congestion of the lungs in old people. He could not remember any cases of infection in pneumonia, and had not much faith in organisms which were, he thought, often the results of decomposition. His treatment was similar to that of Dr. Caton. Limited bloodletting in selected cases, when there was a full and bounding pulse, with insomnia often acted like a charm. One case of double pneumonia—dying from collapse, pulseless, and livid in the face—was bled to fourteen ounces. In half-an-hour he fell asleep, and made an excellent recovery. An old woman in the infirm wards, caught pneumonia from a sudden chill. She was bled to fourteen ounces, and made a good recovery. He was led to practise blood-letting from watching the effects of the catamenial flow, and of hæmorrhage from the bowels and fever.

Dr. Bare did not look upon pneumonia as a specific disease. In many cases it was produced simply by a chill. He agreed with Dr. Robertson as to the efficacy of bloodletting; but, as a general rule, it should be performed before the third day. Antimony and citrate of potash were much used by him in the early stage, and were very useful. When the pulse became dicrotic, quinine was the best remedy, and sometimes he gave 40 grains per diem. Carbonate ammonia was useful in the later stages, as were atropia and digitalis. That each patient should have two thousand cubic feet of space was a most important item in the treatment of pneumonia.

Mr. R. Hamilton desired to bring back the discussion from the subject of treatment to that of ætiology. He believed pneumonia had a septic origin, and the cases where immersion produced pneumonia, he would explain by the chill of immersion bringing about a degree of temperature and moisture suitable for the reproduction of pneumonia germs.

Dr. A. Davidson said the question was whether pneumonia was the result of irritation or infection. Bronchitis was a disease produced by irritation, lasting a variable time. Pneumonia ended suddenly in a crisis, and belonged, he thought, to the *infective*, not to the *infectious* class.

Dr. Worral thought blood-letting might be usefully employed at a later stage when the heart was weak.

Dr. George Taylor reported a case where a patient of his went to live in London, and became ill with pneumonia. A sister went up to nurse him and took the disease, and so did another sister who followed, and they all died. Sometime after another person went to the same house, and he suffered severely from sore throat.

Dr. Caton, in reply, said he was not a decided believer in the contagiousness of phthisis, but he thought the evidence was in favour of its bacterial origin. In cattle there seemed to be two kinds of pleuro-pneumonia, and he did not see why there should not also be two kinds in man. Pericarditis most frequently followed left pleuro-pneumonia, which was to be expected, as the disease spread through the lymphatics. He agreed with Drs. Barr and Robertson as to the effects of early bleeding, with Dr. Barr as to the necessity of cubic space in the treatment of the disease, and with Dr. Hamilton that chilling may put the organism in a good position for growth.

GENERAL CORRESPONDENCE.

THE PSYCHICAL RESEARCH SOCIETY AND "CLAIRVOYANCE."

[To the Editor of the Medical Times.]

Sir,—It appears from Mr. Gurney's letter of April 13th that he and I are at one in the opinion that none of the methods of blindfolding the alleged "clairvoyant" practised by the Psychical Research Committee, were sufficient to occlude vision, although we may have arrived at that opinion by different routes. This being the case, *cadit quæstio*. I nevertheless ask permission to make a few remarks on Mr. Gurney's letter.

I commended no particular *method* of blindfolding as trustworthy, in my letter to you, nor did I make mention of either "pennies" or "plaster" on the eyes. My statement was, that on a given occasion the subject in question was able to name cards when apparently blindfolded by the Committee, but failed *entirely* to do so when his eyes were covered with cotton-wool by a certain medical observer. That assertion is not challenged by Mr. Gurney; and his statement that on other occasions the cotton-wool method failed to occlude vision is clearly beside the question.

It is easy to apparently blindfold any one, with or without plaster, pennies, or even cotton-wool; it is not very difficult to apply a real blindfold by means of cotton-wool, as was done by the gentleman referred to in my previous letter. It is, moreover, well-known among professional conjurers that cotton-wool or some similar substance properly applied is a perfectly, and perhaps the sole, efficacious blindfold. Plaster and pennies may be quite discarded. Notwithstanding, therefore, Mr. Gurney's apparent implication that no one can be really blindfolded at all, I mantain that on the occasion alluded to the test was satisfactory.

Mr. Gurney's own admission of the untrustworthiness

of all the methods of blindfolding mentioned, as tests of absolute occlusion of vision, fully justifies my charge of untrustworthiness against the special methods employed by the Committee, whatever the conclusions arrived at by the Committee may be. The only trustworthy blindfold in alleged "clairvoyance" is obviously one which effectually bars all power of vision. Mr. Gurney acknowledges that the Committee's tests may have failed to do this; and I assert that on a given occasion a blindfold was applied by an outsider which did effectually bar all power of vision, or, what to the un-psychical researcher at least is the same thing,was followed by the subject's failure to name the cards at all. I would remind your readers of another occasion mentioned in your columns, when several scientific observers came to a definite conclusion as to the nature of the experiments they observed at the Society's meetings. Those who bear in mind also the somewhat remarkable facts that the above-mentioned experiments in clairvoyance were carried on with paid subjects and playing cards will probably acquit me of undue rashness in my criticism of the psychical enquiries. Judging, indeed, from the hitherto published manifestoes of this Society in its own "Proceedings," and in lectures and magazine articles, it is not even rash to say that it betrays a belief in a general disorder of Nature, and that its final cause is apparently the affirmation of the inexplicable.

Mr. Gurney remarks in conclusion that my comment on this *séance* makes it difficult to again invite the gentleman who blindfolded the subject. It is difficult here to follow Mr. Gurney's meaning. In any really scientific enquiry such a comment, if it have any influence at all, should obviously encourage rather than prevent the presence of both sceptical and unbelieving outsiders when experiments are being made. The serious pursuit of truth can never be hindered by any criticism, however free.

I am, Sir, yours, &c.,

April 21st, 1884. H. B. DONKIN.

EXAMINATION FEES FOR UNIVERSITY UNDER-GRADUATES UNDER THE MEDICAL BILL.

[To the Editor of the Medical Times.]

SIR,—Your editorial note on this subject proceeds upon a complete misapprehension of the provisions of the Bill. The clause dealing with this point declares that University under-graduates shall pay for their State examination only the cost of the examination, while other students shall pay an additional sum, which is to be appropriated to the maintenance of the museums, libraries, and other educational appliances of the Colleges. The principle of this clause is, that a University student, having paid in money for the use of University museums, &c., and having paid in brain-work for the academic study and discipline of a University, should not be required to pay also for the College museums and libraries which he has not used. This is just and rational, and every College is willing that University students who have done this, should be admitted to the State examination on payment of its cost. But, Sir, the question is, what is a University? And what is an under-graduate? The Universities which are in the public mind, when they consider this subject, are Oxford, Cambridge, and Dublin, where a student resides for four years at his place of study, is instructed by the teachers provided by the University, and with the aid of the educational paraphernalia maintained for the purpose. To such Universities the Colleges at once concede special privileges for their students. But what about the other *soi-disant* Universities, such as the Royal Irish University? It is, in fact, no more a University in the educational sense than is the Intermediate Examination Board, nor are its matriculants University under-graduates. Such institutions are mere examining centres; they have no attached Colleges; they neither educate nor supervise their students: they possess no museums, libraries, or other teaching appliances, and they never see their so-called under-graduates from year's end to year's end. Why should the matriculants of Universities of this class be entitled to any special privileges? Have they earned them by superior culture? Not at all; their matriculation examinations are in no way superior in quality to the preliminary examinations of the Colleges. Have they undergone academic study and discipline? No; for their University requires no residence, and has no place wherein they could reside. Have they paid for University education? Certainly not. They have, many of them, been taught by the Colleges, and by means of those museums, libraries, and schools for which it is now claimed that they should not pay; and they have never entered their University, save to pass an examination, just as a school-girl goes to Cambridge to pass one of the ordinary local examinations. I repeat that an examining centre is not a University, whatever it may call itself; and a student who goes up for one of its examinations is not an under-graduate, and is entitled to no special privilege whatever. He is as well examined in any College, and is educated without any assistance whatever from his "University," and, being so educated, he should pay for the sources of his education. This cheap admission to the final examination is, in fact, neither more nor less than a money bribe to attract the student to these institutions. For example, a student under the new Bill who passes his preliminary examination at the Irish College of Surgeons, and pays ten shillings, is liable to pay the full sum which may be agreed upon for the final examination of non-University men; but if he passes at the Royal Irish University the same preliminary, with one insignificant additional Arts examination, and pays the same ten shillings, he is to be received at his final examination on the same easy-money terms as the student of Dublin University who has resided in Trinity College for four years, passed eight Arts examinations, and obtained a full graduation in Arts. The proposition is monstrous; and I can only account for it by assuming that the framers of the Bill forgot the existence of this class of so-called Universities.

I am, Sir, yours, &c.,

A. H. JACOB, M.D., F.A.C.S.I.

23, *Ely Place, Dublin*,
April 19th, 1884.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AT a meeting of the Royal College of Physicians, held on the 24th inst., the business was chiefly formal. Six qualified practitioners who had passed the examinations, conducted by the Censors Board, were admitted to the Membership of the College; and the licence of the College was granted to 44 gentlemen who had passed the required examinations, and 7 others who passed in medicine and midwifery will receive the license when qualified in surgery. The by-law, *pro hâc vice*, permitting the election of Fellows to take place this year, on the last Thursday in May, was agreed to. The Committee on Vice-Presidents reported, that in former times the President had power to appoint a Pro-President, and recommended the President should be empowered by by-law to appoint annually two Fellows from among those who have been Senior Censors, to be Vice-Presidents. This was adopted with the proviso, that no retiring Vice-President shall be re-eligible till after the lapse of five years. The report of the Finance Committee was of a very satisfactory character, and the Committee, in consideration of the greatly increased labours of the Censors Board, recommended that an additional *honorarium* of fifty guineas be granted to each of the present Censors at the expiration of their term of office. The Examiners for the Murchison Scholarship reported that fifteen candidates offered themselves as candidates; one retired, and all the rest showed a high standard of excellence. Mr. J. Bland Sutton, of Middlesex Hospital, was recommended for, and elected to, the Scholarship. Mr. R. Fortescue Fox was mentioned as having closely equalled Mr. Sutton in all his work.

MEDICAL OFFICERS OF SCHOOLS' ASSOCIATION.

According to the proposal made in the journals, the first meeting of the above-named new society was held at Christ's Hospital, London, on April 16th, when many medical men, representing all classes of schools were present. The objects of the Association were declared to be, (1) mutual assistance in promoting school hygiene; (2) meetings for the consideration of all subjects connected with the special work of medical officers of schools; and all present or retired medical officers of schools, of children's hospitals, and medical men specially engaged in the study of the ailments of the young, are eligible as members. It was decided to hold three ordinary meetings in the course of the year, the next in July during the conference on school hygiene, to be held at the International Health Exhibition. The following gentlemen were elected on the Council:—*President*, Surgeon-Major Evatt, Royal Military College, Woolwich. *Vice-President*, Dr. Fuller, Lancing College. *Hon. Secretary*, Dr. Alder Smith, Christ's Hospital. *Treasurer*, Noble Smith, Esq. Members of Council—G. Armstrong, Esq., Wellington College; W. Armstrong, Esq., Royal Hospital School, Greenwich; Dr. Haig Brown, Charterhouse; Dr. Brett, London Orphan Asylum; Dr. Fletcher Beach, Darenth Asylum; Dr. Adams Clarke, Leavesden Schools; Dr. Ingle, The Leys School, Cambridge; Surgeon-Major Lever, Military College, Oxford; Dr. Prangley, N. Surrey District Schools; Dr. Shelly, Haileybury; H. Statham, Esq., The Foundling; T. Pridgin Teale, Esq., Leeds. The secretary will be glad to receive the names of any medical men wishing to become members of this Association.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma were admitted Members of the College, at a meeting of the Court of Examiners on the 21st instant, viz.:—Messrs. J. F. Bateson, M.B. Edinburgh, Wavertree; W. H. Owen, L.K.Q.C.P. Ireland, Liverpool; H. H. Marsden, L.K.Q.C.P. Ireland, Birkenhead, of the Liverpool School of Medicine; H. D. James, L.S.A., Babbicombe, Devon, and H. C. Dent, L.S.A., Woolwich, of King's College Hospital; W. H. Starr, L.S.A., West Kensington Park, and O. P. Brown, L.S.A., Percy Circus, W.C., of St. Bartholomew's Hospital; J. C. Evers, L.S.A., Stourbridge, and T. Birt, L.S.A., Stourbridge, of the Birmingham School; C. G. Satchell, L.S.A., Tunbridge Wells, of University College Hospital; W. F. Miller, M.B. Melbourne, Melbourne, of the Melbourne University; A. Fuller, M.B. Edinburgh, Cape Town, of the Edinburgh School; R. Hardie, M.B. Durham, Newcastle, of the Newcastle School; R. H. Hunter, M.B. Glasgow, Glasgow, of the Glasgow School; S. A. Davies, L.R.C.S. London, Llanelly, of Guy's Hospital; A. G. Andrews, L.R.C.S. London, Coleshill-street, S.W., of St. George's Hospital; and S. Plowman, L.S.A., of St. Thomas's Hospital. Five gentlemen were approved in Surgery, and when qualified in Medicine will be admitted Members of the College; four candidates were referred for three months, two for six months, and one for nine months. The following gentlemen passed on the 22nd instant, viz.:—Messrs. J. W. McVitre, L.R.C.S. Edinburgh, Liverpool, and J. G. G. Corkhill, L.R.C.S. Edinburgh, Bootle, of the Liverpool School of Medicine; J. H. Harris, L.S.A., Abestyberg, and J. R. Nunn; L.S.A., Burton-on-Trent, of St. Bartholomew's Hospital; H. C. Coe, M.D., Harvard, Detroit, of the Harvard University; A. B. Gemmel, L.R.C.S. Edinburgh, Glasgow, of the Glasgow University; A. Hepworth, M.B. Durham, Newcastle-on-Tyne, of the Newcastle School of Medicine; W. G. Anglin, M.D., Kingston, Ontario, of the Kingston School of Medicine; G. E. Hale, L.R.C.S. Edinburgh, Elgin-road, W., of St. Mary's Hospital; E. A. Fall, L.R.C.S. Edinburgh, Kensington Gardens Square, of University College Hospital; and A. T. J. Lilly, L.R.C.S. London, Woolston, Southampton, of St. George's Hospital. Six gentlemen were approved in Surgery, and when qualified in Medicine will be admitted members of the College; five candidates were referred for three months, and seven for six months. The following gentlemen also passed their examination on the 23rd instant, viz.:—E. G. F. Morris, Bromzard, of the Leeds School of Medicine; L. Jones-Bateman, B. A. Cantab, Birmingham, of the University of Cambridge; W. O. Shaw, Basingstoke; G. L. Barritt, L.R.C.C.L., Todmorden, and J. H. Gough, Manchester, of the Manchester School of Medicine; H. L. Pearson, Rockferry, Liverpool School of Medicine; H. H. Tomkins, Bristol, Bristol School of Medicine; F. W. Gordon, Dublin, Dublin School of Medicine; G. L. Wells, Leeds, and E. C. Pettifer, Stoke Newington Green, St. Bartholomew's Hospital; D. Thomas, Abberffraw, Mon., London Hospital; W. R. Edwards, Caerleon, Newcastle School of Medicine; G. C. E. Anderson, Cape Colony, and W. L. Braddon, Upton-on-Severn, Guy's Hospital; G. W. H. Trench, Hornsey, St. Mary's Hospital. Five candidates who passed in Surgery at previous meetings of the Court, having subsequently obtained medical qualifications, were admitted Members, viz.:—J. T. Tupholme, L.R.C.P.Ed., South Kensington, of St. Bartholomew's Hospital; A. de Winton, L.R.C.P.Ed., Gloucester, and G. F. Hugill, L.S.A., Chislehurst, of Guy's Hospital; T. F. Foster, L.S.A., Brampton, King's College Hospital; J. R. L. Dixon, L.R.C.P.Ed., Liverpool, of the Liverpool School of Medicine. Four candidates passed the examination in Surgery, one candidate was referred for three months, and four for six months.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 17, 1884:—

Anderson, James Johnstone, Vine Street, Lincoln.
Birt, Thomas, High Street, Stourbridge.
Brown, Osmand Percy, Percy Circus, Pentonville.
Harrison, Joseph, Wilford Street, Bradford.
Hewer, Henry John, 33, Highbury New Park.
Kirkhouse, George, 1, Romilly Road, Finsbury Park.
Musgrave, Frank Ernest, Leopold Street, Leeds.
Scott, Alfred Langston, Thornton Hill, Wimbledon.
Tatam, Edwin Charles, Wetherby, Yorkshire.
Woodson, Adolphus Arthur, Fitzalan Square, Sheffield.

The following gentlemen also, on the same day, passed their Primary Professional Examination:—

Foster, Albert Ernest, Leeds School of Medicine.
Visger, Harman, Bristol School of Medicine.

University of Glasgow.—The following candidates have passed the First Professional Examination (Natural History, Botany, and Chemistry):—Frederick Ashurst, Charles Banks, James A. Brown, James Bruce, Alexander Butler, Saxon S. Dale, Thomas T. Downie, David Elliot, William R. Forrester, William Gemmell, Andrew Gray, Harry Gray, Archibald Gunn, Edward O. Harrison, R. C. Highet, G. F. Hilliard, Robert Hogg, Arthur D. Hughes, George J. Imrie, John A Jackson, Thomas Kirkland, James Marshall, William Marshall, Thomas L. Macfarlane, Robert M'Ghie, George M'Intyre, C. A. Mackechnie, William T. Nicholson, Hugh Rhodes, Henry W. Robinson, William P. Sandilands, Charles E. Scanlan, Henry W. Sinclair, J. W. H. Steil, Robert Stevenson, Edward B. Tant, James A. Ure, and Andrew S. Wotherspoon. The following candidates have passed the Second Professional Examination (Anatomy and Physiology):—William M. Alexander, M.A., John Allan, W. Carrick Allan, Samuel J. Baird, Charles William Bell, H. Duncan Browne, Alexander Bryce, William Butchart, M.A., Archibald T. Campbell, Robert Craik, William C. Crichton, John Currie, George W. Davis, J. L. Downs, William J. Giblin, John R. Gibson, John D. Gordon, Charles Gray, Yousuf Hamiz, Walter Hay, Herbert Hickin, John Hogg, James E. Hunter, William Huntly, M.A., George Marshall, J. G. Marshall, Alfred E. Miller, George Miller, Donald S. MacColl, J. R. R. M'Crindle, Tom Macdonald, John M'Keith, Archibald Maclachlan, William M'Millan, Charles M'Taggart, M.A., Andrew H. Richmond, John Ritchie, John Rowat, Thomas Rutherford, B.A., David Stiell, James Watson, Leonard Williams, James Wilson, M.A., William Yorke, and Robert R. Young. J. W. Shane passed the Second Examination, Old Regulations (Anatomy, Physiology, Zoology.) The following candidates have passed the Third Professional Examination (Regional Anatomy, Materia Medica and Pharmacy, and Pathology):—Archibald S. Alexander, Samuel P. Alexander, William Allan, Alexander M. Bankier, John Broom, Hugh D. Buchanan, John Buchanan, J. Wilson Cameron, William

D. Campbell, Quintin Chalmers, Robert Cook, Charles Court, B. S. Cowen, David K. Cross, William Cullen, Henry E. N. Dobie, John Dodd, James Dunlop, M.A., Robert Eaglesham, Robert M. Fleming, Robert C. Gilroy, John Graham, Ernest W. Haydon. Wm. J Holme, John Hughes, Hugh Kelly, John A. Kerr, William Kirkland, Trafford Mitchell, Wm. C. C. Muir, James I. Macarthur, Thomas C. M'Culloch, John A. Macdonald, Roderick Macdonald, Digby M. Macphail, Alexander M. Macrae, Henry J. Neilson, James Parker, W. Whiteside Paterson, Andrew Richmond, David Roxburgh, Walter Sandeman, Wm. M. Semple, William Seright, Robert M. Service, William Shand, Walter W. Spence, Charles D. Temple, Allan Watt, Charles Whish, John White, Andrew Wilson, James Wilson, John S. Wright.

University of Aberdeen.—At the late Medical Graduation Term, the following candidates, after the usual examinations, received degrees in medicine and surgery:—*Degree of M.D.*—Alexander Theodore Brand, M.B., C.M., Driffield, Yorkshire; William Carnegie Brown, M.B., C.M., Penang; Silvester Williamson Findlater, M.B., C.M., Dufftown; Timothy Siddall Jones, M.B., C.M., Swansea; James Millar, M.B., C.M., Arbroath; John Hay Moir, M.B., C.M., Burton-on-Trent; Charles Lloyd Tuckey, M.B., C.M., London; James Hutchison Walker, M.A., M.B., C.M., North Borneo. *Degrees of M.B. and C.M.*—Henry M'Kenzie Adamson, Morphie, Montrose; George Henry Allden, Southampton; John Hector Anderson, Aberdeen; Joseph Anderson, Preston; Albert Henry Barrett, Wallingford, Berks; Christopher George Battiscombe, Blackheath; Francis Alexander Bennet, M.A., Cullen; William Ronaldson Clark, M.A., Edinburgh; James Will Cook, Allness; Alexander Mitchell Cowie, Mortlach; James Forsyth Craig, M.A., Leslie, Insch; George Burnett Currie, M.A., Aberdeen; Henry Moger Cyrill Dalton, Newcastle, N.S. Wales; George Duffus, Cullen; Walter Angus Elmslie, Resthwet. Chapel of Garioch; Charles Albert Faulkner, Rajahmundry; John Andrew Fehrsen, Graaf Reinet, S. Africa; William Revely Forster, Blyth, Northumberland; John Gordon, Keith; Thomas Bell Graham, Ecclefechan; Andrew Grant, Balmoral; John William Harrison, Sandwich, Kent; Charles Robert Lyall, Aberdeen; Stuart Macdonald, Elgin; Frank Innes Macintosh, M.A., Deskford, Cullen; Alexander Maclean; F.R.C.S. Edin., Thurso, Caithness; George Milne, Methlic; James Mitchell, Aberdeen; James Mitchell Munro, Inverurie; Alexander Murchison, Lochcarron; Eapen Poonen, B.A., India; Robert Dowell Presslie, Aberdeen; Alfred Ernest Roberts, London; William Robertson, M.A., Rathen; William Ledingham Ruxton, West Riding Asylum, Wakefield; James Savege, Montrose; William Leith Ireland Sutherland, Aberdeen; Herman Thiele, Bermuda; Leslie Fyfe Walker, Aberdeen; John Eustace Webb, Windsor; James Will, Ellon; John Thomas Windle, Burnley. Of the above-named candidates, George Henry Allden, William Ronaldson Clark, John Gordon, Alfred Ernest Roberts, James Will, received their degrees in medicine and surgery, with honourable distinction. The John Murray Medal and Scholarship was awarded to Arthur Greatorex Smith, and will be presented to him along with his diplomas on his attaining the necessary age. At the same time, Arthur Stephen Inglis was certified as having passed all the examinations, but did not graduate.

The Port of London Hospital.—The hospital which has been erected near Gravesend, to supersede the floating hospital *Rhin*, was opened by the Lord Mayor on Thursday, the 17th inst.

The *St. James's Gazette*, which has already given evidence of being inspired on the subject, tells us that "An important step is about to be taken by the Kensington Board of Guardians, so soon as they have obtained the consent of the Local Government Board, which there is no reason to think will be refused. This is the introduction of clinical lectures delivered by the resident medical officer in the wards of the workhouse infirmary to a following of six medical students, who will be allowed to reckon this instruction as a part of their professional education in connection with the West London Hospital. This may possibly be only the beginning of an important movement, which must end in the introduction of the regular hospital system with the school of students. The change may possibly be beneficial in many ways; to the patients, because they will be better attended to when the education of a body of remunerative pupils depends upon the careful study of their diseases; to the doctors, by opening out a wilder field than the crowded posts attached to voluntary hospitals afford, and by providing the opportunity of studying long and chronic cases which are more rarely met with and not often traced to their end in hospitals; to the resident officers, matron, and nurses, by bringing a fresh energy and zeal into the workhouse infirmaries, encouraging a high standard of work and remorselessly stamping out jobbery and exposing inefficient and perfunctory nursing and management."

The Medical Bill.—The *Times*, in a leading article on the Medical Bill, says:—"The machinery to be created is somewhat cumbrous, and will probably be costly; but it seems likely to attain the end proposed. It will do away with the scandal of the present competition for the patronage of the less instructed students; for the licensing bodies which have always maintained their standard will form majorities on the Boards and in the Council. The proposal that a few members of the Council should be elected by the profession is one which it would be difficult to defend on any ground of reasonableness; and, while it will give a great deal of useless trouble, the best which can be said for it is that it will probably not do much harm. It will be likely to remove one or two eminent men and to replace them by busybodies who take the trouble to canvass; but the busybodies, if such should be elected, will be insignificant in point of numbers."

Erratum.—In the article on "Paraldehyde as a Narcotic," (*Medical Times*, April 19th, 1884, p. 537) for Cirullo read Cirvello, and for grains read grammes.

Society for the Relief of Widows and Orphans of Medical Men.—A Quarterly Court of the Directors of this Society was held on Wednesday, April 9th, at 8 p.m. Sir James Paget, Bart., President, in the Chair. A letter was read from Sir George Burrows, late President, in answer to a resolution passed at the last Court on his resignation of Presidentship. The death of a widow, receiving 50*l.* per annum, was reported; there were no fresh applications for relief. Four new members were elected, the deaths of two announced, and the resignation of another. The half-yearly applications from the widows and orphans on the funds were read, and it was resolved that a sum of 1,162*l.* be granted at the next Court to 57 widows, 5 orphans, and 3 recipients from the Copeland Fund. It was also resolved that Mr. James T. Ware and Sir Erasmus Wilson be nominated Vice-presidents in the place of Sir James Paget, elected President, and Mr. Charles Hawkins, resigned, and that Dr. Kempster, Mr. Stamford Felce, Mr. Brodhurst, Mr. Iowne, jun., Dr. Herbert Davies, and Dr. Russell Reynolds be nominated Directors in the place of the six seniors who retire. Tuesday, the 13th of May, was fixed for the Annual General Meeting at 5 p.m.

The Recent Operations in the Soudan.—H. M. Indian troopship arrived at Portsmouth on Monday, bringing home about 60 sick and wounded, including Surgeon Cross, R.N., and Surgeon Prendergast, A.M.D. Throughout the campaign the *Jumna* did duty as a hospital ship, affording cot-accommodation for 180, and even upon an emergency for as many as 250 men. The medical requirements were under the direction of Surgeon-Major Vermont, A.M.D., who has been assisted by Surgeon-Majors Greene and Morgan, and Surgeons Chapman, Flood, Brown, and Pedlowe. On the passage home only one death occurred, viz., from enteric fever. Many of the sick and wounded made satisfactory progress during the voyage, and the number of cases requiring to be sent to the Royal Hospital at Netley will be considerably less than was at one time feared.

Volunteer Ambulance Work.—In connection with the recent Dover Manœuvres, Deputy-Surgeon-General Stewart has reported very highly of the thorough practical knowledge and smartness displayed by the volunteers in ambulance work, in the employment of improvised splints, such as rifles, bayonets, &c., in the treatment of supposed fractures, and in the application of tourniquets, &c., for the arrest of hæmorrhage from wounded arteries.

CREMATION.—The Council of the Parkes Museum have decided to arrange in the Museum a collection of models and illustrations of objects relating to cremation and improved forms of burial and disposal of the dead, as a supplement to the International Health Exhibition, this subject not being included in the classification of that Exhibition. The Council will be very glad to receive offers of models, or other information, as they wish to make the collection fully representative of the latest and most approved plans and methods.

SHOP ASSISTANTS.—Sir John Lubbock has undertaken to introduce a Bill in the House of Commons for the purpose of regulating the hours of labour of shop assistants, and improving the sanitary conditions under which their work is carried on.

WOMEN-DOCTORS IN PHILADELPHIA. — At a largely attended meeting of the Philadelphia County Medical Society, on April 2nd, a proposal was made to amend its constitution, with the view of permitting the admission of female physicians to membership. The proposal was supported by 79 votes, and opposed by 48 votes, but as a two-thirds majority is required before any change in the constitution of the society can be accepted, the proposal was lost.

APPOINTMENTS.

BARLING, GILBERT, M.B., F.R.C.S.—Honorary Assistant Surgeon to the Birmingham Orthopædic and Spinal Hospital.

DONALD, ARCHIBALD, M.B., C.M. Edin., M.R.C.S.—House Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

DRUITT, LIONEL, M.D., C.M. Edin., L.R.C.P.—Medical Officer to the South Lambeth District.

FRASER, T. A., M.B., C.M. Edin., M.R.C.S.—House Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

GREEN, JAMES U., L.R.C.S. Edin., L.R.C.P. Edin.—Medical Officer to the First and Second Districts, Woodbridge Union.

JONES, GEORGE H. W., M.R.C.S. Eng., L.S.A.—Medical Officer to the Eckington District, Chesterfield Union.

LLOYD, R. W., L.R.C.P., M.R.C.S.—Administrator of Anæsthetics to the West London Hospital.

LUCKMAN, E. L., M.R.C.S., L.R.C.P.—Surgeon to the Altrincham Hospital and Dispensary, *vice* W. O. Jones, resigned.

MIDDLETON, A. H., L.R.C.S.I.—House Surgeon to the City of Dublin Hospital, *vice* J. D. Pratt, M.B.

OLIVER, J., M.B.—Assistant Physician to the Hospital for Women, Soho Square, W.

OSBORN, S., F.R.C.S.—Assistant Surgeon to the Hospital for Women, Soho Square, W.

STRICKLAND, CHARLES, E., M.R.C.S. Eng., L.K. and Q.C.P. Ire.—Medical Officer to the Kidsgrove District, Wolstanton and Burslem Union.

STURGES, OCTAVIUS, M.D., F.R.C.P.—Physician to the Hospital for Sick Children, Great Ormond Street, *vice* W. H. Dickinson, M.D., resigned.

VEALE, HENRY, M.D.—Physician to the Essex and Colchester General Hospital, *vice* A. Wallace, M.D., resigned.

WATSON, JOHN W., M.R.C.S. Eng., L.S.A.—Medical Officer to the Fourth District, Ashby-de-la-Zouch Union.

WESTBY, GEO., M.K., Q.C.P., L.R.C.S.—Honorary Assistant Surgeon to the Liverpool Hospital for Cancer and Skin Diseases.

WILSON, RICHARD, M.R.C.S. Eng., L.S.A.—Medical Officer to the Grantham District, Grantham Union.

VACANCIES.

BIRMINGHAM PARISH.—Medical Officer for the Fifth District, in succession to Mr. John Darwen, deceased. Salary, £175 per annum.

CHELTENHAM GENERAL HOSPITAL. — Junior House Surgeon and Chloroformist. Salary, £20 per annum, with board and lodging. Candidates must possess a registrable qualification, and be unmarried. Application, stating age, with testimonials, to be sent to the Honorary Secretary, on or before May 3rd.

CHESHIRE COUNTY ASYLUM, PARKSIDE, MACCLESFIELD.—Medical Superintendent. Salary, £500 per annum, with furnished house, &c. Candidates must be duly qualified and registered Medical Practitioners. Full particulars can be obtained on application. Applications and testimonials, with 30 printed copies of the latter for circulation among the committee, to be sent to Mr. A. C. Procter, on or before May 3rd.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.—Assistant Physician. (*For particulars see Advertisement.*)

HOSPITAL FOR DISEASES OF THE THROAT, GOLDON SQUARE, W.—Two Surgeons. Candidates must be Fellows or Members of the Royal College of Surgeons of England. Applications, with testimonials, to be sent to the Committee not later than May 2nd.

MACCLESFIELD GENERAL INFIRMARY. — Junior House Surgeon. Salary, £70 per annum, with board and residence in the Institution. Candidates must be doubly qualified and duly registered. Applications to be sent to the Chairman, House Committee, Macclesfield Infirmary, on or before May 3rd.

TOWN AND DISTRICT HOSPITAL, NEWARK-UPON-TRENT. — House Surgeon and Secretary. Salary, £100 per annum, with board and lodging. Testimonials to be sent not later than May 1st.

DEATHS.

BECHER, EMIL, M.D., Brigade Surgeon, at Stuttgart, on April 14th, aged 55.

FIELD, OCTAVIUS A., F.R.C.S., at the Manor House, Southall, on April 21st, aged 72.

FREEBORN, FERNANDEZ, M.D., F.R.C.P., M.R.C.S., at Oxford, on April 20th, aged 60.

REYNOLDS, JOHN SWATMAN, L.R.C.P., &c., at 22, Denmark Road, Lowestoft, on April 9th, in his 35th year.

STONEHAM, PHILIP, M.R.C.S., at Ilfracombe, on April 16th, aged 76.

UNSWORTH, FRANCIS HENRY, M.R.C.S., L.S.A., at Beechworth, Victoria, on February 16th.

NOTES, QUERIES, AND REPLIES.

A NEW METHOD OF REDUCING DISLOCATION OF THE LOWER JAW.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—A young lady, aged 16, was brought to me by her aunt for consultation last month, with slight deformity of the face. About two years ago she had a fit of yawning, and since that she had noticed a contraction in the entrance to her right ear; she could not introduce her little finger on that side so easily as on the other. On bidding her to force the little fingers into the ears, while I manipulated with the articulation, and she opened and shut her mouth six times rapidly, we both heard a rapid snap, and felt the articulation enter its socket, and now hope that in time the face will take its normal position. Six weeks have passed, and the aunt has called to say, her niece is quite well, and her features are restored to order. Having related this case to a retired East Indian Surgeon, who had a great horror of finding his thumbs caught by the teeth during the reduction and rapid closing of the jaw, he immediately introduced his little fingers into his own ears, and was surprised on finding the joints move so well under his fingers; but said, he always used the protection and precaution of strong gloves with the natives of India.

I am, Sir, yours, &c.,

18, *Power Road, Brighton.* R. TUTHILL MASSY, M.D.
April 18th, 1884.

The late Duke of Albany.—The President, Vice-Presidents, and Council of the Royal College of Surgeons of England have sent the following Address to H.M. the Queen:—"May it please your Majesty, We, the President, Vice-Presidents, and Council of the Royal College of Surgeons of England, venture to approach your Majesty, in order to express our profound sorrow at the sad calamity which has fallen upon your Majesty and your Majesty's House, and which has filled the whole nation with the deepest grief. We deplore the loss to your Majesty of so beloved a son, and to the nation of so cultured and amiable a prince; and we humbly offer to your Majesty our tribute of admiration to the high character and qualities of His Royal Highness, the lamented Duke of Albany, and our heartfelt sympathy with your Majesty and your Majesty's family, in this great affliction. We ask leave to express, through your Majesty, our sincere condolence with Her Royal Highness, the Duchess of Albany, in her overwhelming bereavement."

Collegiate Examinations.—The following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the candidates for the diploma of Membership of the Royal College of Surgeons on the 18th instant, when they were required to answer at least four (including one of the first two) out of the six questions between the hours of 1.30 and 4.30 p.m., viz.:—1. Mention the relations of the trachea. 2. Describe the course, relations, and anastomoses of the plantar arteries. 3. Contrast the clinical characters and history of an innocent and of a malignant tumour. 4. Describe the mode of formation and treatment of fistula in perinæo. 5. Give the various means of arresting arterial hæmorrhage in recent wounds, with the advantages and disadvantages of each method. 6. Under what circumstances would you advise the removal of a portion or of the whole of the tongue?

The following were the questions on Midwifery and Diseases of Women submitted on the following day, when they were required to answer three out of the four, viz.:—1. Describe the clinical history of the vomiting occurring during pregnancy. How would you treat a case in which it is so severe as to impair health? 2. How would you distinguish the breech from the face when presenting? How would you treat a case in which the face presented at an early stage of labour? 3. Describe the cranioclast and the operation "cranioclasm." 4. To what morbid conditions may gonorrhœa in the female give rise? Describe briefly the symptoms and treatment of each of the complications you mention.

The following were the questions on the Principles and Practice of Medicine, when three out of the four questions (including No. 4) were required to be answered:—1. Discuss the morbid anatomy,

symptoms, and consequences of exophthalmic goitre, or Graves's disease. 2. What are the specific symptoms due severally to disease of the posterior columns of the cord, disease of the lateral columns, and disease of the anterior grey horns? 3. What are the causes of abdominal dropsy, and what the signs and symptoms of its presence? 4. What are the medicinal properties, the uses, and the doses of the following drugs—dilute nitric acid; subnitrate of bismuth; confection of senna; creasote; elaterium; extract of cannabis indica; liquid extract of opium; and mistura ammoniaci?

The list of successful candidates appears on another page.

Dr. Young, Hongkong, China.—Letter and enclosure received with thanks.

APPOINTMENTS FOR THE WEEK.

Friday, April 25 (this day).

Clinical Society of London.—Meeting. The following Papers will be read:—Mr. Gant, "A Case of Epithelioma of the Tongue;" Mr. Turner, "A Case of Gluteal Aneurysm;" G. M. W. Arbuthnot Lane, "Extensive Venous Thrombosis following Fracture of the Forearm;" D. Lediard, "Fracture of the Coronoid Process, with Dislocation backwards of both Bones of the Forearm."

Saturday, April 26.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Royal Institution, 3 p.m.—Mr. H. M. Westropp, "Roman Archæology: The Colosseum."

Monday, April 28.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Medical Society of London.—Dr. Cayley and Dr. Gibbes will read a Paper on "A Case of Ulcerative Endo-carditis, with Microscopic Specimens;" Dr. J. Kingston Fowler, "A Contribution to the Pathology of Hydro- and Pyo-salpinx."

Tuesday, April 29.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Royal Institution, 3 p.m.—Dr. Klein, "Nerve and Muscle."

Wednesday, April 30.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, May 1.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Royal Institution.—Annual Meeting at 1.30 p.m. Prof. Dewar, "Flame," &c., at 3 p.m.

Friday, May 2.

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m.—Prof. Judd, "Krakatoa."

CONTRIBUTIONS TO THE HISTORY AND TREATMENT OF NERVE DISORDERS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.,
Physician to St. Mary's Hospital.

Sciatica.

THE first of the subjoined cases of this malady was one of more than usual difficulty and interest, the others are of a more ordinary quality. All, however, I venture to think, will repay perusal.

Case I.—J. W., aged 60, costermonger, admitted March 25th, 1883. A tall gaunt man, well made. Had rheumatic fever twenty-four years ago, and several times since. Last ten years has had sciatica severely in left leg and thigh, and lately has had a good deal of bronchitis, for which he is now in hospital. The bronchial catarrh commenced about March 4th, is attended with thick greenish expectoration, and with dry and moist sounds over both fronts and backs, especially at the posterior bases. Lower ribs do not expand anteriorly. Heart fairly normal. Pulse 72, full, regular. Radial artery extremely cordy, but on compression of the brachial, the radial ceases to be felt. Splenic dulness of moderate extent. No ascites. No history of syphilis. Urine clear, and no albumen. Pain plays from point of exit of sciatic nerve, from pelvis to ankle; is worse in cold weather. The pain has been so severe as to prevent him from following his occupation. He says that he has often been obliged to drop his basket and throw himself on the ground. Some two or three years ago, the operation of nerve-stretching was performed, but the result of it, according to his own account, was by no means favourable; he was easier for a few days, but soon became worse than he had been before. My colleague, however, who performed the operation tells a very different tale; he affirms that the patient was free from pain for four months after the operation, and was much benefited for a year, and wished to have the operation repeated after the pain returned in force. My colleague's statement is confirmed by others, and of course is much more reliable than the patient's, but there is no question that, for more than a year before he came under my care, he was suffering very severely from sciatic neuralgia. He used to haunt the hospital continually, and plague the resident officers with his importunity for subcutaneous morphia, which was the only thing that relieved him. He had used it, he says, for ten years, but latterly he was obliged to have it twice a day, and in double quantity. His dose was ℥ xv, of the hospital solution, *i.e.*, nearly gr. i. The drug had certainly deteriorated his nerve-power, he was quite a victim of the morphia habit. Yet, I think we should remember that he was enduring grievous pain, and had endured it for many years, and should not rank him among those who have not his excuse for abusing

the remedy which, properly employed, well deserves its appellation "divine." Pain, long and severe, makes sad havoc in the harmonies of our many-stringed harp, and in my experience, as well as in that of others, has altered a naturally sweet and graceful *morale* grievously for the worse. Churchill tells the story of a very sweet-tempered woman, who, under protracted uterine suffering, became—to use her own words—so cross, that there was no living in the house with her. So this poor fellow, either from morphia, or from pain, or from both together, was a very wreck. I have rarely, if ever, met with a more discouraging case. My note about him, after three weeks' observation, runs to the effect, that he is very morose and unhappy, always craving for morphia on account of his pain. I saw that the morphia must be abandoned, if there was to be any hope of a thorough cure, and I had cut down his allowance of it considerably. On this account he regarded me with no good will, and always met me on my visit with a scowling gloomy face, and the sullen reply to my enquiry, "No, sir, I'm not a bit better." On April 23rd, he was more restless and discontented than ever, still hungering for morphia, and had almost made up his mind to leave the hospital. By this time his bronchitis was a good deal better, having been treated with Mist. Scillae c. Ferro ter die, and with pills of Ipecac. gr. ½, Opii gr. ¼ tertiis horis, until April 7th. Five days before he had begun phosphorus in doses of gr. $\frac{1}{33}$ ter die, and two days later he commenced Tonga in ℥i doses, which he took for a week, but the sciatica was nothing bettered. Twice about this time acupuncture was practised, but ineffectually. Examination made *per rectum*, detected no tumour, nor anything abnormal on either side of the pelvic outlet, save that there was more tenderness on the left than on the right. On April 27th, he was ordered Quiniæ Disulph. gr. v quater die, which produced some cinchonism, and was reduced to gr. v ter die on May 3rd, when Ferri Carb. Sacch. gr. 20 bis die was also added. On May 28th, the quinine was replaced by Ol. Terebinth. rect. ℥ xx ter die. Phosphorus omitted.

May 31st.—The old pain in the left thigh is confessedly better, but he suffers with darting pain in the peroneal region of leg, extending from the outer side of the knee to the ankle. It is worse at night, but he sleeps well now without morphia. The left lower limb is weaker than the right, he cannot walk well without the help of a stick. Phosphorus and carbonate of iron omitted three or four days ago. June 4th.—He feels better in himself since he has taken the Ol. Terebinth., but it has not relieved the pain in left ankle. Benzol to the part has done some good. Ordered Calcis Hypophosphitis gr. xv, Tr. Calumb. ℥ xv, Aq. ℥i. ter die, and to continue Ol. Morrh. which he commenced some while ago. On June 7th, an ice-bag was ordered to the left lumbar region; this rendered his feet much warmer, but reproduced pain in the hip, so it was not continued long. On 15th, galvanism was ordered daily to the leg; I cannot say how long it was employed, for I did not observe any marked benefit from it. By June 25th he was much more cheerful; according to the ward-sister's report, he was quite a different man. He walked about stiffly, halting on his left leg; felt less pain in the ankle, but it was still very rigid; at times I could not move it at all, at others but slightly. No ankle clonus in either leg. No knee-jerk in *either* leg; this was ascertained on repeated and careful trials. He was quite unable to flex the knee against the force of my arm resisting, while lying on his back. It is difficult for me to flex the knee, the leg being kept extended by powerful contraction of the quadriceps extensor. By gentle management this resistance can be overcome, and the knee flexed to an angle of 45° with the surface. Considerable pain was felt at posterior part of hip and thigh on passive extension or flexion of the knee. The knee and hip-joints are quite free and mobile, but not so the left ankle. The left lower limb appears as large as right, measurement over both calves is equal. He says he has gained flesh largely in the left limb, at one time it was much wasted. Ordered Ammonii Bromidi gr. x, Sodii Bromidi gr. x, Inf. Cascarill. ℥i. ter die. Pt. c Oleo. 28th.—Two days ago he complained of very severe pain, much worse than usual, and increased pain was felt also in knee. To-day this aggravation has subsided (it was probably due to the prolonged examination on 25th), and he has a good deal less pain than a week ago. Knee-jerk is now produced pretty readily in right leg, and tolerably after some trials in left, but not so well as in right. No cremaster reflex on either side. Never had any difficulty either with bladder or bowel. Ankle (on 30th) feels hot and throbbing, but has lost the dull aching pulling pain. Can "work" his ankle, *i.e.*, flex and extend it very much better than he could, but it is still very tender to handle. July 7th.—He sleeps much better, longer at a time; used only to get short bouts. Can flex his ankle well, raising the toes four inches or so from the floor. Complains of great sense of weakness about lower part of leg and ankle, but bears pressure on ankle better. Knee-jerk can be obtained in both legs with about equal facility, but not on every trial. 21st.—Two days ago left foot was much more mobile, and could be moved freely in flexion and extension with but little pain. There was no ankle clonus. Knee-jerk can be obtained in a pretty well marked manner about once in three trials in left leg. Can walk well even without a stick, though he evidently prefers it, and can stand a little on left leg. Some pain is felt at outer side of foot, and there is tenderness at a spot a little behind outer malleolus. Blister of half-crown size to this part. Omitr. Bromida. Sodii Hypophosphitis gr. xv, Tr. Calumb. ℥ xv, Aq. ℥i. ter die. Aug. 30th.—The first blister having agreed with him fairly well, a second was applied on July 26th, two or three inches higher up at the outer part of the left leg; it was made by painting just like the first. Its effects have been quite disastrous, the area affected ulcerated, a large slough formed about its middle, and is now only just detached. The ulcer seems little inclined to heal, is covered with a thin yellowish grey layer forming a network, the meshes of which are occupied by red granulations. No application agrees with it except carbolic lotion, all others cause pain. His general health continues good. From Aug. 9th to Aug. 27th he had Tr. Cinch. ℥iss, Ammon. Carb. gr. 4, Dec. Cinch. ℥i ter die. Afterwards he resumed the hypophosphite mixture. Extr. Belladon. gr. ¼ ter die was tried for some time, but was not of any material use. Sept. 25th.—The ulcer progresses in healing very slowly, it is still about 1½ in. by 1 in., but looks well and is granulating normally. He has an excellent appetite, sleeps well, is free from pain, is in good flesh, makes no complaint. He is, in fact, quite a different being from what he was five or six months ago. The only abnormality I observe is a good deal of twitching of some muscular fasciculi in the left calf, when his leg is lying on the bed on its inner side. He has continued the hypophosphite mixture till now, and the cod-oil probably. The small veins of the foot have been a good deal enlarged, and he has kept the foot elevated a good part of the day to promote the return of the venous blood. He left the hospital late in September, and went for three weeks or four to the Walton Convalescent Asylum. He presented himself on Oct. 18th, quite well, the ulcer healed, he looked blooming, and walked without a stick. I asked him on leaving his opinion of nerve-stretching, but he shrugged his shoulders and shook his head.

Case II.—E. J., aged 50, admitted January 23rd, 1883. Family history good. He had typhoid nineteen years ago,

small-pox seven years ago, gonorrhœa a good many years ago. No history of syphilis. Since he had typhoid he has been liable to rheumatic pains in his legs, worse during changes of weather. Six weeks ago he was forced to lie in bed with pains in his right leg, more especially in right hip. Health is otherwise good. His work is chiefly at night—a railway porter; thinks night-work takes more out of a man than day-work. Lungs and heart seem healthy. Temperature normal. Pulse 84, regular, firm. Abdomen large. Urine sp. gr. 1025, acid, clear, of orange colour, contains no albumen or sugar. Bowels open. Complains of pain all about right hip, and down the whole limb to the foot, the pain is constant and aching. No tenderness about hip, except a little outside the tuber ischii. Sitting on right tuberosity feels like sitting on a stone. The hip and foot have been cold and numb, but are warm now. Head of femur can be moved freely in acetabulum. His sleep is disturbed a good deal by pain. He was ordered Sodii Hypophosphitis gr. xv, Tr. Calumb. ℥ x, Aq. ℥i ter die, and Ferri Carb. Sacchi. gr. 20 bis die. February 1st.—Slept well. Pain less, it is now principally in the hip. He can stand better. Acupuncture employed. By February 19th, he was well and left hospital very soon after.

Case III.—W. W., aged 70, a fitter, admitted September 13th, 1882. Family history good as far as his children are concerned. Generally healthy. For the last month has had a great deal of pain in the right buttock, extending down back of thigh and leg to sole of foot. Much tenderness on pressure over sciatic nerve between tuber ischii and great trochanter. When pain first began, he found relief in walking about a little. When pain has been severe, he has had to keep the leg straight and quiet. Linim. Sinapis to buttock. Sodæ Hypophosphitis gr. 10, Inf. Cascarill. ℥i ter die. Pil. Hydr. c. Coloc. h. n. 21st.—Walks about much better, feels nicely, appetite good. Urine acid, sp. gr. 1020, no albumen. Hip joint is quite free. Pt. c Mist. c gr. xv ad ℥i. Ol. Morrh. ℥i bis die. 28th.—Pain increased yesterday, relieved by blister to hip. Distinct crepitus in right knee joint when handled, knees stiff in walking. October 5th.—Doing very well, wants to go out, walks about fairly well.

Case IV.—M. C., age 18, housemaid, admitted September 21st, 1878. Comes from Dorsetshire, has never had ague, or been in the way of it as far as she knows. Is a stout-made person, not at all anæmic. Her mother had sciatica, the family history otherwise is good. She has had no previous illness except dyspepsia, from which she has suffered during last six months, and severe sick headache. She has been suffering with pain in the left thigh for twelve months, it has been gradually getting worse, and is now so bad that it keeps her awake at night, and makes her walk lame. The pain extends from behind great trochanter to the back of the knee. When she kneels the pain is felt in front of and not behind the knee. Coughing hurts her at the hip. The pain is described as gnawing, and is worse when she is warm in bed. Bowels are generally open. Catamenia regular and sufficient. Heart-sounds normal. Pulse 72. Tongue clean. Has lost several molars. Urine free from albumen. Potass. Iod. gr. v, Sodæ Bicarb. gr. v, Dec. Cinch. ℥i ter die. Blister over sciatic nerve at its exit from pelvis. Diet ord. milk and beef-tea. 24th.—Subcutan. Morphia. 26th.—Repeat blister. Ferri Carb. Saccht. gr. xv ter die. 30th.—Much better, but has pain still on moving limb; has most pain when warm in bed at night, is sometimes quite free, mostly in afternoon. Port 4 ozs. Quiniæ Disulph. gr. v, Acid. Sulph. dil. ℥ vii, Aq. ℥i ter die. October 3rd.—Doing well, some pain and tenderness at crest of ilium on right, near sacro-iliac synchondrosis, pressing the two surfaces together causes pain. Blister. October 7th.—Benefit from last blister, but has pain now over exit of sciatic nerve. Firing with disc at 212° over seat of pain. 10th.—Is decidedly better, walks fairly well. Went out on 11th.

Case V.—E. S., aged 40, married, admitted March 15th, 1878. Married twenty years, and during that time has had fifteen children, only three of whom are now alive. She had easy labours with all, except the last, which was premature at the sixth month. For six weeks after the delivery she had very severe hæmorrhage. Since then she has been very regular as regards catamenia, but during the last week has again had a good deal of hæmorrhage. Last confinement was at end of April, 1877. Before this, she was in the hospital under Dr. Meadows for some complaint of the womb. During her pregnancies she has always suffered from great pain in her right calf, but never in her left. On admission complained of great pain of a dragging, gnawing character, felt all along the back of left thigh and leg, extendiug from hip to ankle. Pain is felt whenever she moves her leg or foot, but not in her knee. She has also a bad headache, and feels very sick. Heart and lung-sounds normal. Bowels costive lately, are generally regular. Appetite bad. Sleeps badly, but not from pain. At a spot about four inches inside great trochanter, and two inches above tuber ischii, great pain is felt on pressure, which shoots down to ankle. She was fired at this spot with a disc heated to 212°, and a blister raised. Ordered Strychniæ gr. $\frac{1}{24}$, Acidi Nitrici ℥ ii, Spi. Chlorof. ℥ vi, Aq. ℥i ter die. Ferri Carb. Saccht. gr. 20 bis die. Conf. Sennæ ℥i ad sedem. 19th.—Cervix uteri is bulky, in normal position, is wide transversely, anterior lip natural, posterior notched and fissured, especially on left; it feels soft and flaccid. Is a well-made person, in good condition, not hyper-excitable, bore the pain of firing well. April 1st.—Quinine gr. v ter die. 11th.—Has still some pain in leg, but is so much better that she wants to go out; has a good deal of brownish discharge from uterus. Blister to left hip, over exit of sciatic nerve. Alum and oak-bark injection. She went out at her own desire on 13th.

Case VI.—M. A. P., aged 25, nurse, admitted April 10th, 1879. Health generally good, looks well and is in fair flesh, has dark hair and eyes, has had no special previous illness. Was taken ill about a month ago with rheumatoid pain in left thigh, knee, leg, and ankle; the pain affected chiefly the front and outer part of leg. Much pain felt when pressure is made between the tuber ischii and the great trochanter, especially at a level a little below the lower edge of glutæus maximus; pain is also felt in popliteal space. Femur moves freely in acetabulum. The pain came on without any apparent cause. Is unable to walk well. Complains that she has had no sleep at night for three weeks. Lungs and heart normal. She had an ulcerated throat two years ago; no skin eruption. She feels week, her appetite is bad. Bowels generally confined, but last three days well open by medicine. Pulse 84, rather weak. Ordered Extr. Nucis Vomicæ gr. $\frac{1}{2}$, Aloes gr. ij in pil. ter die. Pot. Iodidi gr. v, Ammon. Carb. gr. iv, Tr. Cinch. ℥i, Dec. Cinch. ℥i ter die. Morph. Subcut. gr. $\frac{1}{6}$ p. r. n. 16th.—Pain occurs only at times during the day, lasts about one hour; but at night comes on between 7 and 8 p.m., and keeps her awake all night, unless she has an injection of morphia. She is dreadfully thirsty at night, not so much in day. Quinæ Disulph. gr. v, Acid. Sulph. dil. ℥ vi, Tr. Card. Co. ℥ xv, Aq. ℥i ter die. Ferri Carb. Saccht. gr. xxvi bis die. 21st.—Is quite free from pain now, wishes to go out; left in a day or two.

Case VII.—G. A., aged 26. Seen May 16th, 1873. Ill four months. Had first a gonorrhœa followed by a gleet, and then by bubo in left groin, which has disappeared now. Had rheumatoid pains in head and neck for three weeks, since they ceased he has had pains in left

hip and half-way down the back of thigh; he walks lame in consequence. Three years ago he had a bubo in left groin, the ulceration from which extended very widely, and has left cicatrices extending up to sixth or seventh rib, and from near middle line to vertical line of anterior superior spine of ilium. The pain he has now is felt midway between trochanter and tuber ischii, and along back of thigh. Both hip-joints are quite free. The pain in hip disturbs his rest at night. Ferri Carb. Sacch. gr. xx ter die. Subcut. Morphia p. r. n. 21st.—Is much better; can walk to-day without a stick. Last few days has had some red prominent spots, with sero-purulent vesicles at their tops, on his prepuce and glans and near left groin; those on prepuce have dried up, but have left small indurations. 24th.—Much less sharp sciatic pain, but feels low. The eruption has appeared rather copiously on the back, neck, face, and arms; one patch on the arm has quite an annular arrangement. Pulse 90, of fair force. Temperature 98·6°. Pt. c. Pulv. Strychniæ gr. $\frac{1}{20}$, Acid. Nitrici ℥ ii, Sp. Chlorof. ℥ x, Aq. ℥i ter die. By June 11th the sciatica was quite gone from left leg, there was a little in the right; the eruption continued well marked. He was hot and restless at night. 24th.—Trifling sciatica in right leg. Has pain when he gets hot at night in right or left side of chest. Feels much better in himself. A good deal of eruption on legs, more red patches than vesicles; on arms and face it is fading. Pt. c Ol. Morrh. (commenced on 11th), Potass. Iod. gr. v, Ammon. Carb. gr. iii, Tr. Cinch. ℥ss, Dec. Cinch. ℥i ter die. Chloral. gr. xv o. n. July 7th.—More sciatica last three days in right leg; eruption is much less. October 6th.—Is all right except some macular and papular syphilide of the legs. Sciatica all gone except a slight stiffness now and then in right thigh. Pt. c Mist. c gr. viij ad ℥i. Pt. c Oleo. The eruption disappeared slowly; there were still traces of it on January 20th, 1874.

Remarks.—In Case VII. the sciatica was associated with a well-marked syphilide, and was doubtless a co-result of the toxæmia. It is noteworthy that it affected both legs, shifting from one to the other, which is extremely unusual in ordinary sciatica. It was of no great severity, and soon yielded to tonic treatment.

In VI. there was no apparent cause; quinine and iron soon cured. The nocturnal thirst was probably a neurosis like the neuralgia. Brodie relates the case of a lady suffering from thirst where quinine obtained a cure.

In V. the uterus was evidently at fault. It had been hard worked, and on the last occasion when its services were required it became irritable, and failed to bear its burden for the proper time. Its muscular tissue did not duly undergo involution, and its vessels did not contract adequately; so it remained flaccid, enlarged, and congested. The copious hæmorrhage impaired the nervous energy, both generally and locally, and disposed the weak organ to further losses. As the uterine nerves were injuriously affected by all this disorder, they carried to their spinal centre impressions which told unfavourably upon its nerve-cells and on the adjacent nerve-roots of the sciatic; paresis produced its cognate derangement—pain, and sciatica was established. I have recorded a case where severe gastralgia was set up in much the same way. (*Vide Medical Times and Gazette*, 1876, Vol. I., May.) In E. S., quinine in full doses was very beneficial, but the treatment should have been longer continued on account of the great risk of relapses.

In IV. it seemed as if there was some inherited tendency to sciatica, as there was no history of any other neurosis in the family. The disorder was of long duration, getting worse, but yielded to quinine and iron with counter-irritation in less than three weeks.

In V. the consecutive dry rheumatism of knees makes it probable that there was a rheumatic element in the sciatica; and the possibility of getting rid of the pain during its early period by exercise goes to confirm this notion. Hypophosphite and cod-oil benefited him greatly.

In II. the causation seems to have been manifold. His resisting power must have been impaired by the typhoid fever, and subsequently by the night-work, so that he became liable to rheumatoid pain. Probably the gonorrhœa increased this tendency. The hypophosphite and iron enabled him to recuperate his lost energy, and to raise his nerve nutrition to a painless level. Acupuncture seemed helpful.

Case I. was much the most severe and refractory of all, partly on account of the long duration of the malady—ten years—partly from the inveteracy of the morphia habit, which found its justification to a great extent in the relief it afforded to the severe pain. The difficulty of inducing the patient to submit to the privation, and to confide in his adviser, was very great, and at one time success appeared unattainable. Over two months passed away before material improvement was obtained. Had he been a private patient, almost of a certainty he would have sought other and more acceptable counsel at a much earlier period. It would have been better if I had commenced the use of quinine sooner, but the bronchitis claimed attention first, and when that was relieved, I hoped much from phosphorus. Neither it, however, at this time, nor tonga availed anything, nor was acupuncture, though fully tried, of any service. Tonga, I may say in passing, never has succeeded in my hands. The improvement inaugurated by the quinine was subsequently carried on very efficiently by hypophosphite, a drug whose value I cannot doubt, though various good authorities condemn it. Both in phthisis and in neuralgia, I rate it highly, and my experience of it has been pretty large. The absence of knee-jerk in *both* legs, after improvement had commenced is very remarkable, and not altogether easy to account for. I suppose the neuralgic process, deteriorating the nerve nutrition, must have rendered the spinal centre irresponsive to afferent impressions ascending from below, though not to descending volitional; and that this condition diffused itself transversely through the cord. It seems certain that no structural lesion had occurred. Another remarkable phenomenon was the very injurious effect of the second blister to the lower and outer part of the affected leg. There was nothing apparently morbid in the skin, which became so severely ulcerated, but it is certain that its vital power was greatly impaired; and it is impossible not to regard this deterioration as in some way dependent on the prolonged and severe neuralgia. It is well known that such disorder will turn hair grey, and cause other defects of nutrition, so that it is quite probable that it acted similarly in the instance before us. The improvement in this patient's *physique* coincided with an equally marked amendment in his *morale*. From being morose and sullen, he became cheerful and civil. In fact, he was a different being. Often, I fear, we do not make sufficient allowance for the effects of pain. Though pelvic exploration in J. W. detected nothing, it should never be omitted in difficult and refractory cases. It may discover uterine tumour, cancerous or fibroid, impacted scybala, or exostoses, or periostitis.

I am well aware of the very favourable results obtained by the operation of nerve-stretching in various neuralgic disorders, and I am not at all disposed to decry the procedure, but I doubt whether the good effects can be safely assumed to be permanent. It is clear they were not in the present instance, though his subsequent suffering probably led him to depreciate them unjustly. One of the chief lessons to be drawn from the history is the need, *rebus in arduis*, of *perseverance*.

None of the above cases can be ranked as examples of neuritis. Not that it can be affirmed that there was an entire absence of inflammation in all of them. But though a slight amount of *itis* may have been associated with the *algia*, the latter was certainly not dependent on the former. Instances are, however, met with where the reverse obtains, and in these scarification of the sheath of the nerve with the point of a long narrow-bladed knife may be practised with great advantage. Cupping over leech-bites may be better in very recent cases. Dr. Maclachlan relates the case of a poor man reduced to a skeleton, and having all the appearance of a person labouring under malignant disease, who had been suffering severely from sciatica for two months. An obscurely fluctuating colourless swelling was found behind the trochanter major, which, on being opened, gave vent to two or three ounces of pus, with immediate relief, and from that day convalescence ensued. I once adopted this procedure with apparent success, though no pus was evacuated.

A CONTRIBUTION TO THE PATHOLOGY OF HYDRO- AND PYO-SALPINX.[1]

By J. KINGSTON FOWLER, M.A., M.D. Cantab, M.R.C.P.

Assistant Physician and Pathologist to the Middlesex Hospital; Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

In the course of a discussion recently held by the Obstetrical Society of London, on the subject of hydro- and pyo-salpinx, it was remarked by more than one speaker as a curious fact, that if these conditions were so common as some would make out, they should not be met with at the general hospitals. In order to show that such cases are not uncommon, I have thought it worth while to put together the records of fifteen examples, which I have met with in the *post-mortem* room of the Middlesex Hospital, in the course of the last three years.

I do not propose in this communication to describe the symptoms which may arise from the condition, or the relief which may be afforded by the operation for removal of the tubes; on neither of these points have I any experience to place before you. I trust, however, that these omissions will not prevent this side of the question from being discussed by those whose practice brings them in contact with such cases.

I have also omitted to give any clinical details, partly because they are incomplete, as in none of the cases was the presence of the condition suspected during life; partly also from the fact that nearly all the cases were complicated by some other general or uterine disorder, which would render doubtful to what degree any symptoms observed were directly due to the state of the Fallopian tubes, and also because, in most of the cases, the report of the *post-mortem* appearances clearly indicates the course of the disease, and the sequence of the several events, which, together, brought about the patient's death.

At the head of each case I have placed an abstract of the changes found in the various organs, and have given in detail a description of the condition of the parts more immediately concerned.

Case I.—*Retroflexion of the Uterus—Double Pyo-salpinx—Abscess of Left Ovary—Acute Peritonitis.*

Hannah L., aged 29.—There was a large quantity of pus in the pelvic cavity, filling up the posterior *cul de sac*. The pus appeared to ooze from an abscess connected with the left ovary; this was really the dilated end of the left Fallopian tube, which had ruptured into the general cavity of the peritonæum. Both Fallopian tubes were much dilated, and contained pus. The right ovary was twice the normal size, and very vascular. The uterus was bulky, its lining membrane vascular. There were no old adhesions about it. Its posterior wall was deeply grooved, the result of the retroflexion. *Remarks*—In this case the pyo-salpinx appeared to have resulted indirectly from the condition of retroflexion of the uterus.

Case II.—*Hypertrophic Cirrhosis of the Liver—Fibro-myoma of Uterus—Double Hydro-salpinx—Jaundice—Ascites.*

Eliza M., aged 37.—The uterus was large, the cervix sharing in the increased size. A fibroid tumour, the size and shape of an unshelled walnut, was situated beneath the mucous membrane of the posterior wall of the fundus. The uterine mucous membrane was congested. The orifices of the Fallopian tubes were obliterated at both ends, and the tubes considerably dilated. They contained a clear brown fluid.

Case III.—*Fibroid Tumour of the Uterus—Double Pyo-salpinx—Abscesses in Left Ovary—Peritonitis—Pyelitis.*

Elizabeth B., aged 32.—The pelvis was almost filled by a fibroid tumour six inches by three inches, growing from within the right wall of the uterus; the latter had been displaced to the left of the middle line and dragged upwards. Recent inflammatory adhesions bound the structures in the broad ligament to the neighbouring parts on either side. Both Fallopian tubes were dilated to a moderate degree and filled with pus. There were several abscesses containing pus in the left ovary, the right was healthy. *Remarks.*—In these two cases the condition of the tubes was clearly due indirectly to the presence of the fibroid tumour of the uterus.

Case IV.—*Cancer of the Uterus, Vagina, Rectum, and Bladder—Cystitis—Double Hydro-nephrosis—Fibroid Tumour of Uterus—Double Pyo-salpinx—Old Fibroid changes in Right Lung—Renal Cyst (R).*

Selina L., aged 45.—Extensive ulceration and destruction of the upper part of the vagina and lower half of the uterus. The uterus, vagina, and bladder formed a single cavity. The fundus uteri was infiltrated and contained an intramural fibroid the size of a chestnut. Each Fallopian tube was distended to the size of the little finger, and filled with creamy pus; they were adherent to the uterus and closed at both ends. There was no peritonitis. *Remarks.*—In this case, also, the presence of the fibroid tumour may have caused the inflammation of the tubes, as it was situated immediately between their orifices; but the cancer alone was quite sufficient as an exciting cause.

Case V.—*Typhoid Fever—Perforation of Ileum—Aortic, Mitral, and Tricuspid Stenosis—Emphysema—Right Femoral Epiplocele, inflamed, and incarcerated—Local acute Peritonitis—Double Pyo-salpinx.*

Priscilla L., aged 36.—Vagina normal. The uterine cavity contained a small quantity (about ʒii.) of purulent blood-stained fluid. The fundus was dilated. There was an indurated spot at the inner end of each Fallopian tube. Both tubes were dilated to the size of the ordinary calibre of the small intestine (about one inch in diameter), and were adherent to the posterior aspect of the fundus uteri. The fimbriæ were closed. The tubes contained a glairy, semi-purulent-looking fluid. The rectum was normal.

[1] Read before the Medical Society of London, April 28th, 1884.

*

CASE VI.—*Chronic Interstitial Nephritis—Pericarditis Pleurisy—Œdema Glottidis—Pulmonary Œdema—Double Hydro-salpinx.*

Jane L., aged 21.—The fimbriæ of the left Fallopian tube were adherent to the ovary, and both tube and ovary were displaced, lying behind the rectum, where they were firmly held by adhesions to the peritonæum. The tube was distended with glairy, greyish-coloured fluid. The right tube was also distended and had fallen into Douglas' Fossa, its fimbriæ being adherent to the peritonæum. The uterus and vagina contained a quantity of recently effused blood.

CASE VII.—*Scurvy — Extensive Hæmorrhages in the Skin, Mucous Membranes, and various Organs — Double Pyo-salpinx.*

Kate O., aged 34.—The uterus was held in a position of ante-version by bands uniting it to the parietal peritonæum, the fundus being drawn upwards and forwards. The uterine walls were normal. The mucous membrane was injected, and the cavity contained some turbid purulent-looking fluid. The Fallopian tubes were both dilated, forming two sausage-shaped tumours at the back of the uterus, to which, and to the parietal peritonæum, both were adherent. The tubes were closed at both ends, and contained purulent fluid. The walls were thickened. *Remarks.*—In cases Nos. 5 and 7, the pyo-salpinx was the result of endo-metritis. In these cases the condition of the tubes, although a possible source of danger, in no way affected the fatal result.

CASE VIII.—*Cancer of Left Ovary—Secondary Cancer of Uterus and Peritonæum—Cystic Disease of both Ovaries—Dilatation and Elongation of the Left Fallopian Tube — Emphysema — Bronchitis — Secondary Cancerous Nodules in Right Lung.*

M. E. P., aged 54.—The pelvis was filled with a solid cancerous growth involving the left ovary; this was in size about equal to a cocoa-nut. There were also two cysts, one attached to the new growth and one springing from the right ovary, each of these was about equal in size to an orange, and contained clear brown-coloured fluid. The vagina and uterus were displaced toward the right side; the cervix uteri was destroyed by cancerous ulceration, and the upper part of the vagina showed a similar change. The growth in the ovary was adherent to and directly continuous with the cancerous growth in the uterus. The cavity of the uterus was dilated to the size of a large walnut, and was filled with a brownish mucus; the body of the uterus was not infiltrated. The growth in the ovary on section was very soft and contained several mucoid looking patches. The left Fallopian tube was stretched across the front of the growth, measuring thirteen inches in length; the tube became gradually dilated from about five inches from its origin, at the fimbrial end it was the size of a hen's egg. It contained a clear brownish-coloured fluid.

CASE IX.—*Cancer of Splenic Flexure of Colon—Peritonitis—Cancer of Right Ovary—Secondary Nodules in Liver—Double Hydro-salpinx.*

Mary Ann B., aged 43.—There was a tumour of the right ovary the size of a cricket ball, filling up pelvis and slightly adherent to the posterior wall. The uterus was small; it was displaced to the left, and tilted over in the same direction. The cervical canal was dilated and the os internum closed. The left Fallopian tube was dilated to the size of a pigeon's egg; it contained black grumous-looking fluid; its inner end was closed, the fimbriæ were adherent to the parietal peritonæum. The right tube was extremely dilated and spread out upon the surface of the ovarian growth. The growth in the ovary and that in the colon appeared to be entirely distinct. *Remarks*—In these cases (Nos. 8 and 9) the hydro-salpinx was the indirect result of the malignant disease of the ovaries.

CASE X.—*Rupture of the Perinæum—Prolapse of the Uterus—Inflammation and Ulceration of the Vagina and Rectum—Right Pyo-salpinx—Suppuration in Douglas' Pouch and around the Rectum—Cysts in the Left Ovary—Acute Pyelo-nephritis with Chronic Interstitial Nephritis—Amyloid Disease of the Liver and Spleen—Septicæmia—Pneumonia—Parotid Abscess.*

Eliz. A., aged 32.—Emaciated. The perinæum had been ruptured (twelve years previously), the os uteri was situated three-quarters of an inch from the vaginal orifice. All the pelvic organs were firmly adherent to one another. The vaginal walls were inflamed and ulcerated over two areas the size of a sixpenny-piece, from the pressure of the prolapsed uterus. The os and cervix uteri were enlarged, congested, inflamed, and ulcerated on the anterior and upper aspect. The mucous membrane of the uterus was injected; the cavity contained some glairy mucus; the uterine walls thickened and indurated. There was an indurated nodule the size of a hazel nut, containing a small quantity of pus in its interior, situated at the uterine end of the left Fallopian tube, the lumen of which was obliterated. Tracing the Fallopian tube onwards, it became much dilated and sacculated. At this point its contents were of a brownish colour, and purulent in appearance. Still further onward it became dilated to the size of a Tangerine orange, and twisted up on itself. The walls in this portion were much thickened, and covered internally with a greenish-grey membrane, and the contents were purulent and fetid. This sac communicated through an opening, the size of a pea, with another and much larger irregularly-shaped abscess cavity, situated beneath the peritonæum of Douglas' pouch and around the rectum. The rectum was surrounded by the abscess cavity, through which it passed, but without communicating with it. The left ovary contained a cyst as large as a pigeon's egg, filled with clear watery fluid. The ovarian tissue was of a brownish tint, and contained some smaller cysts. The right ovary was converted into an abscess, containing about a drachm of yellow pus. *Remarks.*—In this case the sequence of events appeared to be as follows: First, rupture of the perinæum during labour, then prolapse of the uterus, endo-metritis, and closure of the uterine end of the tube. These changes were followed probably by inflammation of the lining membrane of the tube, closure of the fimbriæ, and accumulation of fluid within it. Adhesions then formed between the lower end of the tube and the peritonæum, followed by ulceration of the peritonæum at the point of adhesion, and escape of the pus into the cellular tissue behind it. As a result of these conditions, amyloid disease and septicæmia ensued.

CASE XI.—*Hypertrophy of the Uterus—Endo-metritis—Double Pyo-salpinx—Rupture of the Left Fallopian Tube—Acute Peritonitis—Cystic Disease of both Ovaries—Syphilis.*

Kate A., aged 46.—There were two pints of pus in the peritonæal cavity. The uterus was equal in size to a large orange; its walls were much thickened, measuring three-quarters to one inch on section. The os externum was closed; the cervical canal was elongated, and contained a quantity of rather fetid smelling and purulent-looking fluid. The uterine mucous membrane was acutely inflamed and covered with a layer of lymph of a greenish tint from decomposition. The openings of the tubes were closed. Both Fallopian tubes were dilated to the size of the thumb, their walls thickened, and their contents purulent and offensive. The left tube was flaccid, and

its lower end was widely opened. The right tube was intact below. Both ovaries were converted into a congeries of cysts containing clear fluid. *Remarks.*—Dr. Hall Davis, under whose care the patient was, was of opinion that the hypertrophy and inflammation of the uterus had probably followed the closure of the os externum, subsequently the tubes had become dilated and inflamed, the rupture of the left tube into the cavity of the peritonæum inducing peritonitis and death.

CASE XII.—*Removal of an Uterine Polypus—Double Pyo-salpinx—General Peritonitis—Pleurisy—Cardiac Thrombosis—End-arteritis—Infarctions in Spleen.*

Eliz. H., aged 41.—The peritonæal cavity contained a pint and a-half of pus. The structures in the pelvis were united together by recently formed adhesions. The vagina was normal. The os uteri was patent; glairy mucus was issuing from it; the cervical canal was dilated and globular, its mucus membrane vascular. From a rough surface within it, the size of a sixpence, a polypus had been recently removed. The cavity of the uterus was slightly enlarged, and contained glairy mucus. A second small vascular polypoid growth was attached close to the orifice of the left Fallopian tube. Both tubes were enormously distended, each measuring two and a-half inches in circumference. They were filled with pus, and their walls much thickened from inflammatory action on both surfaces. The tubes were firmly adherent to the uterus and surrounding structures, and were lying within a sac formed by the uterus in front and the rectum behind, closed in laterally by the pelvic walls and some peritonæal adhesions, and above by some coils of small intestine. An opening, large enough to admit the forefinger, led from this sac into the left Fallopian tube. *Remarks.*—During the operation for the removal of the polypus, the adhesions which then existed between the dilated tube and the peritonæum, the result of a previous attack of peritonitis, had evidently been torn asunder, the result being, that its contents had escaped into the peritonæal cavity, setting up peritonitis, which was the immediate cause of death.

CASE XIII.—*Cancer of the Rectum—Chronic Pleurisy and Pneumonia—Chronic Perihepatitis and Fatty Degeneration of the Liver—General Peritonitis—Peri-rectal and Peri-uterine Abscess—Double Pyo-salpinx.*

Louisa A., aged 41.—There was general peritonitis. A soft cancerous growth occupied five inches of the rectum. Around it, but not communicating with it, were several abscess sacs; in one, formed by peritonæal adhesions between the fundus uteri and the sigmoid flexure, there was a quantity of fetid pus. The upper wall of the sac had given way, allowing its contents to escape into the general cavity of the peritonæum. A second cavity surrounded the uterus, and opened into the vagina by a fistulous channel, situated behind the posterior lip of the os uteri. The uterus contained a small quantity of purulent-looking fluid. The internal orifice of each Fallopian tube was obstructed; both tubes were dilated and formed sausage-shaped tumours which surrounded the ovaries, and were firmly adherent to the posterior surface of the uterus. Both were distended with creamy pus. No distinct connection was discovered between the abscess cavity surrounding the uterus and the Fallopian tubes, or between them and the other sac described. *Remarks.*—Although no direct communication could be found between the dilated tubes and the abscess cavities, the rupture of one of which had produced peritonitis, there can be little doubt that such a connection had at some time existed, and that these were secondary to the disease of the tubes.

CASE XIV.—*Cancer of Uterus—R. Pyo-salpinx—General Peritonitis—Mitral Stenosis—Liver Fatty—Kidneys sacculated.*

Eliza A., aged 39.—The peritonæal sac contained a pint and a-half of turbid yellow pus. The membrane was everywhere acutely inflamed, the change being most marked about the pelvis. Bladder normal. The upper third of the vagina and the cervix uteri were extensively ulcerated. The body and fundus were enlarged, hard, and infiltrated with cancer near the cervix, but not elsewhere. The right Fallopian tube was distended to the size of an ordinary sausage, and contained a quantity of pus. Its walls were considerably thickened; the internal orifice was closed. At the fimbrial extremity the tube had burst into the cavity of the peritonæum. The left tube was normal. *Remarks.*—This case is interesting from the fact that, although the patient was suffering from cancer of the uterus, death was due to peritonitis, the result of the rupture of the dilated tube.

CASE XV.—*Double Pyo-salpinx communicating with Rectum (L) and Ileum (R)—Ulceration of the Rectum Endo-carditis—Amyloid Disease of Liver, Spleen, and Kidneys.*

Harriet T., aged 21.—Extreme emaciation. Some coils of ileum were adherent to the fundus uteri; there were also other peritonæal adhesions, but all of long standing. The uterus was very small, the os was slightly ulcerated, the cervical canal contained glairy mucus. The uterine ends of the tubes were occluded. Each tube was widely dilated, and its walls much thickened. On section, each was found to contain fetid fæcal material. On the left side the distal end of the tube opened into a sac, situated between it and the rectum, and communicating with the rectum through a perforation in its inner wall the size of a sixpence. On the right side the tube communicated with a coil of the ileum, which had become adherent to the right side of the tube and to the fundus uteri. The communication was through a fistulous channel, about one inch long. There were several ulcers on the verge of the anus, but none elsewhere in the intestine. *Remarks.*—The disease of the tubes was in this case undoubtedly indirectly the cause of the patient's death, by inducing amyloid disease and gradual asthenia.

The bare recital of these cases is sufficient to establish the fact, which has been doubted by many, that this condition is a very real one, and by no means free from danger. It is very probable that many cases of peritonitis which have been regarded as idiopathic, as secondary to abscess of the ovary, or pelvic cellulitis, have been really due to rupture of a Fallopian tube, distended with pus, into the general cavity of the peritonæum.

It will be seen that the state of the tubes was the immediate cause of death, in eight cases out of the fifteen; all these were cases of pyo-salpinx. In six, the affection was bilateral, in two it was limited to the right side.

Of the eleven cases of pyo-salpinx, death was due to peritonitis in seven (one of these, however, was from perforation of the intestine, in a case of enteric fever), and in one case each to septicæmia, amyloid disease, cancer of the uterus, and scurvy.

In nine cases of pyo-salpinx, and three of hydro-salpinx, there were old adhesions between the tubes and uterus, or other structures in the pelvis. In two cases of pyo-salpinx, the adhesions were recent, and in one case of hydro-salpinx there were no adhesions.

There can be no doubt that any inflammatory condition of the uterine mucous membrane, however induced, it may be by extension of a vaginitis or some affection of the os or cervix uteri, by a retroflexion, by

the presence of a fibroid tumour or polypus, or as a result of prolapse or malignant disease, may spread to the Fallopian tubes, and ultimately establish the condition of pyo-salpinx.

It is probable, also, that in some cases the primary origin of the disease may be tubercular, but of this I have not met with any instance.

In many cases I have noticed that there is an induration close to the uterine end of the tube, the lumen of which is at that point entirely obliterated.

The fimbriæ and the tubes themselves are usually adherent to the uterus or some other structure in the pelvis; in chronic cases of pyo-salpinx these adhesions are generally firm, but in the earlier stages, when an operation for the removal of the tubes is possible, these adhesions have not been found by Mr. Lawson Tait, and others who have performed such operations, to present greater difficulties in their management than those commonly found in cases of ovarian tumour. It is to be hoped that as a result of the increased attention which is now, mainly through the writings of Mr. Lawson Tait, being directed to this condition, a clearer light will be thrown upon its pathology, for this must ever remain the only sure guide to accurate diagnosis and rational treatment.

THE LOCAL DISTRIBUTION AND ÆTIOLOGY OF ERYTHEMA NODOSUM.[1]

By HENRY HANDFORD, M.D.

I WILL commence what I have to say on the subject of erythema nodosum, by describing a case that came under my notice in October, 1883; not because it contains anything new or unusual, but because it illustrates in a remarkable manner several points in connection with the *local distribution*, ætiology, prognosis and treatment, to which I wish to draw attention.

Case.—A. B., a girl, aged 17 years 11 months, was seen by me on October 30th, 1883, and was complaining of a general feeling of illness, with headache and painful swellings on both legs. I found that there were lumps, varying in size, from a pea up to nearly half a lemon, and in colour, from a bright scarlet to a dusky red, on both shins. One lump was of a very dark red, almost livid colour, rather soft, and, in fact, giving an indistinct impression of fluctuation. The node was evidently greatly inflamed by much standing and walking. All the lumps or nodes were tender on pressure, and the patient complained of a feeling of burning and itching in them. There were several small lumps, nearly circular in shape, and about equal in size to half a Barcelona nut. They were evidently in the skin—for they moved freely over the fascia—and were situated all around the patella, and the sides of the knee; but not over the patella or in the popliteal space. A few nodes were found as far as half-way up the thigh, on the front and outer aspect of the limb. There were one or two on each arm over the ulna, and a few over the triceps. There was one small node on the lobule of the left ear. There were none on the trunk, hands, feet, or ankles; *and none on the flexor surfaces of the arms or legs.*

The lumps first began to make their appearance about a week before I saw her. She was of average height, but rather thin; of fair complexion, and with a clear, transparent skin. She had never had rheumatism. She had scarlatina as a child, but no other serious illness. She was rather anæmic. Bowels regular; menses regular; tongue coated with a thin white fur. Temperature 99·4° Fah.

She was treated by rest in bed, and the application of lint dipped in boracic lotion (a cold saturated solution of boracic acid in water) to the most painful lumps:—the lint to be moistened with the lotion frequently. Internally, she took six grains of the citrate of iron and quinine in one ounce of water, thrice daily.

Next day she expressed herself as feeling much better: the tongue was clean, and the temperature normal. I ascertained that she was very subject to chilblains in winter, and had habitually cold hands and feet; and I noticed that the nails were very blue. The cardiac sounds were normal. By the end of the week she was convalescent, the nodes having disappeared, only leaving a little discolouration behind, and all pain was gone.

The local distribution of erythema nodosum is very precise. It is generally described as occurring "on the fore part of the legs, sometimes on the arms." What I wish to point out is, that on the limbs it is strictly *limited to the extensor surfaces.* It occurs occasionally on the face, and still more rarely on the trunk. And not only is it confined to the extensor surfaces, but it is practically limited in the lower extremity to the region of the tibia, the lateral surfaces of the knee, and the anterior and outer surface of the thigh in its lower half. I have not seen a node on the foot or ankle. In the upper extremity the nodes are to be met with chiefly over the ulna, almost or quite as far as the wrist. I have never seen it affect the hands or fingers. Above the elbow it extends nearly to the shoulder on the outer and posterior surfaces, chiefly, however, over the triceps. Many nodes occur close to the elbow, as in the lower extremity they cluster round the knee. The nodes near the elbow and knee are generally small. The largest and most typical ones occur about the middle of the leg over the tibia. They are less frequent on the fibular side.

Ætiology.—Beyond the fact that erythema nodosum occurs chiefly in young subjects, between the fourth and the twentieth years, is more frequent in females than in males, and generally affects feeble and anæmic individuals, little definite is known. A connection with rheumatism also seems to have been established.

The great similarity between erythema nodosum and chilblains, in almost everything except their local distribution, and the fact that chilblains sometimes slough, and that, so far as I am aware, the nodes of erythema nodosum never either suppurate or slough, points to a similarity in their ætiology.

I take it that both of them consist in a local slight inflammation, with exudation of liquor sanguinis into the cutis vera; diapedesis of white corpuscles and proliferation of connective tissue corpuscles. There is also in erythema nodosum a rupture of blood-vessels and more or less extravasation of blood, as shown by the play of colours which surround the nodes in the later stages. There are pain, heat, redness and swelling. The pain is accompanied in both by a characteristic itching and burning, and a feeling of tension. The redness is frequently somewhat dusky. They both are supposed to occur specially in persons subject to rheumatism, and in individuals with a feeble circulation and lax tissues. The cause of chilblains I conceive to be essentially *cold*, associated either with pressure impeding an already imperfect circulation, or with occasional exposure to too great artificial heat, especially immediately after exposure to cold.

The *exciting causes of erythema nodosum*, which determine its localisation, I believe to be chiefly *cold*, an *imperfect local circulation*, and slight and trivial *injuries.*

[1] Read before the Nottingham Medico-Chirurgical Society, March 28th, 1884.

These causes would explain the limitation of the nodes to the extensor surfaces.

I may mention, in passing, that chilblains also occur chiefly, I believe, on the extensor surfaces.

The extensor surfaces of the arms and legs are much more exposed to slight injuries, and much less perfectly cushioned with fat and muscles, than the flexor surfaces. It is well known what extremely slight causes produce a contusion with rupture of blood-vessels and extravasation of blood in certain individuals with specially lax tissues and delicate, friable vessels. The slightest touch almost will be followed in a few hours by the blue mark of a bruise, and the imprint of the fingers may be left by grasping the arm. Now, a node of erythema nodosum is little more than a bruise, with slight inflammatory re-action and exudation superadded.

The play of colours noticed in the progress of a node of erythema nodosum, from day to day, has long drawn attention to the resemblance to a bruise, and has caused the name "dermatitis contusiformis" to be given to it. (Neumann, Hautkrankheiten. Vierte Auflage, p. 170).

There can be no doubt that the play of colours is due to extravasation of blood, the only question remaining being whether that extravasation is the cause or the consequence of the local inflammation.

Again, in a very closely allied disease, nettle-rash, or erythema urticans, there can be no doubt that local irritation, *i.e.*, a slight local injury, can determine the site of the eruption. One has only to run the finger-nail sharply across the skin, when the wheals have all disappeared, to bring them out again in the course of a few minutes or half-an-hour, wherever the finger has irritated the skin.

The parts that I may call the seats of election of erythema nodosum, viz., the skin over the tibia and extensor surfaces of the knee and elbow, have a less perfect circulation than the skin of the rest of the limbs, for the following reasons. During a majority of the 24 hours, the knees and elbows are in a state of partial flexion. The skin over them is then stretched, the vessels slightly compressed, and the circulation not so free as when the joint is extended and the skin lax. The skin over the tibia and over the ulna appears, too, to be in a state of greater tension than the skin over the muscles; and, further, the amount of subcutaneous cellular tissue, from which the skin receives its blood supply, is much less over the tibia and ulna and on the extensor surfaces, than over the muscles and on the flexor surfaces; and hence we should expect the skin on the extensor surfaces not to be so well nourished, and not to have such an active circulation as that on the flexor surfaces.

The greater frequency of erythema nodosum on the legs than on the arms would be explained by the fact that the legs are more exposed to injuries, and to cold, and that the circulation in the legs, especially in the upright position, is much less active than in the arms. The freedom of the skin of the trunk from erythema nodosum is probably due to its free circulation and its greater warmth; the latter condition being caused by a greater amount of clothing being generally applied to it than to the legs, and by its being supplied with heat by conduction from the warmer internal organs.

The comparative freedom of the face is to be explained by its extremely active circulation.

It has been noticed that many of the nodes are oval in shape, and that their long axis corresponds with that of the limbs. This can be seen over the tibia and ulna, but seldom anywhere else. I cannot help thinking that this oval shape has been made too much of, with a view of connecting the nodes of erythema nodosum with the periosteum of the long bones over which they occur, especially in cases with a rheumatic history. This view, however, is quite untenable, for the exudation is in the cutis vera, as may be shown by the nodes being quite movable; and, moreover, the nodes often occur in parts quite distant from any periosteum.

The oval shape, with the long axis in that of the limb, I believe to be due to the fact that the skin of the limb, owing to its greater length than breadth, stretches more readily in its long axis than in its transverse.

The *prognosis* is always good. In the case I have related above, the larger node on the leg was supposed to be going to suppurate, and it looked so angry that had I not known that the nodes of erythema nodosum never (?) suppurate, I might have shared in the opinion.

As regards *treatment*, the pain and itching are readily relieved by the *horizontal position*, and by *cold wet applications:* plain lint dipped in boracic lotion (*i.e.*, a cold saturated solution of boracic acid in water), and allowed to cool the part by evaporation, being as good as anything. In the few cases where cold applications are not well borne, warm fomentations will readily give relief. Of medicines, iron is the most important, combined with quinine, arsenic, or strychnia.

THE PSYCHICAL RESEARCH SOCIETY.

By SAMUEL WILKS, M.D., F.R.S.

I SEE no prospect of any speedy solution of the questions in which the Psychical Research Society is engaged, or at least such a solution as will satisfy all minds, since the methods it employs and the sentiments it expresses about the ordinary phenomena of life are so widely different from those adopted and held by ordinary scientific men. There seems no common ground upon which those who are engaged in the discovery of the truths of Nature, and the members of this Society, can work together. Of course I cannot speak for all, but having read much of the literature of those who are called spiritualists, and of those who believe in thought-reading, clairvoyance, and kindred phenomena, I find that many of the most eminent of them do not admit the necessity of assenting to the facts which are generally supposed to be substantiated in many branches of science; they apparently ignore such ideas as laws of Nature, and seem to deny that we have any insight into cause and effect. Once having put themselves into this frame of mind, they are ready to accept the truth of any occurrence, however remarkable it may seem to those who follow the ordinary scientific methods. Thus many of the contributors to the spiritualistic magazines, when about to relate some circumstance which to the mass of mankind would be incredible, never fail to add, "scientific men declare this *must* be so, and that *cannot* be," &c., &c.

Some of the most distinguished spiritualists and believers in thought-reading express themselves much in this manner; for example, men so eminent in their respective positions as Mr. Wallace and Professor Sidgwick. The former in his work on "Miracles and Modern Spiritualism," attempts to refute Hume's well-known argument against miracles as being violations of the laws of Nature and opposed to experience, by saying, "Such a simple fact as the existence of a flying fish could never be proved if Hume's argument is a good one, for the first man who saw and described one would have the universal experience against him that fish do not fly or make any approach to flying, and his evidence being rejected, the same argument would

apply to the second and to every subsequent witness, and thus no man at the present day who has not seen a flying fish alive and actually flying ought to believe that such things exist." It seems very difficult to understand how Mr. Wallace could make use of such an obviously weak objection; one would have thought that so good a student of natural history would have believed that every part of the animal body had its uses, and that every function had its corresponding organ. Mr. Wallace surely does not mean to maintain that a fish, as usually understood, and about which he maintains that an erroneous assertion was made, really can fly; he can only mean that it would have been wrong to deny that a fish might be found with so largely developed fins as to enable it to spring from the water and for a time fly through the air. This is a totally different proposition, and in no way touches Hume's argument. But however fallacious this reasoning, the object of the illustration is clear, that we cannot speak positively of the laws of Nature; that we cannot argue from cause to effect, and *vice versâ*, but ought to be prepared to accept the truth of any occurrence which is told us, however remarkable it may at first sight seem. Mr. Wallace's argument about flying fishes would hold equally good of horses and men. I apprehend, therefore, that if he were told that a horse was seen flying through the air, his proper state of mind would not be that of incredulity, but a readiness to believe it on evidence. If he were informed that human beings had taken to flight, his attitude of mind should be the same—quite open to receive new facts, with a strong conviction that we have not arrived at that height of knowledge that we could yet assert anything about cause and effect in Nature.

If the newspaper reports are correct, Professor Sidgwick propounded exactly the same doctrines at the London Institution. I apprehend he found it also necessary to deny any order in Nature, and to assume at the very outset of his lecture that it was all a chaos before he could dwell upon the remarkable occurrences he was about to relate. In order to prepare his audience, he began by assuming the very point he wished to prove; he told them that there were no laws and no order in Nature—that after a million events of a like kind had occurred something of a totally different character might then turn up. In fact, we could predict nothing. He put a million black balls in a bag and one white one; the latter he did not draw until the whole of the others had passed. He obtained the assent of his hearers to the acknowledgment that every one would have bet upon the millionth and one ball being also black. He had then to inform them that their logic and conclusions would have been wrong, that the Ruler of the world is capricious, His acts arbitrary, He has no laws, and therefore that anything odd may turn up at any time. If the Professor made them believe that his illustration was good, he must have had an easy time of it for the rest of the evening. He might possibly have said that it were wrong to convict one man of poisoning another on any chemical evidence; for, although the analyst had in many thousand instances obtained the same reactions, it is possible that on the last occasion totally different qualities and colours in his tests might appear.

One may forgive Mr. Ruskin in the poetry of his language for declaiming against the stupidity of scientific men for supposing that the rain must always come from previously existent vapour, but it does seem very remarkable that two gentlemen who have apparently given the subject a study, should be able to suggest to their audience such a possibility as the next rainbow they see being turned upside down, and the colours of the spectrum altogether altered. The fact is that there is nothing in Nature like the Professor's illustration of the balls in a bag, and this makes it very suggestive as to the value of the researches of his Society, that he should require at the very outset of an investigation a disbelief in the order of Nature, and apparently a belief in an effect without a cause. Both Mr. Wallace and Professor Sidgwick say to scientific men, as was formerly said to Faraday, it is of no use for you to join us in our investigations until you get rid of your present beliefs and so-called scientific methods.

This is literally true, as may be seen by the mode which is recommended by believers for the investigation of spiritualistic phenomena. First of all I must speak of the well-known methods recommended to students of Nature for the discovery of truth. From Bacon to Herschel all natural philosophers have been in accord—that certain "idols" should be discarded, that all work should be done in a "siccum lumen," that the student be alone and quiet in his laboratory, with no disturbing noises about him to conflict with his operations (no street music), no one present to converse with him, that he should be most intent upon his research, not too ready to jump at conclusions, but having a hesitating and sceptical state of mind.

Now we will see what the method is which is recommended by a well-known spiritualistic leader, designating himself "M.A., Oxon," for the investigation of facts in which he is interested:—"A circle should be formed of six or eight persons, half men and half women; they should sit down in a subdued light and place their hands on the table. They must not concentrate their minds too fixedly on any expected manifestation; they must engage in cheerful conversation and avoid dispute and scepticism; music is also a great help," and so on. It is obvious that if any inquirer into the truths of Nature is impressed with the absolute necessity of following the rules enforced by Bacon and others, he is bound to discard any results obtained under such opposite conditions as those last laid down. If he did attend a *séance* he would be forced to admit that the results observed were quite untrustworthy, and thus no advance would be made in the spread of their truth.

If, therefore, the methods propounded for the investigation of these phenomena are such as those who are engaged in the study of natural events consider open to grave objections, and if, at the same time, the spiritualists deny the correctness of the conclusions which men of science arrive at in the material world, there seems no reasonable prospect of any satisfactory agreement being arrived at. The spiritualist and scientist will each have to follow his own course, each denying the other's conclusion, there being at present a great gulf between them.

Medical Times and Gazette.

SATURDAY, MAY 3, 1884.

On Wednesday afternoon the House of Commons refused, by 149 to 79 votes, to allow Dr. Cameron's Bill for the Regulation of Cremation and other modes of disposal of the dead to be read a second time. Dr. Cameron's speech in favour of the measure was very moderate in tone as well as very able, but he relied rather too much on the imperfections of the present burial laws. They are unquestionably very imperfect, and the first part of his Bill, which would provide that no body shall be buried without the production of a medical certificate of the cause of death, would be accepted as a most desirable reform. But it furnishes no argument in favour of cremation. The tone of the debate was not on the whole quite worthy of an important legislative body in the last quarter of the nineteenth century. The present Home Secretary and the Home Secretary of the last Government, both treated the question really at issue rather cavalierly; and while admitting the grave imperfections of our burial laws, the former gave no hint even that the Government have any idea of amending them. Sir Lyon Playfair was too scientific and somewhat too much of the professor to please our average legislator; and the care and intelligence with which the Bill had been read by some of the members of the House was shown by the declaration of one of them, that "the Bill was simply a measure designed to put five shillings into the pockets of the medical profession every time a person died." The subject is one that demands very full and careful discussion; but Dr. Cameron may feel well satisfied that his measure, imperfect as it is, was supported by a very respectable number of votes.

On Tuesday last Mr. Gibson gave notice in the House of Commons that on May 27th he would call the attention of the House to the state of the Indian Medical Service, and would move a resolution.

Dr. Cayley, at the Medical Society on Monday last, read notes of an interesting and unusual case of so-called ulcerative endocarditis. The disease ran its course in about eight days, supervening on old rheumatic heart disease. Dr. Heneage Gibbes had examined the organs microscopically for micrococci, and found abundant evidence of their presence. Dr. Cayley was unable to account for their mode of entrance into the body, as the man had not been subjected to any known source of contagion. He discussed the significance of micro-organisms in these cases: they must have been present within the body, but probably had only become operative when the patient's health began to give way, and his tissues were no longer able to resist their septic effects. He considered the term "ulcerative" as inappropriate for many cases, as also for his own, because there was no ulceration present. There was often difficulty in diagnosing such cases from typhoid fever, as the temperature curve much resembled that found in the latter disease. Dr. Green rather ridiculed the idea of such cases being mistaken for typhoid. He seemed to argue that the micro-organisms were the essential cause of the disease. Dr. Coupland, it will be remembered, contributed to our columns, about two years ago, some very well marked cases, with temperature curves, which he considered almost characteristic of the septic form of the disease. The subject is one of great interest to physicians, surgeons, and pathologists alike; apart from the difficulties of diagnosis, there is also the still more obscure question as to the mode of entrance into the body of the micro-organisms which add so much to the danger of the disease. How do they find entrance to the endocardium, and why, as an initial lesion, do they commence operations by attacking the vegetations found on certain diseased valves? The full significance of these germs can only be determined by carefully conducted inoculation experiments. Meanwhile, in suspected cases, in cases of old heart disease in which acute septic symptoms suddenly come on, let a wary diagnosis be given. A paper was subsequently read by Dr. Kingston Fowler on the pathology of Hydro- and Pyo-salpinx, which will be found in full in another column.

The attention of the Clinical Society, at its meeting on April 25th, was entirely occupied by surgical questions. In describing an operation performed by him for extensive malignant disease of the tongue and soft palate, Mr. Gant took occasion to review the relative merits of the various operations at present practised for removal of disease within the mouth, giving preference in almost every respect to that known as the buccal operation. A paper by Mr. G. R. Turner, on a case of Gluteal Aneurysm, operated upon by him in the Seamen's Hospital, gave rise to a discussion, in the course of which, the efficiency of Davy's rectal lever for controlling hæmorrhage, was endorsed in terms of high praise. The rarity of gluteal aneurysms, whether as the result of direct injury, or of diseased vessels, is well recognised, but Mr. Turner's case, and the experience gained in the course of the treatment which he adopted, will be a valuable guide to future action in cases of a similar kind.

Another uncommon injury, requiring special treatment, was described in a paper by Dr. Lediard, of Carlisle. Fracture of the coronoid process, accompanying dislocation of both bones of the forearm, is mentioned in many of the leading surgical text-books as an occurrence of great rarity; although from the experience of Dr. Lediard himself, and that of other surgeons who took part in the debate, it would appear to have come under observation more frequently of late years. An interesting case of recurrent thrombosis of some of the great veins of the arm, following fracture of the radius and ulna, was read by Mr. Arbuthnot Lane.

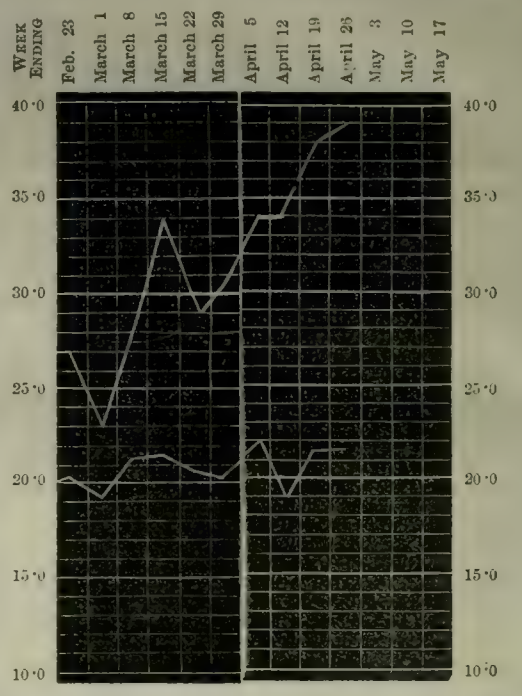
A very large vote was given at the Oxford Convocation on Tuesday last, when the new statute, for admitting women to some of the honour examinations for men, was brought forward. The triumphant

passing of this statute by a majority consisting of 464 voters (321 voting on the other side), was perhaps a little more than was sanguinely expected by the promoters of the measure. But intellectual evolution is surely showing itself even in Oxford Convocation, and there seems to be some reason to believe, when this present decision and the recent vote on the grant to the physiological laboratories are taken into consideration, that the charge of obscurantism and systematic obstruction to reasonable measures of progress will no longer fairly lie against this hitherto somewhat slavish body. The Warden of Keble has done himself and his university credit, by the influence he has exerted in contributing to the passing of the statute—an influence which, though unaided by public oratory, was perhaps no less important than the admirable and trenchant speech he delivered on the question of the physiological grant, which men of science and medicine should gratefully remember. It is not to be doubted that the Warden of Keble secured several votes which would otherwise have been given at the behest of Canon Liddon, who headed the opposition to the statute. The majority of Tuesday was also largely owing to a better organization than heretofore of the progressive party in Oxford, and the unremitting labours of the London Committee formed to protect the statute. The result of the vote is, as we have already stated, to put the women students at Oxford on a similar footing to their colleagues at Cambridge; and to give them a *testamur* of real and marketable value.

We much regret to record that Dr. Andrew Whyte Barclay died, at his residence, Whitney Wood, on the 28th inst., after a few days' illness, at the age of 66 years. Dr. Barclay, who was an able and highly cultured man, was for many years Physician to St. George's Hospital, and when in 1882 he became Consulting Physician to that charity, he retired from the active practice of his profession. He continued, however, to discharge the duties of the important post of Medical Officer of Health for Chelsea, to which he was appointed many years ago. And it seems but a few months since he was elected Treasurer of the Royal College of Physicians, adding one more to the many ways and offices in which he had for so many years rendered good and faithful service to the College. His death will be greatly regretted by a wide-spread circle of friends.

A case, which reminds one of the arrangement by which the schooling of Master Dobbin in "Vanity Fair" was paid for, came before Mr. Justice Stephen on Monday. Dr. Bryant, of Sussex Square, sued a butcher at Twyford for 228*l.*, for medical attendance on his sister, and the butcher presented a claim for meat supplied to Dr. Bryant. The plaintiff stated that the defendant had agreed to supply him with meat, to be set off against the plaintiff's professional charges, and this agreement was accepted as valid by the jury. In another respect the jury's decision was not so favourable to Dr. Bryant, for they found that three guineas was not a reasonable charge for a journey of seventeen miles, occupying four hours, and allowed only one guinea for each of such visits. Juries are, however, never very reasonable in their views about reasonable charges. Five shillings and threepence an hour is not a reasonable payment for a doctor's services.

The weekly number of deaths in London, which we are accustomed to see falling considerably short of the ten years' average, was last week only 19 below that average; while, curiously enough, the births, which



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of last quarter, and the first four weeks of the present quarter.

of late have usually fallen short of the ten years' average by more than 100, were last week as many as nine in excess of it. Zymotic diseases still continued very fatal, the deaths from them, 300, being 64 above the average, and the zymotic rate reaching a higher point than it has yet touched this year. The small-pox epidemic still extends, and on Saturday last the number of patients lodged by the Asylums District Board reached 450. In spite of this the deaths from the disease last week only numbered 12. The deaths from whooping cough were fewer than in the previous week, but those from measles underwent an increase. The number of fatal cases of the two diseases were 81 in excess of the ten years' average. The deaths from respiratory diseases numbered 327, and were 61 below the average. We ought now to have a series of favourable returns until the diarrhœa season sets in.

Mr. Vincent Richards, we are told, has been successful in communicating cholera to animals, and has discovered "that choleraic alvine discharges contain a virulent poison, which seems to be of the nature of a chemical compound, and not of an

organism." When will the public, and indeed a large portion of the profession, acquire a little more of the true scientific spirit and practice of the inductive method? They would then see that Mr. Richards' results, should they be verified, in no way invalidate the conclusions at which Dr. Koch has arrived, and that the connection which he conceives to exist between the bacillus and the collective phenomena, known as cholera, is what Mill expresses when he describes the phenomenon which is constantly present or absent in certain groups of phenomena, agreeing or differing in nothing else, as "the effect, or the cause, or a necessary part of the cause of the similarity or diversity of the general result." In the present enquiry he would doubtless admit that the immediate cause of the symptoms may be an organic poison generated by the bacilli, and by them alone. If Mr. Richards has proved this, and, still more, if he or others can succeed in isolating it, so far from disproving the bacillar theory, they will perhaps have laid the keystone to the arch so cautiously built up by the German Commissioners.

Bacilli of other kinds secrete, generate, or in some way bring about the formation of special organic products in the cultivating fluid, just as the torula induces alcoholic fermentation in saccharine solutions. Alcohol is the immediate cause of intoxication, but the yeast plant is an equally necessary link in the chain of cause and effect. That some species, at least, of bacilli do produce effects closely analogous to those of the living ferments is clear from the phenomena of ordinary putrefaction, for which the presence of *B. subtilis* is absolutely essential; and it is remarkable, that while Buchner showed that the putrescence of a fluid was fatal to the *B. anthracis* and *fœni*, which disappeared as the *B. subtilis* multiplied, Koch has observed that putrefaction destroys the vitality of the bacillus identified by himself. If we admit the existence of a material cholera poison at all, we must allow it to be capable of self-multiplication—between this and the hypothesis of dynamic or immaterial agencies there is no *tertius locus standi*—and a chemical compound cannot be conceived of as such. A poison, capable of self-multiplication, must either be itself living, or be the product of a living and multiplying agent. Richards' discovery, if such it be, is precisely what Koch's would lead us to expect, and it is a pity that he should seek to magnify its importance by representing it as contradicting the conclusions of his forerunner. Koch very wisely deprecated the drawing of any conclusions from the negative results of his inoculation experiments, since few, if any, human infectious diseases, small-pox excepted, have been proved communicable to the lower animals; but the alleged successes of such trustworthy observers as Thiersch and Burdon Sanderson give good grounds for believing that when the necessary conditions are, whether by chance or by calculation, fulfilled, attempts at inoculating cholera may also be successful. Perhaps Koch busied himself too exclusively with the bacilli, in which case he might expect no better result than if, to revert to our analogy, he had attempted to make a man drunk on German yeast.

The Portsmouth correspondent of *The Globe* telegraphed on Tuesday, "Some sensation was caused shortly after eleven this morning, when the troopship *Crocodile*, from Bombay, with several hundred troops, arrived at Spithead, flying the yellow flag. It was known that she had cholera on board, and communication with her is now prohibited. She has anchored at Spithead to await the visit of the medical officer, who will decide whether she is to go to Motherbank and be subject to quarantine regulations." If this be correct, is it a case of importation, or is an "epidemic constitution" hovering over our shores?

Theophilus Taylor, a well-known West-End practitioner, died suddenly last week at the age of 60. Born and bred in a cathedral city, he received his medical education at University College, and Dr. C. J. B Williams mentions him in his "Memoirs" as one of his successful pupils. He was a man of kind and gentle nature, of the strictest integrity and uprightness, and of good abilities, highly esteemed by his brother practitioners, and held in affectionate regard by his patients. We are often apt to forget how much the favourable idea which, on the whole, the public has of the profession, depends on generalisations founded on such particular instances.

A Bill for the Regulation of Medical Practice in France is now under the consideration of a committee of the Chamber of Deputies, and the measure has arrived at the stage which relates to the practice of medicine in France by individuals who are only furnished with foreign diplomas. The *Union Médicale* states that for a long time past the medical profession has desired that the power of the authorities to confer a right to practise upon foreigners should be abolished, and that such right should only be obtainable by undergoing examination before a Faculty of Medicine. In this way the advent into the large cities of France of foreign medical adventurers, which is now not unfrequent, would be prevented. The *Union*, however, regrets to learn that some of the medical deputies are not favourable to this course, and are using their influence with the Minister of Foreign Affairs to induce him to enter into negotiations with the various foreign governments in order to obtain a reciprocity of practice in favour of Frenchmen in other countries and of the natives of such countries in France. The writer looks with dread upon the idea of the diplomas which are manufactured in America or in Europe (especially in *outre Rhin*) obtaining currency in France, and can only conjecture that such a project must be favoured by those who, fearing themselves to become future victims of civil discords, or *coups d'état*, are anxious to secure to themselves the power of practising elsewhere than in their own country. It is to be hoped, he adds, in the name of patriotism, justice, and the interest of the country at large, that such attempts will not get beyond the lobbies in which they are hatched; and that a measure which contains some needed items of reform will not be sacrificed to personal interest.

At a time when the British Government is proposing to introduce a liberal reciprocity scheme, it is disappointing to find our neighbours clamouring for protection. One would have expected that France, at least, with its highly educated practitioners, would have been able to regard with equanimity a free trade in diplomas, secured from abuse by reciprocity. If the measure demanded by the *Union Médicale* were passed and strictly carried out, it would bear especially hard on English practitioners, who may wish in future to practise amongst their countrymen in the southern health resorts. One advantage, however, may result from the prospect of such legislation. It will be a caution to those who are grumbling at our own reciprocity proposals, and endeavouring to raise the trades-union spirit against them.

This being the twenty-fifth year since its foundation, the French Medical Association recently held its jubilee meeting, under the genial presidency of M. Henri Roger. It does not concern itself with medical science, and at its meetings enters into no discussions on the subject, but confines its attention to benevolent objects regarding the profession, and to the support of the rights and interests not only of its own members but of the medical profession at large, being always ready to tender counsel and aid when these are endangered. Consisting of several thousand members, distributed among local societies throughout France, and united for action in the central society in Paris, it now constitutes a powerful organisation. It is also prosperous in its pecuniary resources, being in the possession of 1,863,000 francs (828,655 francs of which constitutes its pension fund), and counting an increase of 110,000 francs upon the preceding year. During the year which has just closed, 80,000 francs were distributed among pensioners, their widows and children, or bestowed on necessitous strangers.

The *Alliance Française*, of whose formation we gave some account several weeks back, has now issued its programme, and having formed its organizing committee, only awaits a sufficient number of subscribers to commence vigorous operations. It has fixed six francs as the minimum subscription, in order that no well-wisher of the project may be deterred on the ground of expense. And this project is a very up-hill one, and will want a good deal of money to set it afloat. It aims at no less than arresting the decline of the propagation of the French language, and the only means it can suggest is the establishment of schools and normal schools, wherever French influence extends in the colonies or foreign possessions. It proposes to commence operations in the Basin of the Mediterranean, where the possession of Algeria, the suzerainty of Tunis, and the traditional French influence throughout the Levant are supposed to furnish a promising field for the contemplated propagation of the language.

Professor Alphonse Milne Edwards laid before the *Académie des Sciences*, at its last meeting, a photograph of the young gorilla which has just died at the Jardin des Plantes. This little animal was the first representative of the genus gorilla that had ever been seen alive in Paris, this variety of anthropoid ape having been hitherto known only from descriptions of travellers and from the anatomical remains of individuals killed by the natives. Professor Milne Edwards gave an account of the habits of the gorilla, and of its savage untamable disposition, which, up to the present time, has rendered its education impossible. The intelligence of this ape, the largest and most formidable of all known species, is very far below that of other anthropoids, such as the chimpanzee or the gibbon.

Dr. Bertillon, in his weekly report on the mortality of Paris (*Union Médicale*, April 22nd) observes that a service which has been established there is calculated to be of the highest utility if the public were made better acquainted with its existence. Any person, the subject of an epidemic, contagious, or parasitic disease, may be transported gratuitously to a hospital by application to any police-station. The request is immediately telegraphed to the central service, and a vehicle is dispatched at once, the horses being kept ready harnessed. The carriages so used are constructed especially for the sick, and are thoroughly disinfected and warmed, and a relative is allowed to accompany the patient. It is much to be regretted that these arrangements, so well calculated to be of use to the sick poor, are not better known. A great number of such patients are at present transported in the public conveyances, causing a very inconvenient demand on their scanty means, and endangering the public health.

The discovery of micrococci in the sputa and tissues, in cases of acute pneumonia, has had the not unnatural effect of awakening the dormant controversy as to the infectious nature of the disease itself. The peculiarly sudden onset, the localisation of the principal lesion, the course and decline of the fever within definite limits, have always inclined the clinical observer to regard the whole process as analogous to that of some of the specific fevers. The effects of chill, however, have hitherto been credited with a large share in the causation of the malady, and especially in the persons of otherwise healthy and robust patients. A paper by Dr. Jürgensen of Tübingen, read last week at the Medical Congress in Berlin, attacks these latter points in the ætiology of pneumonia, with the aid of convincing statistics, and, following lines of investigation similar to those employed in the study of typhoid fever, goes far to prove that meteorological conditions, and especially degrees of dampness, exercise a powerful influence on the frequency and severity of the disease. Facts as to absolute contagion are wanting, but sufficient evidence has now been adduced to warrant the treatment of acute pneumonia as a specific fever, and the adoption of prophylactic measures in any locality where it may be prevalent.

A practical demonstration in support of his views on cerebral localisation, was presented to the same Congress by Professor Goltz, of Strasburg. A dog, from whose brain he had removed a considerable por-

tion of the cortex, assumed to contain centres for controlling certain movements, gave lively evidence that its powers of movement and sensation continued unimpaired, and that sufficient intelligence remained to enable it to resent effectually any interference with its person, or its freedom of action at meal-times. The damaged brain was subsequently examined, and it was found that by far the greater part of the so-called motor area had been destroyed. It will be remembered that a similar case was exhibited by Professor Goltz at the International Congress of 1881.

The return of the German Cholera Commission, already the subject of frequent telegraphic communications to the daily papers, appears likely to be a veritable triumphal march to the capital of the German empire. Preparations are being made in Vienna, as we announced some weeks ago, to receive Dr. Koch and his fellow workers with ceremony befitting the occasion, enlivened by the hospitality for which that festive city is rapidly becoming famous. The final reception in Berlin will take place under the auspices of a Committee, which includes among its members an array of names that will raise the event to the highest rank of importance amongst the numerous medical gatherings of the year.

The *Wiener Medicinische Wochenschrift* for March draws attention to the fact that not less than five petitions, most of them from Prussian doctors, are now before the Vienna Doctoren-Collegium, asking for "nostrifications," enabling them to teach and practise in Austria; and these are only examples of numerous similar requests preferred at Prague and Pesth, and that from men who have acquired a good name as scientific workers. Among those now applying at Vienna are Professor Eulenberg of Berlin, Professor Cöhn, the well-known Breslau oculist, and two Prague Privat-Docenten. The application of Professor Eulenberg excited a warm discussion in the Collegium. He expressed his desire to become a Docent, and to practise in Vienna, in which city also he could better prepare a new edition of his *Encyclopädie*. Professors Billroth and Stricker were of opinion that facilities should be given in compliance with the request; but Professor Brücke, observing that reciprocity in this respect is at present impossible in Germany, proposed and carried a resolution, that foreign practitioners should not receive "nostrifications" until the international conditions upon which these should be granted had been arranged, adding the wish of the Collegium that the same rule should be adopted by the other Austrian Universities. The statement that an agreement between the Austro-Hungarian and the German Governments had been recently agreed to permitting reciprocal practice by doctors on the frontiers, did not prevent the resolution being agreed to.

We wonder whether our readers have ever heard of the Monster Medical Book Club which has been organised by Johannes Alt, a Frankfort bookseller. In comparison with it, with its four hundred subscribers scattered over Germany, Austria, Hungary, Holland, and Belgium, and its circulating list of eighty-six periodicals in German, French and English, our small local book clubs sink into insignificance. Each journal may be kept a fortnight, and the subscription for the half-year amounts to a little over a twentieth of the value of the books chosen for reading. Thus, if the subscriber puts his name down for journals which together cost ten pounds a year, his half-yearly subscription will be thirteen shillings—the rate of subscription being somewhat reduced on his taking in a larger number, or a more expensive series of journals. Of the eighty-six journals on the list, as many as sixty-nine are in the German language; and of these, twenty-nine are classed under the head of General Medicine. Of English journals the list contains the *Lancet*, *British Medical Journal*, the *Medical Times*, *Brain*, and the *Sanitary Record*, and an equal number of American periodicals. On the whole, the prospectus of the club gives one quite new ideas of the literary activity of Germany, both as to writers and readers, and it is to be feared that the conditions in this country would not be favourable to an institution on a similar scale.

Dr. A. M. Hutchin, of Brooklyn, at the conclusion of an address on the "Reciprocal attitude of the Medical Profession and the Community," delivered before the New York State Medical Society, remarks that—"The community may suffer seriously by its patronage of nostrums and exclusiveness, but the community undergoes greater peril, and the *esprit de corps* of the medical profession is outraged infinitely more, by the incompetency to which it has given its diploma, and by the dishonesty and trickery in its ranks, which it sees but cannot control." Such wholesome and outspoken truth rarely reaches the profession. The Scylla and Charybdis endangering the work of consultants, are the fear of not acting in the best interests of the patient, and the dread of holding up a weak brother to something akin to distrust, if not scorn. The College of Physicians directs that when "any difference of opinion" arises, the "greatest moderation and forbearance" shall be observed, and yet we hear that "doctors differ," and Dr. Hutchins tells us pretty clearly the reason why.

Professor Goodell, of Philadelphia, publishes in the *Medical News* for February 16th a paper which he read at the Obstetrical Society of that city, entitled "A year's work in Ovariotomy." During 1883, he performed 25 completed ovariotomies which were attended by seven deaths; of these, four were performed in his private hospital, with one death, caused by the bursting of a pelvic abscess into the bladder. There were eleven cases operated upon in the hospital of the University of Pennsylvania, with only one death, and that from "hospitalism." The remaining ten were operated upon in their own homes, with five deaths. "I did not see again but one of these after the operation," Professor Goodell observes, "and she died in eight hours from shock. I am always sorry not to have the subsequent management of my ovariotomy patients, but this is not always possible. Our country women are very averse, not only to being operated upon, but also to being operated upon away from home. Hence their unwillingness to go to hospitals, and their proneness to delay matters

until they have become too weak to travel. Again, three of the seven fatal cases were at the time of the operation very ill from septic fever, caused by purulent cysts. In two, the cyst-walls had broken down from previous tappings, and this is another fault of our women, who insist on being tapped, and put off the operation until the cyst becomes very large or has contracted adhesions. Thus out of the 25 cases, there were only eight without adhesions. While my statistics do not make so good a show as those of British ovariotomists, there is this to be said in their favour—that I have never refused to operate on a woman however slim her chance of recovery."

A CHEERFUL practice, says an American journal, is undermining the cemeteries of San Francisco. The price of cadavers having advanced steadily for four years, the medical colleges found a scarcity of subjects. The professors, therefore, clubbed together, and hired a venal sexton to make a midnight raid upon the graveyards. Things ran smoothly until lately, when an able-bodied savant was buried. A burst of thunder startled the citizens the following night. There was a patter of buttons and coffin-nails upon roofs far and wide, and the sexton's wife awoke next morning to find herself a widow. It seems that the savant, a doctor himself, had directed a quantity of dynamite and fulminate of silver to be interred with him, and the unsuspecting caterer of the college was thus entrapped. The simple ingenuity and effectiveness of the invention seems to have tickled the San Franciscans, and the cemeteries are now being honeycombed with torpedoes and blasting powder, fuses, and percussion caps, to such an extent that the science of anatomy is practically brought to an end.

THE duty of Medical Officer of Health to the Port Sanitary Authority of the Second City in the United Kingdom, involves an amount of responsibility which may readily be imagined. In his summary for the past year, Dr. Stopford Taylor shows that 21,452 vessels were entered at Liverpool during 1883, and out of this number 46 were found either to have at the time of inspection, or to have had previously, cases of zymotic disease on board. The outbreak of cholera in Egypt seriously increased Dr. Taylor's work, since no less than three lines of steamers ply from Liverpool to India *viâ* the Suez Canal, the vessels for the most part carrying Lascar crews, it was only natural, therefore, that great anxiety should be felt, lest cholera should be introduced into this country by any of these vessels; singularly enough, during the whole of the year no case of infectious disease was either reported or found to have occurred on board any of them.

THE number of emigrants leaving the Port of Liverpool during 1883, was 45,671 fewer than in the previous year, the decrease being principally in those arriving for embarkation from foreign countries. The necessity for a strict medical examination of all emigrants arriving in this country to be trans-shipped, is instanced in Dr. Taylor's report, by the following circumstance: In the month of June, four emigrants from Scandinavia, a father and three sons, arrived at Liverpool, and went to the Alexandra Dock to embark on board a steam-ship on the point of sailing, the three boys were all found to be suffering from small-pox, and the whole party had to be removed to hospital. From observations recorded in this report it would appear that the condition of French, Spanish, Italian, Russian, and Greek vessels might be greatly improved; whilst that of German, Danish, Belgian, Dutch, Norwegian, and Swedish is satisfactory.

IT is claimed for the town of Hastings that this famous health-resort obtains even more than its fair share of sunshine. Mr. C. K. Shaw, the Medical Officer of Health for the Borough, in his annual report for the past year, states that when compared with all other British meteorological stations possessing sunshine recorders, Hastings was found to have been visited, during 1883, with the greatest amount of bright sunshine, more particularly during the winter months. This fact may, or may not, account for the lowness of the death-rate, which was but 15·85 per 1,000, or, deducting the deaths of visitors and non-residents (numbering 97), about 14·5 only. The deaths referred to the zymotic class of diseases were 35, or 55 less than last year, and 21·33 below the annual average. With the view of retaining, if possible, this sanitary reputation, Mr. Shaw suggests the erection of "destructors," to get rid of the dry refuse of the town, and the establishment of a public "abattoir," to do away with some of the evils of private slaughter-houses.

THE Government of New South Wales has sent Mr. Willows, its official veterinary surgeon, on a mission to Tasmania, to enquire into the alleged prevalence of tuberculosis among rabbits, at a station in the colony. He reports that he found that genuine tuberculosis was present in 37 out of 50 rabbits which were caught. This mission is connected with an enquiry, now being made in New South Wales, as to whether tuberculosis might not be propagated amongst the rabbits which infest the colony, and thus diminish their numbers, without danger to other animals or to human beings. The question is a very difficult one, and definite conclusions are not likely to be very soon arrived at. It is said that in some parts of New Zealand, in which rabbits have been excessively prevalent, large numbers are dying of tuberculosis. It is possible, by the spread of this disease, that some relief may, in time, be got from the rabbit-plague, but what may be the associated results it is impossible to foresee.

Now that domestic sanitation is becoming generally recognised as a something, the importance of which cannot be gainsayed, the appearance of a little tract, entitled "Hints on Sanitary Law," by Mr. G. F. Chambers, published under the auspices of the National Health Society, is especially appropriate. In a very small compass it gives the pith of, and references to, the Acts of Parliament relating to such subjects as the adulteration of food, bake-houses, baths and wash-houses, unwholesome food, common lodging-houses, nuisances, offensive trades and manufactures, over-

crowding, scavenging, sewers and drains, and such like. In an appendix is given a list of medical officers of health for the various districts in the metropolis. The National Health Society have done the public a good turn in issuing this little work.

Lord Carlingford will take the chair at the St. Mary's Hospital Festival Dinner, which will be held at Freemasons' Tavern on Wednesday next. The opening of the new wing by H.R.H. the Princess Louise, which was to have taken place on the preceding day, has been put off till the beginning of July, in consequence of the Duke of Albany's death.

The manifold reports of the manifold State Boards of Health in the United States are curious documents. One from Maryland is before us. The objects of the Maryland State Board are set forth under sixteen heads, and embrace pretty well everything—enumeration of the population, organisations of local boards, delivering lectures on hygiene, "stamping out" of small-pox, the convening of sanitary conventions, and divers other things, among which we must not omit the preparation, printing, and distribution of forty or fifty thousand circulars, on such subjects as, How to rescue persons supposed to be drowned—How to prevent the spread of scarlet fever, of diphtheria, of small-pox — How to disinfect—How to manage infants—How to manage children that are older ; and how to manage a great many other things. Whether the multifarious objects of the Board are carried very much farther than the preparing, loading, and discharging of its mitrailleuse of sanitary tracts, is not sufficiently clear from the pages of the bulky report. Dr. C. W. Chancellor prefaces the volume with a tedious discourse, full of undigested morsels, and swollen with flatus. Some statistical information has been obtained by sending by post circulars to various people. Whatever value it might have, if complete, is marred by the natural reluctance of busy men to fill up, without remuneration, many columns of facts and figures. A clerk of one the County Commissioners indeed, in answer to Dr. Chancellor, requires first ten dollars in advance, and the doctor expresses his wrath at the demand by italicising the sentence.

The greater part of the volume is composed of some nineteen papers read at the Baltimore Sanitary Convention, 1883, and is of some interest in a psychological point of view, for a perusal of these papers will convince any one that it is really possible for a considerable number of nineteenth-century English-speaking scientists to meet and talk for days together without discovering a new fact, or even a pleasant and agreeable way of stating old ones. Nevertheless, there is one thing in the report of great and abiding value, that is, mortality statistics of the city of Baltimore, in which the deaths from small-pox and also the deaths from all causes of the white and coloured races have been returned separately. Baltimore contains 59,620 coloured people and 348,900 whites ; the death-rate of the white in 1882 was 19·7 per 1,000, of the coloured 34 per 1,000 ; the number of deaths from small-pox of the white were 466, of the coloured 85 ; that is, the variola death-rate of the white was 1·3, of the coloured 1·4 per 1,000. The larger death-rate of the coloured may mean simply a high birth-rate, and it is a pity that only the birth-rate of the whole is given, but as that is just under 20 per 1,000 the explanation is improbable. Is that same mysterious and fatal influence that exterminated the Tasmanians, that is slowly but surely destroying the New Zealander, and that has followed the steps of the white man in all his migrations, still at work? The effects of contact between superior and inferior races, and the modification of disease by heredity, is a problem of the highest human interest. Our transatlantic cousins have the most ample facilities for collecting materials for the elucidation of these questions among the Indians and their descendants, and we hope their super-abundant energies will be applied to this rich and almost untouched field.

THE ASSOCIATION JOURNAL AND MEDICAL BULLETINS.

Last week's *British Medical Journal* contains as neat a piece of word-fence as one often meets with. It is hidden away in the smallest print in a little-read portion of the paper, but it involves a question as important to the dignity of the profession as many that are deemed worthy of more impressive type and phraseology. Last November, at the very time when the *Medical Times* was laying it down as a principle that it is unbecoming in a professional journal to publish the cases of sick or dead personages, Sir William Jenner, and seventeen of the most distinguished physicians and surgeons in this country, addressed a letter to the Council of the British Medical Association, calling attention to "the impropriety of violating the confidences of the sick-room, by publishing in the journal of the association the details of the illness of a patient." This memorial was considered by the Council in January last, and a reply was sent, accompanied by a memorandum on the subject by the Editor of the Journal, which is perhaps the cleverest thing that has ever proceeded from his adroit pen. "I have never published anything," he replies in effect, "but what has been furnished by the medical attendants in charge, who in numerous instances have been your own distinguished selves. The public and the profession are often very deeply interested in the progress of public persons of eminence during periods of anxious illness, which interest I have done my best to gratify ; but if you will get the Colleges to regulate the limits within which such information may be supplied by their Fellows to the medical journals for publication—for I still, in spite of what you say, adhere to my belief that some such information ought to be published—I will do my best to exercise a more rigid censorship." To that memorandum, it is not surprising to hear, no reply or acknowledgment has been received.

We can well understand why, in spite of the eminence of the memorialists, the Editor of the Journal was unable to keep a slight hint of scorn out of his reply

In a position of unexampled difficulty, he has achieved a most remarkable success, and he has a right to feel some confidence in his own judgment. The success is apparent to all, but the difficulties are not so easily estimated, least of all by the learned and honourable physicians, who have had no experience of commercial undertakings. The Editor of a periodical like the *British Medical Journal* has to retain the confidence and friendship of the chiefs of the association, to propitiate and, if need be, educate his publishing committee, to keep the body and tail of the profession interested without alienating its head, to satisfy swarms of discontented letter-writers, and, last but not least important, to keep together and extend his *clientèle* of advertisers. Firmly seated in the counties, he may be excused for thinking this dictation of London physicians a little unnecessary. If the readers down in Yorkshire or Dorset like to hear how much albumen Lord A's urine contained, and what was the weight of the Bishop of Grandchester's spleen, it is his business as a journalist to gratify them. Journals conducted on other lines have not been a success. Then these interesting details from the sick-room are sure to be quoted by the dailies, a point to which much importance has always been attached by medical editors. We have never ourselves been quite able to see why ; still, on such a point, the decision of a born journalist, like the Editor of the *British Medical Journal*, must be considered final. If, with his record of success, he still holds that it is necessary in the interests of his journal to publish some information, however limited, of the illnesses of great people, it must be conceded him—or else the whole constitution of the journal must be radically reformed, with results which one cannot foresee, but only forebode.

Our own opinion and policy on the question at issue are so well known, that it is hardly necessary to say that we most emphatically approve the protest of the memorialists. We even wish they had gone further and discountenanced the equally pernicious practice of publishing signed bulletins in the lay press. To our mind the violation of the sanctity of the sick-chamber—undesirable as it is—is not so great a matter for condemnation, as the veiled system of advertisement by means of signed bulletins. The worst feature of the publication of medical details of the illnesses of personages in the medical journals, is that they are sure to be transferred to the pages of the daily press, and we think that half the evil complained of would have been removed if the Council of the Association could have been induced to instruct the Editor of the Journal not to communicate such details to the lay papers. We trust that the matter will not be allowed to remain where it is, but that the President of the College of Physicians, who is currently reported to be deeply interested in the question at issue, will appeal for the united support of the profession. By instructing his scattered colleagues in the principle involved and enlisting their sympathy, he may possibly succeed in maintaining the honour and dignity of the profession, without impairing the success of the Association. On the other hand it is quite likely that he may find that the Editor of the *British Medical Journal* understands the rank and file of the profession better than himself. At any rate, the Council of the Association are quite justified in believing so, until the results of a poll of the profession on the subject have convinced them of the opposite. For our own part, we have the fullest confidence in the good sense and right feeling of the profession, and firmly believe that a journal conducted according to the strictest principles of propriety that could be laid down by the Censors of the College of Physicians, would be well supported, provided it were not too dull and unreadable. But that is only our individual opinion, the correctness of which has yet to be demonstrated.

SUPERINTENDENTS OF ASYLUMS AND THEIR WORK.

In another column we publish some observations, which we most heartily endorse, upon the management of lunatic asylums. Attention has on more than one occasion been drawn in these columns to the insignificant amount of scientific work that is done in our asylums, an amount which, taking into consideration the exceptional opportunities that exist in such institutions, constitutes a standing reproach to the profession. The author of the paper that we have in part reproduced lays his finger with the greatest precision upon blots that exist no less on this than on the other side of the Atlantic, and indicates with perfect accuracy some of their causes. But there is another cause that he has not touched upon, and the evil will not be remedied nor the reproach removed until this cause has ceased to operate. The matter to which we refer is of so delicate a nature that it has never been openly referred to, but the time has come for a little plain speaking, for we may be sure that if we do not ourselves amend our ways the power will be taken out of our hands. Reform is always more gentle and more acceptable when it comes from within than when it comes from without, and we, or those for whom we are speaking, the medical superintendents of asylums, may be quite sure that unless they mend their ways, and that right soon, a worse thing will ere long befall them. The coming Local Government Bill should serve to them as a pregnant warning. Committees composed of representatives of the ratepayers will closely scrutinize their past action, and, if it should be found wanting, they may depend upon it that they will be displaced in favour of others with a deeper sense of their responsibilities.

The charge that we are about to make does not apply to all superintendents. There are brilliant and most praiseworthy exceptions ; but it does apply to many. It is this : that they choose as their assistant medical officers not the best candidates ; not those with the best diplomas and testimonials ; not those best qualified for the work ; not those of the best standing in the profession, nor those of the greatest intelligence ; but those who are most likely to make agreeable colleagues, and least likely to provoke comparisons by doing original and independent work. It may be said that the appointment is made by the Committee and not by the medical superintendent ; but this is trifling with the question. In a few asylums the Committees do, it is

true, take the matter out of the hands of the superintendent, and appoint the best man they can find; but in the majority of cases the superintendent virtually makes the appointment. It is made upon his recommendation and nomination; and in the majority of cases the best man is not appointed. In many such cases the man appointed is chosen for his weak and pliable nature. When it is remembered that medical superintendents are chosen exclusively, and very properly so, from assistant medical officers, it will be seen that the course that we have described is calculated directly and very seriously to deteriorate the race of medical superintendents. It acts as an artificial selection and tends to secure the survival of the most unfit. Such a course is thoroughly and radically bad. It is unworthy of members of a great profession. It is unjust to the Committee who manage the asylum; it is unjust to the ratepayers who are taxed for its support; it is unjust to the medical profession; and it is most unjust to the patients who are the chief sufferers by it, who have no voice to complain, and whom the superintendent is especially bound to consider and to protect.

One practical point mentioned by Dr. Ayres is of great importance. It is obvious to every man who has ever worked in a hospital, that the medical superintendent and his assistant should visit the wards together. Not necessarily always, but certainly on frequent occasions they should visit the wards together; should together examine the patients, and determine the treatment. Is this the rule? No, it is the very rare exception. There are many asylums in which the superintendent and his assistant are never seen in the wards together; and there are some, with shame we say it, in which the treatment ordered by the one is habitually reversed at the next visit of the other. We do not ignore the difficulties under which medical superintendents are placed. They have first of all to satisfy their Committees; and the Committees, they say, do not care for scientific work. The Committees wish to see an asylum well administered, to see clean floors, neat dresses, well-kept lawns, efficient drainage, adequate water-supply, good laundry arrangements, stores equal to sample; and they are right. But it is not true that all Committees do not care for scientific work. Some, to our knowledge, deplore its absence in the asylums under their control; and where indifference exists, it should be combatted. The superintendent has an excellent opportunity in his annual report to create a sound and healthy public opinion in this matter, yet how many do so? We have before us the reports of many of our asylums for the year 1883, and in them we find abundant references to the waterclosets, to the cow-houses and piggeries, to concerts and fancy balls, but reference to the scientific treatment of insanity is in all, save a very few instances, conspicuous by its absence. We do not deny the importance of efficient administration and of occasional amusements. We do not say that superintendents should neglect these things; but we do maintain, most strenuously, that those who leave science out of the question, when it ought to be the mainspring of their life and work, are false to their trust as members of a learned profession.

THE VACANT CORONERSHIP.

The Lord Mayor of London and his Common Council will very shortly have to choose among the candidates for the office of coroner vacant by the death of Mr. Payne. His late deputy, Mr. Langham, also a member of the legal profession, has already been appointed by the Crown to the coronership of the Duchy of Lancaster, which was held together with that of the City by Mr. Payne, and this fact, together with his long experience of office, will doubtless conduce greatly to his chances of success in his candidature for the City Coronership As usual, with the want of combined action so characteristic of our profession, six or seven medical men have announced their intention of contesting the vacancy, but we trust that public spirit will prevail over self-interest, and induce them to retire in favour of the one, Dr. Wynn Westcott, who, in addition to high professional qualifications, has alone had practical experience in his capacity of deputy coroner for Central Middlesex.

The office of coroner is one of the most curious survivals of our ancient constitutional system, being, according to Blackstone, of equal antiquity with that of sheriff, but it has in the course of centuries undergone great changes, without having kept pace with the progress of medical science. By the statute of Westminster I., it was enacted that "none but lawful and discrete knights" should be chosen, and in the 25th of Edward III. a man was removed from the office, because he was only a merchant. By the same statute the coroner was prohibited from taking fee or reward under pain of a great forfeiture to the Crown, doubtless with a view to maintaining the purity of his judicial functions, but fees were allowed and regulated as early as 1488, by the statute of 3 Hen. VII., c. 1, of which Sir Edward Coke bitterly complained.

He is still elected by the freeholders of the county for which he is appointed, as were formerly the sheriff, justices of the peace, and other officers who are legally supposed to stand between the prerogative and the subject in the execution of the laws, and his duties consist in enquiring, when any person is slain or dies suddenly or in prison, concerning the manner of his death, as well as in cases of wreckage and treasure trove. At present, however, coroners are in practice exclusively concerned with the investigation of the causes of sudden or suspicious deaths, and though no special qualifications are laid down, and one or two coroners are men of no particular profession, public opinion has long determined in favour of restricting the appointment to lawyers or to medical men.

There is much to be said in support of the claims of each; and in any future Act regulating or reforming the office, it is to be hoped that some means may be found of securing the special knowledge and acumen of each profession. Should the office, as we fear is too probable, be finally made over to the lawyers, it will not be enough that the coroner shall be compelled to summon any medical man who may have seen the case before or soon after death, but he ought to have an assessor sitting by his side in the person of a medical man of known scientific skill. Such, indeed, is the law in Germany, a country from which we might well

borrow many useful lessons in legislature; there the ignorant jury, who are either a farce or a hindrance to justice, are dispensed with; there a lawyer and a physician, both servants of the State, and holding the respective offices of public prosecutor and medical officer of health, alike men possessed of special knowledge and experience, on hearing of a suspicious death or one coming legally under their cognisance, proceed together to the spot, hold a court, call what witnesses they think necessary, draw up a joint report and forward it to the judge of the district or other higher court, and on this report further legal action is taken if deemed advisable. This procedure has about it such a simplicity and reason, as with our patchwork legislation and adherence to ancient usage and effete institutions, we cannot hope to attain within half-a-dozen generations. We have, too, so many lawyers and so few doctors in Parliament that the former have it all their own way.

The duty of the coroner is to find out the cause of death, and since murders are happily of comparatively rare occurrence, the question is mostly whether the death was due to disease or not, and this is not fully solved unless the actual cause of death, *i.e.*, the precise nature of the disease, be distinctly ascertained. This, even a lawyer must admit, cannot be done but by a medical man. It is not enough to know that the deceased was suffering from a disease which might at any time prove fatal, for an invalid is as likely as a healthy man to be the victim of foul play, and perhaps more likely to put an end to his own miserable existence than one in the full enjoyment of life.

In support of the claims of the lawyers, it is urged that the coroner has to sift a mass of evidence, much of it furnished by ignorant witnesses, and to separate what bears on the case from what is irrelevant, that he must know what is legal evidence, and what is not. There is a certain amount of truth in this line of reasoning, but there is also a fallacy of omission. The evidence on which his decision, in nine cases out of ten, must ultimately turn, is evidence of a special and technical nature. Let us appeal, not to analogy, but to precisely parallel instances. No lawyer, or even judge, would presume to determine the causes which led to the bursting of a boiler, the fall of an iron bridge, or a building, the bursting of a piece of ordnance, or the capsizing of a ship, without the opinion of engineers, architects, naval men, or like experts, and yet these questions do not demand a life-long education and experience, any more than it does to arrive at a sound conclusion respecting the cause of failure of the vital machinery. Even if we ignore the fact that every clinical examination involves the process of sifting and weighing the very same evidence as is adduced at an inquest, which is really a *post-mortem* enquiry, conducted under the additional difficulty of the absence of the ante-mortem observation, the question whether a medical man can easier acquire a knowledge of the broad rules of evidence as accepted in courts of law, or a lawyer make himself master of pathology, with the sciences of physiology and anatomy on which it rests, without having studied in a medical school, is one which no one, not blinded by prejudice, could have a moment's difficulty in answering. This, however, is supposing that things must remain as they are. The German practice, or some similar arrangement, removes the dilemma. We have no hesitation in saying that half the inquests held at present are horrid farces, painful to the friends of the deceased, with no advantage to the cause of justice, and that while verdicts of "visitation of God," are simply profane, those of "natural causes," when no means have been taken to show what the causes were, or even that they were natural in any other sense, than that they were not *super*-natural, are, to say the least, a waste of public money, leaving the public as wise or as ignorant as they were before.

CLINICAL PAPERS.

X.—The Law of Substitution in Epidemic Disease, as Illustrated by Pneumonia.

The familiar illustration of several persons exposed in common to some morbid influence, whether chill or malaria or sewer gas, and each of them responding after his own manner, although often quoted is, perhaps, not considered and applied as it ought to be as a law of disease applicable to communities as well as individuals, and calculated to throw light upon many obscure phenomena.

Take, for example, the class of affections caused by exposure, and conveniently grouped together as "chill diseases." Speaking generally, the respiratory mucous membranes will suffer from chill causes in an order corresponding to the degree of exposure: coryza, bronchial catarrh, bronchitis, occur respectively in a decreasing order of frequency, just as the several seats of those affections recede farther and farther from the external air. But along with this—the general liability of mankind—many special liabilities have to be taken into account, both those which concern individuals and those which concern particular seasons; so that what is recognised as the common rule may be modified or superseded by individual predisposition, or some special "influence" of the time.

It is the same with other diseases, the pythogenic or the septic. There is the ordinary and expected mode of suffering in response to each of these; and there is the extraordinary and exceptional mode. Malaria, sewer gas, septicæmia, each has its recognised disease expression. But there are other expressions than these, less common and less easy of recognition. Enteric fever or diphtheria or the prevalence of diarrhœa is supposed to get its explanation so soon as some drainage defect is discovered; but it would require far more evidence to show that pneumonia or tonsillitis was of similar origin.

And what is true of individuals is true of communities. The people from time to time respond to morbid influences in some new and unaccustomed way, and not as the books teach. The east wind of spring ceases to give "cold," and gives headache, want of appetite, and aching of the bones instead. The filth

accumulation of a crowded court fails to provoke the familiar typhoid fever, it provokes pulmonary inflammation or ordinary sore throat. The contagion of some specific fever is no longer made outwardly manifest by a skin eruption, it appears under the form of an internal inflammation, an acute pneumonia, it may be, as infectious and sometimes as virulent as small-pox.

And observe that in all these instances the same law obtains as in the case of several persons all exposed together, where, according to the common parable, one shall get pneumonia, another nephritis, a third biliary catarrh and jaundice, a fourth an ordinary cold, and the rest nothing. There is no tendency, as we might have expected, to a mingling of these several effects of the one injurious exposure. There is no individual of the company who will combine the results. He that gets the nephritis is saved the pneumonia, and he who gets the jaundice escapes coryza. The common cause acts in several different ways. It does not act, as one might suppose, *à priori* (the great bane of practical medicine), in the same sort of way throughout, only tending more to the lungs in one, more to the kidneys in another. The morbid influence spends itself in one direction.

And this, too, is true of communities as well as of a single group of persons. When, for example, the form of illness which succeeds to foul dwelling or filth accumulation is not of the usual kind we begin very properly by doubting whether the assigned cause is the true one. But, supposing the question of cause settled, what we do next is to look for some trace or other of the more familiar effects of pythogenic poisoning to assure us of the genuineness of the less familiar. To be certainly associated with unhealthy dwellings, the tonsillitis must have some diphtheritic character; the pneumonia must be of "a low asthenic type," and not the strong and frank disease which commonly goes by the name, and is thought to have nothing "enteric" or "typhoid" about it.

But Nature is not thus conservative. While we are looking for modifications she has accomplished a revolution. The modes of response to morbid influences vary indeed so widely, that if we will but look a little beyond our own narrow life time, it is difficult to comprehend, or even name, the countless forms of epidemic sickness of which history tells. But be the forms what they may, their succession represents not change merely but a series of transformations. And so it is now. The response will be either this or that, the usual one or the less usual, it will not be—or, at least, as a rule, it will not be—any sort of combination of the two.

Let me give an illustration or two. A main sewer is opened opposite a boys' school, and sewer gas is suffered to escape into the sleeping rooms that overlook it. And while the observers, who have vainly protested against this proceeding, are awaiting the consequences and looking for enteric fever or some array of gastric or intestinal symptoms, there comes instead an epidemic of veritable lobar pneumonia. Or again, some houses of a city slum are reported by the sanitary inspector. But when proof is sought of actual harm, traceable to the drain defects that have been pointed out, there is no better evidence of that kind than the fact that several of the tenants have died of acute pneumonia. Need it be said that in neither of these instances would a solitary case of pneumonia have sufficed to call attention to the actual cause of it? We have, indeed, our own pattern of pythogenic pneumonia, one which is evolved out of our own consciousness, and closely connected with diarrhœa, gastric disturbance, enteric fever, and other known effects of bad sanitation. But acute lobar pneumonia is credited with quite different associations, and, inasmuch as the houses of the poor are very commonly draughty as well as pestilential, there is little difficulty in attributing such attacks to some weather cause rather than to the breathing of poisoned air.

A word may be added upon the practical side of this subject as to its effects, especially the vexed question of prognosis in pneumonia. It is well known that in a majority of instances (the proportion is very variously estimated, it is three-quarters according to Grisolle, and nine-tenths according to Ziemssen, but certainly it is a majority) the exciting cause of pneumonia is *not* exposure. It is admitted now that some of these numerous unclaimed cases are certainly of pythogenic origin. But the admission has been long delayed, owing to a gratuitous preconception which demanded that the lung inflammation should be exhibited *along with* enteric and gastric symptoms, and not in place of them. And from not discerning the source of the disease we miss its spirit and significance. The various admonitions of practice relating to "typhoid," and "latent," and "erysipelatous," and "apex" forms of pneumonia are very fallacious guides, so far as prognosis is concerned. Pneumonia must be judged by its origin. It is good or bad according to its source; and it is because its causes are so many, and so little regarded, that its death-rate is so variable, and the issue of each individual case so doubtful. Separate from the gross total of all the pneumonias that have happened—say in London, during the last ten years—all the aged, the starved and the drunken—a pretty constant ratio from year to year—and along with these you will subtract a large proportion of the fatal cases. Separate next all the cases of pythogenic origin—a ratio that is constantly varying—and, again, you draw away a large proportion of fatal pneumonia.[1] There will be still a remnant that is left, and as yet, perhaps, not separable; the pneumonia plausibly ascribed to various nervous accidents, and having a very variable, yet certainly a high, rate of mortality. But this also removed, what remains will represent the pneumonia of the books—the pneumonia which it is so pleasant to treat and to read about, and the contemplation of which has given birth to the belief that this remarkable disease — which, in fact, comprehends under a common name the most innocent and the most destructive forms of inflammation known to us—has always and inherently a natural tendency to recover.

Ψ

[1] It is well known that a certain number of cases of pneumonia, mistaken for typhoid fever, are admitted yearly into the fever hospitals of London. The discovery of such mistakes affords no doubt, legitimately enough, that self-contentment which is proper to those who see farther than their neighbours. But, if the rate of mortality of such cases were known and their source investigated, it would probably appear that the error was not so grievous after all.

REVIEWS AND NOTICES OF BOOKS.

MEMORIALS OF AN UNQUIET LIFE.[1]

If one rises from the perusal of Dr. Williams' Memoirs with the impression that the chief characteristic of his life has been its turbulence, the author has only himself to thank for it. He has treated in such detail the half-dozen controversies in which he was engaged, that one is apt to forget the many years of quiet and honourable work which lay between them, and to think of him only as a man who had always a grievance. This is unfortunate, and will do much to impair the popularity of a book which is otherwise most interesting and instructive. That Dr. Williams, in more than one instance, met with rather unfair treatment, in respect to both his scientific and practical work, no one who has studied his book will deny; but here, too, it will probably be admitted that the blame very largely rests with himself, and that he would have found more liberal consideration at the hands of his colleagues if his own attitude had been less aggressive. It would ill become medical workers of the present day to forget or ignore the important services which Dr. Williams has rendered to clinical medicine and pathology; but a constant parade of achievements is very apt to defeat its own ends, and we do not doubt that it has done so in the present case. We must take, however, qualities with their defects, and admitting that the scientific enthusiasm and devotion which enabled Dr. Williams to rise, in spite of so many disadvantages, to such a high place in contemporary science, may have been inseparable from an undue sensitiveness to praise and blame, give him our ungrudging gratitude for what he discovered and taught.

Dr. Williams tells us that he never went to school, but was kept at home at Heytesbury, in Wiltshire, taught by his father and allowed to give full scope to his predilection for natural science, until he was old enough to enter at the Edinburgh University. There are few clever men who would not be ruined by such a prelude to active life, and it is greatly to Dr. Williams' credit that the only harm he derived from it was a certain persistence of rough corners, which a few years of public school life would in all probability have effectually rubbed down. The same defect has been noticed in other clever home-bred men. It greatly interfered, for instance, with the influence which John Stuart Mill, of whom a pleasing description is given in the present volume, would otherwise have exerted upon the actions, as distinguished from the thought, of his day. In other respects the course of education which Dr. Williams' father laid down for his promising son was eminently judicious, and far in advance of what was thought necessary by other fathers of his day. He evidently had firm faith in his son's capacity, and determined that he should enjoy the best advantages in the way of education that the world then afforded. He sent him to study medicine for four years at Edinburgh, then, in 1820, far and away the best medical school in the United Kingdom, and subsequently allowed him to spend a winter in London, and eighteen months in Paris, the wisdom of which course was fully apparent in after years. The reputation of the French school of science and medicine was then at its *acmé*. La Place, Humboldt, Cuvier, Gay-Lussac, Arago, and Ampère were amongst the immortals who met at the Academy of Sciences, whilst at the hospitals Andral, Broussais, Louis, Laennec, Esquirol, Dupuytren, Larry, Roux, and Boyer were actively engaged in those observations and researches which made the school of Paris famous throughout the world. Dr. Williams, with a happy instinct, attached himself to Laennec, and he could not have arrived at a more fortunate moment, for it was the last year of the great clinical teacher's life, when he was most matured by the latest observations and practice. Dr. Williams came back to London a practiced auscultator, with a knowledge of chest disease superior to that of any London physician then practising. Fortune had so far favoured him and he showed himself not unworthy of her gifts. There was a long struggle before him, and what London physician, however distinguished, escapes it? But with his abilities, and his start in life, ultimate success was certain.

After publishing his work on "Auscultation," Dr. Williams married and settled down in Half-Moon Street in 1830. He was soon engaged in active literary work for the "Cyclopædia of Practical Medicine," and, before many years, became entangled in his first controversy, that with Dr. Hope. In 1835 he was elected a Fellow of the Royal Society; but his paper "On Low Combustion" not having been deemed sufficiently profound for a place in the *Philosophical Transactions*, he was indisposed to look favourably on that Society, and for many years preferred to bring his best work before the British Association. In 1836 he began his career as a lecturer, and delivered two courses at the Kinnerton Street School of Anatomy, which were subsequently published in the *Medical Gazette*. The reputation thus gained was, no doubt, a main factor in procuring his election over the heads of formidable competitors to the Professorship of Medicine at University College in 1839. So far his career had been one of uncertainty and struggle, his expenses exceeding his income by an average of 600*l*. a-year; but at length his position was assured, and his further success depended only on the maintenance of his own health and strength. In 1840 he was elected to the Fellowship of the Royal College of Physicians, and the next year was chosen to deliver the Gulstonian Lectures, which were subsequently published in the *Medical Gazette*. He had been recently investigating the phenomena connected with the circulation of the blood in the capillaries, and he devoted his lectures to a consideration of the results of these observations. In 1843 he published his *magnum opus*, the once well-known "Lectures on the Principles of Medicine," which passed through three editions, and was for many years regarded as the standard work on the subject.

The years of struggle over, and the place of the leading authority in his own special branch awarded him by general consent, one might have expected that the interest of Dr. Williams' life would have been over, and that his history would thenceforward be as uneventful as that of most successful physicians. But some

[1] "Memoirs of Life and Work." By Charles J. B. Williams, M.D., F.R.S. London: Smith, Elder, and Co., 1884.

evil genius seemed to preside over his existence and never to leave it long untroubled. We cannot even enumerate all the troublous episodes which followed quickly upon each other. Into more than one he was forced by the best of motives—the desire to reform what appeared to him to be abuses—but others he might have escaped if he had been willing for a time to possess his soul in patience. We will pass lightly over these matters, with a wish that Dr. Williams had done the same. It is pleasanter to turn to the honours showered upon him by an admiring profession. In 1846 he was elected first President of the newly-formed Pathological Society, and twelve years later he received a similar honour on the foundation of the New Sydenham Society. In 1862 he was chosen to give the Lumleian Lectures, and selected for his subject "Sketches of Success and Failure in Medicine." In these lectures he especially dwelt upon the prevention of disease as being the highest grade of success to be obtained by medical science—a truth which, years before, he had been the first in this country to grasp. In 1873, Dr. Williams was chosen President of the Royal Medical and Chirurgical Society, the next year was appointed Extraordinary Physician to the Queen, and it appeared likely that he would easily attain to the highest honours of his profession. But at this juncture his health broke down, and he refused in quick succession the Senior Censorship of the College of Physicians, the office of Harveian Orator, and the offers to deliver the address on medicine at the London meeting of the British Medical Association, and to be put in nomination as representative of the London University in Parliament. Possibly, too, but for doubt as to his ability to undertake the active duties of the office, his candidature for the Presidency of the College of Physicians would have been more actively pushed by his friends, and he might have been elected in preference to Sir James Alderson. There have been few physicians who, belonging originally to no London Hospital, and with little extraneous help, could quote a similar record of distinctions.

In the few lines yet left us, we would reiterate our opinion that the book under review is, in spite of its blemishes, a singularly instructive and interesting one. Of a liberal—and in some respects a radical—tendency Dr. Williams was in many points ahead of his generation, and his remarks on matters of medical interest, even though written years ago, will secure the fullest approval of the modern reader. The book, too, is full of entertaining personal reminiscences, and scattered up and down it are many practical hints of the greatest value. There are, indeed, few men who in the retirement of their old age have retained so fresh an interest in the subject of their life work, and have kept so well abreast of advancing science as the author of these memoirs.

Measles in St. Petersburg,—*The St. Petersburger Medicinische Wochenschrift*, for April 19th, states that a very destructive epidemic of measles has been prevailing in that city. The mortality is very large (52 deaths in a population of 923,016 during the week 18–24 March), especially in the children's hospitals. The Society for the Care of Poor Children has opened a temporary measles hospital, to the erection of which Her Majesty the Empress has contributed 1,500 roubles.

ABSTRACTS AND EXTRACTS.

NEUROLOGY.

OUR ASYLUMS AND OUR INSANE.

Under this title Dr. Samuel Ayres, of Pittsburg, contributes a paper to the *American Psychological Journal*, from which we select the following extracts:—"That there is in the minds of persons competent to form an opinion on the subject much dissatisfaction with the present management of our asylums, and a growing distrust in their efficiency as places of cure for the insane, cannot be doubted. Nor is it uncommon to find those who have passed some years in these institutions as medical officers, sharing this distrust and criticising some peculiarities of the system which have given rise to it. What is the cause of this general dissatisfaction and want of confidence? Is the system defective? I shall endeavour to answer these questions as they relate to the following subjects, and will propose under each paragraph what would seem to be the remedy needed.

"I. *Superintendents.*—It matters little, I believe, how splendidly built and equipped is the asylum, how attractive and beautiful the location, how complete and systematic its organization, how perfect its arrangements for heating and ventilation, how fine its furnishings, or how faithful its board of managers, if the superintendent be not a humane and scientific physician, whose heart is in his work, and who gives his entire time to the study and treatment of his patients. If he fail in these, the inmates will be neglected, the percentage of cures will be reduced, and abuses of various kinds will be frequent; while the chief end for which the asylum is erected, viz.: the cure of the curable, and the proper care of the incurable—will be, in a great measure, defeated. There is no disguising the fact that a superintendent cannot be at the same time purveyor, farmer, florist, horticulturist, paymaster, clerk, steward, financier, board of managers, lobbyist, etc., etc.—and practising physician. It is simply preposterous, and yet it is daily attempted, to the detriment of all concerned, As matters are now conducted in many of the asylums, it would certainly appear that the growth of cabbage and currants interests this official more than morbid growths within the encephalon; that the location of a turnip or potato patch interests him more than the localization of cerebral lesions; that the ripening of a new variety of strawberries interests him more than the origin and development of delusions; that it is rather his ambition to have the asylum an extensive and well-regulated insane boarding house, than a hospital for the study, treatment, and cure of mental diseases. It is urged, however, in reply, that he need not 'fritter away his time' in the details of all departments, but simply direct their chiefs, and exercise a general supervision, while the assistant physicians are attending to the medical interests of the patients. Theoretically, this seems reasonable, but practically it results only in harm. Whenever the physician-in-chief assumes the functions that belong to an executive board, or undertakes the direction of all the affairs about an asylum, he becomes involved in endless details, his mind is engrossed in a multitude of matters, his attention is diverted from the patients, and he loses, to a great extent, medical interest in them. This is about the result of such a course, argue as you will upon it. The *remedy* is simple. Let the superintendent be a physician of high medical attainments, skilled in the practice of medicine, and then specially qualified in nervous and mental diseases. Let him devote his whole time to the care and treatment of his patients, just as the general practitioner does to his. Let him have absolutely nothing to do with the ordinary business and administrative affairs of the institution, but let these be entrusted to the proper officers, who shall report to the executive board. The minor details of management and organization, which I have not time to indicate, would then follow in their proper order.

"II. *Assistant Physicians.*—When our medical colleges shall establish chairs of nervous and mental diseases, and didactic and clinical psychiatry is the rule and not the rare exception; or when the assistant physicians to our asylums

are selected only from those who have taken a special course in insanity, then we may hope that these officers will enter upon their duties reasonably prepared. Until such a desirable state of affairs is realised, it is but just to them, and particularly to the inmates, that they receive all possible assistance from superintendents upon diagnosis, clinical history, and treatment; and that they be not left unaided in the treatment of a disease most obscure to them. As a result of their inexperience, and this neglect by superintendents, they must, though studious and closely observant, pass two or three years in experimental treatment; and, if they be not students, striving to scientifically interpret symptoms, and to intelligently treat their patients, though they pass twenty years in the specialty, their entire course will be but one of guesswork and empiricism. The most intimate professional intercourse should at all times exist between a superintendent and his medical assistants, and, accompanied by them, he should visit one department daily, and thus see all the inmates every two days, instead of every three months, as we have heard of. He could then institute such measures and treatment as are indicated, and follow them up by constant observation. The assistants should keep a daily clinical record of each case receiving medical treatment, as is done in our best general hospitals, and also note the condition of interesting chronic or incurable patients, which record may be consulted on his daily visitations by the chief officer."

"IV. *Asylum Therapeutics.*—As many of the asylums are now conducted, it is not to be wondered at that the strictly medical therapeutics of insanity is much neglected. And that a routine, both in prescribing and dispensing, prevails, which would simply amaze the active and wide-awake general practitioner. In certain forms and stages of insanity the administration of proper medicines may be attended by effects as pronounced and beneficial as in any other disease. While it is equally certain that pathological processes let alone or ignorantly attacked, generally leave their victims beyond all help. It is the duty of asylum physicians to give this subject more attention and study.

"V. *Pathological Work.*—The amount of this done in our asylums is very limited, indeed, is attempted in only a few. When we think of the vast quantity of valuable material for this study to be found in these institutions, it is a matter of profound regret that so little of it is utilized. There is no reason why the work should not be undertaken, even in a small way, in all hospitals. But the failure to do so is a natural consequence of the imperfections in the system, and the inexperience of superintendents in pathological investigation."

EFFECTS OF POLITICAL EVENTS ON THE FORMS OF INSANITY.

This was the title of the introductory lecture of Dr. Legrand du Saulle (reported in No. 13 of *Progrès Médical*) at the Salpetrière this year, in which he pointed out that war and rioting only induce insanity in the predisposed. There was no increase in the number of the insane during the troubles that prevailed from 1847 to 1854, and it was the same during the events of 1870 and 1871. In his opinion, speculation, the thirst for gold, and sudden changes in fortune, are the chief causes that provoke insanity. The constantly increasing resources of the Assistance Médicale, by enabling it to aid so large a number of patients, have materially influenced the statistics of mental diseases—for formerly a large number of epileptics, imbeciles, and persons suffering from senile dementia, who would have remained unnoticed in the rural districts, are now inmates of asylums. If the events of 1870-71 have exerted any decided effect on the mental condition of the Parisian population, it is because they modified the conditions of existence. Thus, on the declaration of war, when a considerable number of young persons joined the colours, numerous cases of sub-acute alcoholism were met with among quite young people, as a consequence of the excesses committed under the influence of the emotion caused by the approaching departure. When the enemy approached, and investment was menaced, the population of the suburbs took refuge in Paris, and these unfortunate beings, in a state of constant anxiety and anguish, insufficiently aided and badly fed, furnished a good many cases of melancholic insanity. Other disturbances arose under the conditions of existence necessitated by the defence. The men passing their time at the fortifications and committing excesses in drink, were in large numbers attacked with sub-acute alcoholism, while the ill-fed women presented the psychical disturbances due to inanition—hallucinations, melancholic delirium, &c. Still, insanity, properly so-called, seemed to have decreased. At the time of the bombardment, the inhabitants of Montrouge took refuge in the other districts, and a great many became subjects of panophobia or "perplexed melancholia," several of the women presenting, without any period of invasion, the phenomena of melancholia with stupor or stupidity. During all this period, the epileptics in the Salpetrière underwent no increase in the number of their attacks. One single category of the insane exhibited a notable increase, viz., the *inventors*, who still continued numerous until the period of the Commune. In conformity with the documents on the hereditary and personal antecedents of the subjects of psychical disturbances during this period, the existence of obsidional insanity cannot be admitted.

The pathogenic influence of the events of the siege was not only felt among adults, but was also very marked on the development of infants conceived at this epoch. The numerous disturbances in their evolution observed among infants born in the later months of 1871, and the exceptional mortality which occurred amongst them, caused them to be designated by the working population as *les enfants du siège*—a name synonymous with an ill-formed infant destined to a fatal lot. Among 92 infants conceived during the siege, Dr. Legrand du Saulle found that in 64 there were physical, intellectual, or moral anomalies, the remaining 28 being in general small and sickly. As to the pathogenic influence under which these anomalies are developed, that must be a complex one, the principal elements of which are alcoholism, inanition, and the psychical condition determined by the moral shock under circumstances so eminently dramatic.

"What is Meant by Nervous Prostration?"—In this paper (*Boston Medical and Surgical Journal*, January 17th), Dr. Roberts Bartholow remarks, with reference to the now often heard terms "neurasthenia," "nervous prostration," "hypochondria," that the corresponding French word, used in the same sense as we now employ it, has been a stock word of French neurological medicine for fifty years. There are two types of this "neurasthenia"—the *congestive* and the *anæmic* varieties. After describing in detail cases which illustrate these two forms, and pointing out that in each the functional nervous disturbances were secondary to derangements of the assimilative processes, and that to the functional disorder thus caused are added the effects of introspection and the realisation, to an unusual extent, of ordinary peripheral excitations by the centres of conscious impression, the author continues: "The brain, of all the organs of the body, illustrates in the most perfect manner the 'principle of least action.' So far from being injured by severe labour carried on under normal conditions, the brain is improved by it. Mental activity keeps the brain in a healthy state. When, therefore, a man says he is suffering from the effects of mental overwork, I want to know what his vices are. Worry may be one of these. The worries of life do infinitely more harm than the work of life, howsoever hard that work may be." He denies that life is more exciting on his side of the Atlantic; "it is the very ease and luxury of our American life that cause mischief. It is the indulgence in eating and drinking, the abuse of alcohol and tobacco, sexual excesses, sedentary habits, and too luxurious lives generally, that induce the state of the system called nervous exhaustion." To the question, why are the somatic derangements caused by the conditions referred to, in some cases accompanied by the mental and nervous symptoms of neurasthenia, and not in others? he replies, that in the conduct of life every man who has a position to make or to obtain, exerts a certain moral force to hold himself up to his work. Some men are so happily constituted that they are quite unconscious of the effort and stand in the front, serenely confident. Others are all the time labouring, they feel it,

and they know it. Men conscious of the effort made to keep up, need but little excuse to surrender themselves to their sensations. At the present time nervous prostration is much feared, its symptomatology is a common subject of discussion, and hence, if a man who is familiar with its character is arrested in his career by some of the ailments supposed to belong to it, his imagination readily supplies the rest. No part of the body is without sensation even in health; to perceive these sensations, the attention needs only to be withdrawn from external things, and concentrated on the part. Thus, when the subject of neurasthenia pursues his introspection, he becomes conscious of numerous sensations which, because now felt for the first time, are new. Suggestion adds its quota of symptoms, and to these subjectively developed nervous symptoms must be added the reflex—headache, vertigo, tinnitus, palpitation, asthma, neuralgia, &c., &c. "Indeed there is no symptom in Beard's catalogue of those belonging to neurasthenia, that may not be due to merely reflex influences having their initial seat in the digestive apparatus. It follows that the term neurasthenia, or its common equivalent, nervous prostration, is either inadequate, or it expresses too much, —inadequate if the complex of symptoms includes the functional disturbances of all the organs affected; expresses too much if the malady is merely a nervous one." Dr. Bartholow would define "nervous prostration" as "a disease usually functional, situated in one or more organs, during the course of which reflex disturbances of the brain occur, and numerous subjective sensations in all parts of the body are realised by the consciousness;" he denies that it is a primary nervous affection, or a substantive disease, but regards it as symptomatic and secondary. This conception fixed in the mind, the treatment of neurasthenia is successful or unsuccessful according to the measure of our skill in localising the initial disturbance, and in addressing our remedies to that as well as to the general state of the patient.

Cysticercus of the Brain.—In the March number of the *Archives de Neurologie*, M. Bernard records a case of this somewhat rare affection. The patient was a man, aged 24 years, who had suffered from attacks of headache and vomiting for a year when he came under observation. These attacks were accompanied by vertigo and transient loss of vision. Latterly the headache had become constant; there was no loss of motor power, but the patient staggered in walking, and complained of numbness in the right side of his face and tongue. There had also rapidly ensued impairment of vision. On examination, there was marked retraction of the field of vision, especially on the right side; his colour fields could not be taken, the visual acuity was much diminished on the right side. The pupils were dilated, and very sluggish both to light and during accommodation; there was a typical "choked disc" on each side. After his admission to the Salpétrière the vomiting was checked, but he suffered much from headache and from vertigo, and he gradually became quite blind. He died from double pneumonia. At the necropsy, a small sac was found just in front of the optic commissure, but not having any direct relations to it; a second sac was seen depressing the second frontal convolution on the left side; and a third embedded in the wall of the fourth ventricle, on a level with the left eminentia teres. There was evidence of inflammation of the ependyma here, and a general increase of cerebro-spinal fluid. It is to this third cyst that the author would attribute all the symptoms observed. The cysticercus which was found in it, measured five millimetres in length, four in width, and three in depth.

Cortical Lesions of the Brain.—Following the example set by MM. Charcot and Pitres last year in the *Revue de Médicine*, Dr. Allen Starr has commenced in the April number of the *American Journal of Medical Sciences*, a paper on the above subject. In this, his first instalment, he deals with the non-motor area. Fifty cases collected from American medical literature are quoted with more or less detail; of these no less than 23, or nearly one-half, relate to lesions of the frontal lobes. The first case is that known as the crowbar case, the others include damage to the frontal lobes from bullets and other foreign bodies, from abscesses, and from tumours of various descriptions. Putting all the cases together he found that mental disturbance had been present in one-half; it took the form of loss of control and change of character. Memory did not appear to be affected, but the faculties of judgment and reason were strikingly impaired. In other respects the evidence furnished by this group of cases was negative, and the diagnosis of lesion of the frontal convolutions would have to be based upon the presence of mental disturbance, with general symptoms of cerebral disease, and the absence of motor or sensory disorder. The eleven cases of lesion restricted to the temporo-sphenoidal lobes which are here collected, do not lead to any very definite conclusions, except that the areas for motion, sensation, and vision do not lie within them. A more careful study of the special senses in cases of brain disease might, Dr. Starr thinks, show that some had their origin in this region. The cases of disease confined to the occipital lobes tend to support the contention already put forth by Dr. Starr that the visual area in the brain is situated in this region. The cases of disease only in the parietal lobes are naturally few in number, they seem to show that the motor area does not extend back behind the ascending parietal convolution, and they do not support Landouzy's hypothesis that the centre for the movements of the eyelids is in the pli courbe.

The Diagnosis of Hysterical Hemiplegia.—In a clinical lecture, which M. Marie has recorded in the *Progrès Medical* (No. 11), Prof. Charcot describes a characteristic case of hysterical hemiplegia. The patient was a young woman, aged nineteen, who had had some manifestations of hysteria at the age of sixteen, but had since remained well. On the day following a somewhat severe shock caused by a shelf falling on to her during sleep, she was suddenly seized with right hemiplegia, without any warning at all. When she presented herself at M. Charcot's clinique three days later, the leg had already improved somewhat, but the arm hung by her side, she could extend it a little, and could just move the fingers, there was no rigidity. She dragged the leg a very little in walking, the face was not paralysed The tendon reflexes were rather diminished on the side affected. There was loss of common sensation and loss of the muscular sense in the right arm. The temperature of this arm, too, was distinctly lower than that of the other. The absence of any paralysis of the face, and the co-existence of loss of sensation and of muscular sense enabled M. Charcot to exclude a cerebral lesion, and in the same way a spinal lesion could be dismissed, as had that been the case, the anæsthesia should have been on the side of the body opposite the motor paralysis. The application of the Faradic current for a few minutes sufficed to entirely dispel the motor and sensory paralysis.

Disseminated Sclerosis.—The study of a case of disseminated sclerosis which, in its clinical features, closely simulated lateral amyotrophic sclerosis, has given M. Déjérine (*Revue de Médecine*, March) the opportunity of making some interesting and valuable remarks on the pathology of scleroses in general. The case which forms the starting point of the paper was that of a woman, aged forty-six years, who had had for fourteen months atrophic paralysis, with contracture of all four limbs. The disease commenced in the legs, spreading thence to the arms, and ultimately to the lower part of the face, the paralysis of the limbs became absolute, and the atrophy extreme; it was throughout symmetrical. An interesting feature of the case was the high degree of contracture which was present, so great was it that it could not be altogether overcome by the employment of force, the tendon reflexes were

highly exaggerated. The general and special sensibility was unimpaired; but towards the end there were some symptoms of labio-glossal paralysis. At the autopsy it was found to be a case of disseminated and not of lateral amyotrophic sclerosis. Spinal and cerebral scleroses, M. Déjérine goes on to say, may be and ought to be divided into primary when the neuroglia is affected from the outset by the irritative process, and secondary when it is only the result of the nerve disorder. In disseminated sclerosis the affection of the neuroglia is primary, as is shown by the fact that the nerve tubes and axis cylinders disappear very slowly from gradual compression by the contracting neuroglia. In tabes dorsalis, the contrary is seen; for the axis-cylinder disappears before the neuroglia has commenced to proliferate. Disseminated sclerosis, then, and probably all forms of non-systematic sclerosis have a vascular origin; whereas, in systematic sclerosis, the vascular lesions which are present are secondary. Thus, in a case of hemiplegia, fatal just when rigidity was setting in, the vessels of the pyramidal fasciculus were already found to be undergoing endo- and peri-arteritis, and their lymph sheaths were distended with corpuscles; but the nerve tubes showed a much more advanced state of degeneration, the axis cylinders having already disappeared, and the neuroglia showing traces of irritation at a point far removed from the vessels, contrary to what takes place in non-systematic sclerosis. The vascular origin of the patches in the latter explains both their scattered distribution and the absence of any tendency to spread in a systematic manner.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 25TH, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

Epithelioma of the Tongue, involving the Floor of the Mouth, Left Tonsil, and Soft Palate.—Removal by the Buccal Operation.

MR. F. J. GANT, in communicating this case, said that the principal points of importance were—the unusual extent of the disease for which the operation was performed; and that the method by buccal incision offered the only, or the readiest, way of removing the tongue and adjoining parts involved, in order to extirpate the whole of the disease, under these exceptional circumstances. The question was also raised as to the desirability of reaching the tongue through the cheek in all cases. Having related the history of the case, the operation, as performed with the chain-ecraseur, was fully described. The above propositions were then considered.

Mr. JESSETT enquired whether Mr. Gant would always prefer the use of the ecraseur to that of scissors. He thought, that if sufficient time were allowed for the operation, the scissors would give the most satisfactory results, the surface of the wound being left in much better condition for immediate healing. The dangers and difficulties of hæmorrhage were rather apt to be exaggerated. He had not met with a case where the whole growth could not be thus simply removed, and he thought that the scissors could always be used effectively without dividing the cheek.

The PRESIDENT called attention to the relation of the molar tooth to the growth, and asked if any causative importance had been attached to it.

Mr. GANT, in reply, said, that from their exact correspondence in position, he had thought that there must be a direct relation between the tooth and the growth. The various methods of operating through the mouth were all open to objection in cases of large growth; the submental operations, although in some cases admitting of more complete control of hæmorrhage, did not permit of the same access to all parts of the mouth and pharynx as the buccal operation. He considered that Syme's operation of dividing the jaw was an unsurgical procedure, except in cases of very extensive disease, and in such cases removal had better not be attempted. The removal of large growths, by means of scissors, through the mouth, was in some cases impossible; and he thought that the difficulties and complications which would attend the conversion of an oral into a buccal operation were such as to render the proceeding hardly feasible. In every respect, therefore, he would give the preference to the buccal operation.

A Case of Gluteal Aneurysm.

A paper on this subject, of which the following is an abstract, was read by Mr. G. R. TURNER:—Samuel P., aged 51, coachman, was admitted into the Seamen's Hospital, Greenwich, on September 17th, 1883. He had been previously under the care of Mr. Roper, of Lewisham, from whom the following history was obtained:—On September 5th the patient was thrown out of a pony carriage, and when seen by Mr. Roper, was found to have a scalp wound, exposing bone on the right side of the head, and a contusion of the back, right hip, and buttock. He did well till September 14th, when, without leave, he got up. On getting back into bed he felt something snap in the right buttock. Immediate swelling came on, and when Mr. Roper saw him, this swelling had most distinct pulsation. Ice was applied locally, and in two days the pulsation ceased and the tumour became hard and painful. On his admission into the Seamen's Hospital, the integuments over the swelling were inflamed, and there were marks of fading bruising extending over the buttock up to the scapula. No pulsation or thrill in the tumour, which measured some eight inches by six. The man had been a hard drinker, probably had had syphilis, and both radial and temporal vessels were atheromatous. There was some slight fever on his admission. This subsided after a few day's rest, and the condition of the integuments became less inflamed. The tumour, however, became larger, and fluctuation marked. At one place the skin, on September 30th, was prominent and thinned, the superficial inflammation returned, and the temperature rose again. On October 9th, it was evident a portion of the skin had lost its vitality, and that the tumour was on the point of bursting. Exploratory puncture with a fine trochar showed that the superficial part of the swelling was solid, and gave rise to a flow of bright arterial blood from the deeper part with no relief to the tension. On October 10th the patient was put under ether, the sac of the aneurysm laid open from end to end, and more than 42 ozs. of disintegrating blood clot turned out. An oval aperture about the size of a split pea was found in the gluteal artery just as it left the pelvis. A carbolised silk ligature was placed on either side of this, and tied. The vessels were diseased. During the operation the rectal lever was used, and but very little blood, except that in the sac of the aneurysm, was lost. Previous examination by the rectum showed the swelling was extra-pelvic. The gluteus medius, minimus, and the external rotators of the thigh were exposed at the bottom of the sac. The gluteus maximus was completely destroyed. The wound was plugged with a carbolised sponge, and dressed with carbolic gauze. The man did well for eight days, when tetanus attacked him, and he died exhausted on the eleventh day. By that time the wound was granulating healthily; all the sloughs had separated, and all ligatures had come away. No injury to the gluteal nerve could be detected. At the operation the vessel was completely isolated, and seen perfectly before ligature. No *post-mortem* examination could be obtained. The diagnosis in this case

presented no difficulty, although, but for the history, the swelling at one time might have been mistaken for an abscess. It bore no resemblance to tumour of bone. At first it seemed possible that a natural cure would result, and it was not until the tumour was on the point of bursting that operation was undertaken. As the danger of secondary hæmorrhage is so very great, laying open the sac was delayed as long as possible. The rectal lever proved most efficient and should be superior to an abdominal tourniquet in such cases. Since Mr. Holmes's lectures in 1874 two cases of gluteal aneurysm have been recorded—one by Mr. Hussey, of Oxford, in Vol. XIII. "St. Bartholomew's Hospital Reports," in which death occurred from secondary hæmorrhage on the sixteenth day after laying open the sac; and another by Dr. Sands, of New York, in the *American Journal of Medical Sciences*, April, 1881. Examination by the rectum in this case showed the sac to extend into the pelvis, and the internal iliac artery to be diseased. Pressure was made by the hand in the rectum on the common iliac vessels on two occasions for 1½ and 3¼ hours, and caused on each occasion some clotting of blood in the sac. Eventually, however, the aneurysm resumed its former condition, and in spite of instrumental pressure, the patient was discharged in the same condition as on his admission.

Mr. Pick, having been present at the operation, praised the efficiency of the rectal lever and thought that its introduction had robbed the great operations about the hip of half their terrors. He was perfectly sure that the gluteal nerve in the present case had not been included in the ligature, a point which was of importance in seeking for the cause of the subsequent tetanus. He would have preferred, in dealing with the gluteal artery, to have divided it and tied the two ends.

Mr. T. Holmes expressed an opinion that these cases of gluteal aneurysm were of extreme rarity. He had never seen one himself. In collecting cases, however, for his lectures at the College of Surgeons, he had found that most of those recorded as aneurysms were in reality formed as a result of injury, as in the present case. When there is a wound in a main vessel producing a pulsating tumour, there is but little hope of spontaneous recovery, and in such a case as Mr. Turner's, operation was the only treatment. He disagreed with Mr. Pick as to the necessity for dividing the vessel before tying it, nor did he think that the chances of secondary hæmorrhage would be in any way influenced by it. Complete division of an artery in bleeding from a small wound in its wall, was a well-known procedure in surgery, and, in the days of temporal arteriotomy, was constantly practised. A very important point in dealing with these cases was to ascertain the exact position of the wound in the artery by means of rectal exploration. Several fingers, or even the whole hand, might be introduced into the rectum and the condition of the vessels determined. If the tumour were found to be intrapelvic, he thought that it would be a rash proceeding to attempt to lay it open, and one which would probably necessitate ligature of one of the great arteries. He regarded Davy's rectal lever as a most valuable surgical invention, and by far the best means which we at present possess of controlling hæmorrhage in such cases. The abdominal tourniquet and pressure by the hand, or by pads and straps, were all open to special objections from the local injury which they might themselves inflict. He was convinced that no damage had been done to the gluteal nerve during the operation, but thought that the amount of irritation set up around it by the aneurysm must not be disregarded. It was probable that many of these so-called gluteal aneurysms were often due to injury of vessels other than the gluteal, but in any case the rules for treatment remained the same. He looked upon Mr. Turner's paper as a valuable contribution to surgical literature, and thought that the case, except for the accident of the tetanus, must be regarded as successful in its result.

Mr. H. Morris thought that it was unnecessary to specify the gluteal nerve as the starting point of the tetanus, the amount of local injury, and the pressure exercised by the swelling upon surrounding tissues, would afford sufficient explanation for its occurrence. Referring to the delay in operating upon the present case, he expressed an opinion that it would have been better to have operated at once, and he considered that, as as rule, these cases, where a radical operation is called for, are far too often postponed until good results become impossible.

Mr. G. R. Turner, in reply, observed that he would have willingly adopted Mr. Pick's suggestion to divide the artery had it been made at the time of the operation. With respect to immediate operative treatment, he pointed out that it was only applicable to cases of wounded vessels, and not, as in this instance, to cases of rupture, in which the diagnosis is of necessity less certain. The occasional improvement in his case had led him to hope that it might result in spontaneous cure.

Extensive Thrombosis following Fracture of both Bones of the Forearm.

The following case was communicated by Mr. Arbuthnot Lane:—On the 9th November of last year the patient fell heavily on her left side down some steps, breaking both bones of the forearm, the ulna at its centre, and the radius at the junction of the middle with the lower third. There was much displacement of the radial fragments. The shoulder and arm were also much bruised. The swelling subsided within a few days, and the arm progressed very favourably till the 29th November, when sub-inflammatory œdema of forearm set in and extended into the upper arm. It was accompanied with much pain and tenderness, especially along the front of the forearm and course of the brachial vessels. It almost completely subsided only to reappear more extensively on December 21st accompanied by still greater pain. It again subsided, and again returned on January 5th. This time it extended up to the shoulder. She had now great pain in the neck and above and below the clavicle. By January the 15th, the left side of the chest, neck, and face were much swollen and were extremely painful. There was also severe headache in the left side of the head. She was very prostrate. Dr. Carrington, who saw the case with him at this time, also felt no doubt that the thrombosis had extended along the subclavian to the innominate and internal jugular veins, and a rapidly fatal termination was feared. However, the swelling slowly subsided from the left side of the face, then from the neck, and then from the side and upper arm, and by February the 6th it was limited to the forearm and lower third of the upper arm. On February the 9th she had a recurrence of the swelling which extended to the side and neck, with pain and tenderness. This subsided, so that she was able to get about and commence to use her hand and arm which was progressing very favourably. The radius has, however, not united by bone. On April 1st, without any apparent cause, a rapid and complete recurrence of the swelling took place, not, however, being accompanied by the same very great pain, nor with such severe headache. The left side of the face was much swollen, as were her neck and side. This swelling of the face and neck subsided, leaving by April 10th the left side and back of the chest about two inches larger than the right, and the left arm a good deal swollen, so much so that she could not use it. There was a firm resistance along the left internal jugular. She continues to improve steadily.

Mr. T. Holmes asked for further particulars as to the progress of the fractured radius which had not healed with the ulna. He referred to a paper by the late Mr. Callender on the non-union of fractures in consequence of thrombosis of the great veins leading from the seat of injury. He thought that the delayed union in the present case might be explained by the frequently recurring obstruction of the veins.

Mr. LANE replied that the fracture had remained for six months ununited, and there seemed no probability that union would take place now.

Dislocation of the Elbow backwards, with Fracture of the Coronoid Process.

A paper, with this title, by Dr. H. A. LEDIARD of Carlisle, of which the following is an abstract, was read by Mr. R. J. Godlee:—A young fisherman, aged 28, fell whilst wrestling, his hands touching the ground in the prone position with the arms extended. He heard a distinct snap. After undergoing a course of unsuccessful manipulation by a bone-setter, he was admitted into the Cumberland Infirmary with displacement of both bones of the forearm backwards, causing almost complete inability to produce either flexion, pronation, or supination. Concomitant fracture of the coronoid process being diagnosed, excision of the joint was performed. The patient was well in a month, the movements of the new joint progressing satisfactorily. The specimen (which was exhibited) showed that a considerable piece had been broken off the coronoid process, the fractured surface having eroded and polished the posterior surface of the trochlea. The head of the radius lay behind the capitellum, the sigmoid cavity in its centre being filled up with a semi-fibrous mass, which would have formed an insuperable obstacle to the reduction of the dislocation. A small chip of bone was found adherent to the capitellar surface of the humerus, possibly a part of the fractured process. The opinions of most authors agree in regarding this injury as extremely rare; in two cases however, in which dislocation of the radius and ulna recurred after reduction, Dr. Lediard had been able to diagnose fracture of the coronoid process, in addition to the displacement.

Mr. GODLEE remarked on the very small size of the fragment of bone which was assumed to be the fractured coronoid process, but which he himself would take to be a splinter of bone accidentally chipped off at the time of the accident.

Mr. T. HOLMES thought that the question of fracture of the coronoid process was viewed in a somewhat different light now than was formerly the case. He gave details of two cases of undoubted fracture with dislocation. In the present case, he had no doubt as to the genuineness of the fracture; but he believed that the detached fragment still remained in the arm, not having been removed at the time of the excision.

Mr. GANT thought that the injury was a very rare one. The fragment of the coronoid process would of necessity be drawn up by its attached muscles, and the dislocation would be sure to remain unreduced.

Mr. H. MORRIS pointed out that if the fragment were drawn up by the action of the brachialis anticus, the fracture must be low down, and a swelling would thus be produced which could hardly fail to be detected. He thought that the rarity of these cases might be attributed to the extreme difficulty attending the diagnosis of many injuries about the elbow joint.

The following Living Specimens were shown:—

Congenital Hypertrophy of one Limb; by Mr. R. W. PARKER.

Case of Voluntary Starvation in a young Girl; by Dr. HERON.

ROYAL FREE HOSPITAL.—The Lord Mayor presided on Wednesday, April 23rd, at Willis's Rooms, at the annual festival dinner held in connection with the above hospital. Speaking of finance, he said the hospital was entirely dependent for support on subscriptions and voluntary donations and legacies. The annual expenses amounted to 10,000*l.*, while no more than 2,000*l.* was received from subscriptions and other sources. During the evening subscriptions were announced to the amount of 1,635*l.*

HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 17TH, 1884.

Dr. PERCY BOULTON, Vice-President, in the Chair.

Diarrhœa in Children.

DR. LEES, in his paper, called attention to a class of cases, not very uncommon in children, in which the main symptom is an irresistible impulse to defæcation, experienced almost immediately after food has been taken. Colic pain may, or may not, be present, but there is no sensation of weight at epigastrium, heartburn, flatulence, or other symptom of dyspepsia. The motions are usually semi-solid, not often watery or slimy, and frequently contain undigested food. Usually a motion is passed almost immediately after every meal, and perhaps once or twice more during the twenty-four hours. Dr. Lees pointed out that these symptoms are evidently due to a hyper-peristalsis of the alimentary canal, without increase of secretion, the two factors of ordinary diarrhœa being here disassociated. Such increase of peristalsis is probably due to irritation of the vagus nerve, which supplies the excitor fibres to the intestine, the splanchnics conveying the inhibitory fibres. The proximity of the nucleus of the vagus to that of the trigeminus, in the medulla, indicated the possibility that this increased excitability of the intestine may in part be due to dental irritation, the cases in question usually occurring during the period of the second dentition. Believing in the purely neurotic origin of the symptoms, Dr. Lees had treated several cases with bromide of potassium, simply without opium or any astringent, and had obtained immediate success, even in cases which had persisted for several months. The diarrhœa was usually arrested in a few days, and occasionally the children became so costive that the medicine had to be discontinued. Four cases were narrated, also a similar case occurring in an adult, in all of which speedy relief was given by bromide. In conclusion it was remarked that individuals who suffered from these symptoms were often of a markedly neurotic temperament, timid, and easily frightened.

Dr. DAY enumerated the various forms of diarrhœa met with in children, most of which could be shown to depend upon some error in diet. Cases such as those described appeared to own a nervous origin, and were amenable to appropriate treatment.

Mr. MIVART had met with several instances of the condition described. In one case, occurring in a telegraph-boy, he had employed bromide of potassum, with complete success.

Dr. ALDERSON recognised a neurotic form of diarrhœa in young children, and bearing in mind the efficacy of bromide of potassium in arresting the convulsions of dentition, he thought this agent might be found most useful in controlling the diarrhœa due to the same cause. Dr. Alderson mentioned that he had seen cases where mischief had been caused by prescribing prepared chalk and gum; such a mixture, although stopping the diarrhœa, subsequently produced hard fæcal concretions, and not infrequently led to peritonitis. He would like to have heard Dr. Lees' opinion as to the treatment of the dyspeptic diarrhœa of children as well as of those forms caused by filth, atmospheric changes, and defective sanitary arrangements.

Dr. EWART referred to the beneficial effects of arsenic in cases of diarrhœa set up by the ingestion of food, and to the success which attends the administration of small doses of grey powder in combination with aromatic powder of chalk in the diarrhœa which often accompanies the first dentition.

Mr. CRIPPS LAWRENCE, speaking of the diarrhœa of children during the second dentition, called attention to the mental restlessness peculiar to that age, which, no less than the tender gums, contributed in rendering mastication imperfect. Could not the satisfactory results obtained by Dr. Lees be in a great measure explained by the soothing effect of the bromide, and by the less hurried meals?

In his reply, Dr. LEES alluded to the mode of action of mercury in infantile diarrhœa; it probably was of service chiefly as an anti-putrefactive agent. Arsenic had been

stated by Dr. Clifford Allbutt to be contra-indicated in neurotic subjects. The kind of diarrhœa described claimed to be looked upon as a special variety, inasmuch as it was essentially independent of diet.

Acne Rosacea.

A paper was read on this subject by Dr. T. Robinson. Like lupus erythematosus, rodent ulcer, sycosis, and other lupoid processes, acne rosacea was almost universally limited to the face. In rare cases the disease appeared on the scalp of bald subjects, and it had been observed by the author to occur over the sternum. Acne rosacea was always associated with an irritable state of the mucous membrane, especially of the stomach. It was always heralded by futigive flushings of the face, especially occurring after food, but increased also by other causes, such as wind, exposure to sun, or soap. These flushings led to permanent dilatation of capillaries, followed by stasis, formation of papules, and all the inflammatory states peculiar to the malady. The inflammatory action might or might not involve the sebaceous follicles. The malady had a close relationship with what was known as relapsing erysipelas of the face, and with the vesicular and the non-vesicular erythema which attacked the same situations and obeyed the same laws. Lupus erythematosus was also akin to acne rosacea; It was not possible by any outward manifestations to distinguish one disease from the other in their early stages. Acne rosacea did not occur before the age of puberty; it was about equally distributed in the two sexes until the climacteric period of life, when it was seen much more frequently in the female, and was due in these cases to physiological activity of the hair follicles in the chin and upper lip especially, as is seen in the growth of hair in these situations at the said epoch of life. There were skins which could not develop acne rosacea; the latter was commonly only an expression of a local tendency in a general dartrous diathesis.

Dr. Alderson related a case of severe acne rosacea (in a young lady, aged sixteen), which had for a long time baffled treatment. When first seen by Dr. Alderson the appearance was almost that of semi-confluent small-pox in its pustular stage. A mixture, containing Decoct. Aloes comp. with Soda and Liq. Pot. Arsen. was prescribed; also a drachm of compound liquorice powder every night. The face was painted with a solution of nitrate of silver in nitric æther (3j. to ℥j.), and a poultice subsequently applied. Severe pain was set up, and after the application of a soothing lotion containing Zinc Oxide, Bismuth, and Liq. Plumbi, several of the pustules were lanced, and abundant pus let out. The caustic solution was applied repeatedly at intervals, and in the course of a month the patient was almost well. Dr. Alderson was at that time attending her father for a severe attack of acute eczema, associated with gout and with syphilitic psoriasis of the hands and fingers.

Mr. Drew gave an instance of the value of scarification in a case of hypertrophy of the nose associated with acne rosacea.

Dr. Lees referred to the frequency with which acne rosacea was found in those who were strictly temperate.

In reply, Dr. Robinson expressed an opinion that the case related by Dr. Alderson was one of acne indurata, rather than of acne rosacea. Scarification could hardly be of use in cases of true elephantiasis, but where acne rosacea was superadded to pre-existing acne of youth, this measure, as well as division of the enlarged vessels, might be tried with advantage.

Middlesex Hospital.—The secretary has issued an appeal for 15,000*l.*, for the purpose of carrying out a well-considered and extensive scheme for providing: (1) accommodation for the medical staff, (2) rooms for the servants, (3) an additional ward for male cancer patients, (4) a sick-room where any member of the staff can be isolated if attacked by severe or infectious illness, and (5) a re-arrangement of the out-patient department, long urged by the surgeons and physicians who have found it almost impossible to carry on their work under the present inconvenient arrangement.

GENERAL CORRESPONDENCE.

EXAMINATION FEES FOR UNIVERSITY UNDERGRADUATES UNDER THE MEDICAL BILL.

[To the Editor of the Medical Times.]

Sir,—I do not pretend to know "what was in the mind of the draughtsman of the Bill," nor is it material, inasmuch as he has certainly extended to simple matriculants of non-academic "Universities" all the privileges which were intended for undergraduates who reside and study in their University, and who pursue their Arts curriculum concurrently with their medical work. Moreover, the representatives of the Royal Irish University have availed themselves of the wording of the clause, and insist that their matriculant should receive his final examination at a nominal cost, although he has neither resided, studied, been supervised, nor pursued an Art's course in their institution, but has simply come up to the examining centre twice in the four medical years.

To obtain this exemption from final payment, the student simply pays 10*s.* for a matriculation examination, somewhat inferior in standard to the ordinary preliminary of a college, and 1*l.* nine months afterwards for a second examination in identically the same subjects. He works in any school he pleases, side by side with the student who is going for a collegiate license, but maintains no connection whatever with his University; and it is not until the end of the third year that he enters the walls of his *alma mater*, to be tested in medicine, for which he pays 1*l.*

His collegiate fellow-student, on the other hand, has to pass an examination at the end of each year, for which he pays 5*l.* annually, so that he has paid double in brain-work, and five times in money, for his examinations, and his Arts education is fully on a level with that of his fellow, the "University undergraduate." Yet, when these students come to the final examination, the University matriculant is to be treated as a superior and privileged individual, and is admitted at a nominal fee; though he has studied in the same school-museum and library as the collegiate student, is infinitely inferior in his examination tests, and has paid for them barely one-fifth of the money paid by his fellow.

Whether the University of London, or any other University, except the Royal Irish, answers to this description, I do not pretend to say; but I do assert that the Bill places every institution, which pleases to call itself a "University," on a perfect level, and gives its *alumni* a position of superiority and privilege to which neither their education nor the expenditure on it in any way entitle them.

I urge that such privileges should be limited, at least, to Arts graduates of three years' standing.

I am, Sir, yours &c.,

A. H. JACOB, M.D., F.R.C.S.I.

UNDER THE RED CROSS.

[To the Editor of the Medical Times.]

Sir,—You have so often permitted me to express my views on military medical matters in your influential columns, that I venture to ask you to insert this letter, expressing disagreement with one suggestion in an otherwise admirable article which appeared in your issue of April 19th, on the "Grievances of Army Medical Officers." You say, "Let the title of non-combatant be abolished." In my opinion the title should be retained, as expressing a great truth, and denoting a most dignified position. It is quite possible to understand that the word non-combatant may seem at first sight inapplicable to Army Medical Officers. They share all the risks and dangers of the battle-field with their combatant brethren, and they run far greater risks in times of pestilence. But if they were called upon to suffer twice as much, how would their position be improved by the abolition of the term non-combatant? Doctors they are and must remain. They have no other reason to plead for their existence in an army, than that they belong to a department, whose sole duty it is to repair the injuries

inflicted in battle, and prevent, if possible, the ravages of epidemics. It is the state of life in which it has pleased God to call them, and with many it is the state of life they have chosen for themselves. I grant that there is a kind of sting in the word non-combatant, which may irritate *young* medical officers, although it should not do so. The annoyance is heightened by, and perhaps arises from, the fact that the military medico is called upon by "Regulations" to be combatant "all over." From the cocked hat on his head to the spurs upon his heels he is a man of war, and has nothing to do with peace. Alas for the young doctor if his sword and stripes and gold lace throw him off his balance and make him despise his own profession! He cannot shake it off while he continues in the service; he cannot but remain the doctor. If the title "non-combatant" were dropped, nothing would be gained in social position unless some other titles were usurped. Supposing even that a medical man were permitted to use the relative rank as positive, and call himself colonel, major, or captain upon his visiting cards, what could he gain by it? In small towns and in county society these titles have still a little social value, although people hardly know why, but let no one suppose that a doctor would ever be allowed to dissociate himself from his professional status. The wiser members of the Army Medical Department have long striven for other advantages than could be obtained by masquerading as combatants. They have fought hard for power, but only for power over their own hospitals and all who do duty in them. They have expressed a wish for more consolidation as a scientific corps, a corps which can afford to dispense with long sword and sabretache. And there is no doubt that the Army Medical Department will get all these good things. Such a department need not shrink from wearing the Red Cross, nor fear to be called "non-combatant." When its members carry the badge they will but proclaim that they are anxious to do their proper duty. It is a curious illustration of inconsistency to find that at the Easter manœuvres numbers of men *in the ranks* bore the Geneva badge on their arms! It seems to me these fighting men in thus proclaiming themselves non-combatant were altogether wrong. The only men who should wear the cross "in the field" are the doctors of the Army Hospital Corps. It is the sign that the wearer is devoted to the healing art, and is strictly non-combatant. If men in the ranks wear the emblem of peace and good will no enemy will respect it, and the Geneva flag may as well be hoisted upon the General's head quarters as on the hospital tent. I would restrict the use of the Red Cross on a campaign to the members of the Medical Department, including, of course, all those under their command, and retain the honourable title of non-combatant.

I am, Sir, yours, &c.,

SENEX.

MEDICAL NEWS.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

A Meeting of Members was held on Wednesday, April 30th, at the temporary offices, 3, New Inn, W.C., when the following resolutions were passed:—"1. That we form ourselves into a body, to be called 'The Association of Members of the Royal College of Surgeons,' for the express purpose of obtaining certain rights and privileges in reference to the management of the College of Surgeons, which we do not at present possess. 2. That the above resolution be communicated to members residing in the chief towns of England and Wales, who shall be requested to act as Local Secretaries, and to enrol the names of members residing in their respective towns; and, further, that the Local Secretaries be asked to forward suggestions to be considered at the next Meeting of the Committee, on Wednesday, 14th May. 3. That a report of this meeting be sent to the Medical Newspapers." A proposal of Dr. Hickman (who was unavoidably absent) was mentioned by Mr. Forrest, to the effect that it was desirable that a joint association should be formed of Members of the Royal College of Surgeons and Licentiates of the Royal College of Physicians. Dr. Dowse observed that the former stood in an entirely different position to the latter, inasmuch as they formed a portion of the body corporate; whereas the Licentiates of the Royal Colleges of Physicians merely possessed a licence to practise, and were not members of the college. Dr. Warwick C. Steele thought that vigorous measures should be taken to suppress unprofessional conduct, such as advertising; he had sent advertisements he had received to the College of Physicians, the College of Surgeons, and the Society of Apothecaries, but one and all said they could do nothing. Dr. Foster MacGeagh said, that in conversation with him, Fellows themselves had admitted that their exclusive position was a matter of luck, and they could give no reason why members should have no privileges. Mr. M. G. Biggs, was of opinion that the Association should be based upon broad principles, and that their course of action should not be at first too closely defined, pending suggestions to be received from the general body of members. The following were appointed on the committee:—M. G. Biggs, M.R.C.S., 93, Northcote Road, Wandsworth Common, S.W.; Robert Collum, M.D., M.R.C.P., M.R.C.S., Sutherland House, Surbiton; T. Stretch Dowse, M.D., F.R.C.P., M.R.C.S., 14, Welbeck Street, Cavendish Square; Alexander S. Faulkner, I.M.D., M.R.C.S., 34, Southwick Street, Hyde Park, W.; William Hickman, M.B., M.R.C.P., F.R.C.S., 1, Dorset Square, N.W.; J. Brindley James, M.R.C.S., 47, Jamaica Road, Bermondsey, S.E.; Foster MacGeagh, M.D., M.R.C.S., Junior Athenæum Club, S.W.; F. St. George Mivart, M.R.C.S., L.R.C.P. Edin., 6, Devonport Street, Hyde Park, W.; James Newham, M.R.C.S., 16, Prince's Street, Cavendish Square, W.; Edward Semple, M.R.C.S., 24, St. Ann's Villas, Royal Crescent, Notting Hill, W.; Warwick C. Steele, M.R.C.P., M.R.C.S., Heathfield House, Ealing. At the suggestion of Dr. Collum it was determined to call the attention of members to the fact that the whole management of the College is in the hands of the 1,166 Fellows, the 16,258 members being absolutely precluded from expressing their views, except through the medium of the public press. Mr. James Rocheid Forrest, M.R.C.S., was elected Honorary Secretary to the Association.

Royal College of Physicians of London.—The following gentlemen were admitted Members, on April 24th, 1884:—

Coutts, John Alfred, M.B. Cambridge, Ladbroke Grove Road, W.
Murray, Hubert Montague, M.B. London, Canonbury, N.
Pringle, John James, M.B. Edinburgh, 35, Bruton Street, W.
Robinson, Luke, M.D. California, 48, Tavistock Square, W.C.
Squire, John Edward, M.D. London, 6, Orchard Street, W.
White, Ernest William, M.B. London, Kent Lunatic Asylum.

The following gentleman were admitted Licentiates, on April 24th, 1884:—

Alsop, Clement, 5, Upper Chadwell Street, E.C.
Andrews, Alexander Gordon, 44A, Coleshill Street, S.W.
Bean, Charles Edward, Guy's Hospital, S.E.
Biggs, Charles Edward Forbes, 17, Beaudesert Road, W.
Brodie, Charles Gordon, 12, South Crescent, W.C.
Butler, Gilbert Edward, Westminster Hospital, S.W.
Carnelley, Matthew, Guy's Hospital, S.E.
Carroll, Edward Richard William Charles, Cancer Hospital, S.W.
Claremont, Louis Bennett, Millbrook House, Harrington Sq., N.W.
Clark, Arthur William, Guy's Hospital, S.E.
Clarke, James Macfarlane, Infirmary, Manchester.
Coe, Henry Clark, M.D. Harvard, Detroit, United States.
Colman, Henry, Cumberland House, Kew.
Cook, Augustus Henry, 25, Dunning Road, N.W.
Davies, Sievwright Arthur, Llanelly.
Dodd, Arthur Herbert, 2, Petherton Road, N.
Ellison, William Augustine, Windsor.
Griggs, William Alfred, 11, Tressillian Crescent, S.E.
Hayes, James, Leigh, Lancashire.
Hoar, Charles Desambler, 4, Campden Hill Gardens, W.
Jones, David Llewellyn, Charing Cross Hospital, W.C.
Kendall, George, 126, Clapham Road, S.E.
Lilly, Alfred Thomas Irvine, 2, Milner Street, S.W.
London, John Edward, Berbice, British Guiana.
Lyon, Thomas Glover, 85, Asylum Road, S.E.
McDouall, Herbert Crichton, 11, Philip Road, S.E.
Maude, Arthur, 5, Bishopswood Road, N.
Milligan, Robert Arthur, 174, Coldharbour Lane, S.E.
Milnes, John George, 67c, Upper Tulse Hill, S.W.
Murray, Robert William, Guy's Hospital, S.E.
Mutis, Aureli, M.D. Columbia, 90, Charlotte Street, W.

Plant, Charles, Sandbach.
Pring, Arthur, Barnes, S.W.
Rands, St. John Outlaw, 22, Merrick Square, S.E.
Rushworth, Frank, Walton-on-Thames.
Sawers, Frederick Hayes, M.B. Toronto, Ontario, Canada.
Stace, Arthur Frank, Middlesex Hospital, W.
Street, Charles Tidbury, Bethlem Hospital, S.E.
Sturges, Frank, Beckenham.
Tireman, Arthur Lumley, Guy's Hospital, S.E.
Topham, Albert Stocks, Guy's Hospital, S.E.
Torres, Julio Zenon, M.D. Columbia, 90, Charlotte Street, W.
Tyrrell, Walter Guy Beauchamp, Great Malvern.
Wilson, Edward, 2, Cromartie Road, N.
Wright, Holland Hodgson, 3, Park Road Villas, S.E.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 24th inst., viz. :—Messrs. A. E. Garrod, Harley Street; G. A. E. Murray, Cape of Good Hope; H. W. Chambers, Lowestoft; F. C. W. Jones, Earlsdale, Pontisford; John L. Wright, L.R.C.P. Ed., Cape of Good Hope; John Reeks, L.S.A., Andover, and Thomas Jones, L.S.A., Hackney Road, students of St. Bartholomew's Hospital; H. B. Woolbert, Willesden; J. E. Blomfield, Launton; E. B. Parfitt, Notting Hill; R. H. Peck, M.A. Oxon, Penge Lane, S.E., and A. J. Turner, Hampstead, of University College Hospital; Hugh Lamb, Preston; W. H. Bowes, Herne Bay, and E. L. Brockliss, B.A. Oxon, L.R.C.P. Ed., Banbury, of Guy's Hospital; R. E. Molesworth, Kenwith, North Devon, and J. T. Williams, Warwick Street, S.W., of St. George's Hospital; A. W. Comber, Menbury Chard, of King's College Hospital; P. S. Hutchinson, Cavendish Square, of the London Hospital; and John Jenkins, L.S.A., Bristol, of the Bristol School. Six gentlemen passed in Surgery, and when qualified in Medicine will be admitted members of the College; three candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months, and one for three months. The following gentlemen passed on the 25th inst., viz. :—Messrs. W. C. Fenwick, L.R.C.P. Ed., Llangollen; J. G. Milnes, L.R.C.P. Lond., Upper Tulse Hill; G. H. De'Ath, Buckingham, and T. B. Jacobson, Sleaford, of Guy's Hospital; George Kirkhouse, L.S.A., Pontardarve, and Maitland Thompson, Workington, Cumberland, of St. Bartholomew's Hospital; H. C. McDouall, L.R.C.P. Lond., Blackheath, and Obadiah Johnson, L.S.A., Sierra Leone, of King's College Hospital; W. D. Anderson, Ballachulish, N.B., and H. A. Kent, Salisbury, of St. George's Hospital; W. G. B. Tyrrell, L.R.C.P. Lond., Great Malvern, and C. J. Wilkinson, L.S.A., Coatham, Yorkshire, of St. Thomas's Hospital; Frederick Morton, Bristol, of the Bristol School of Medicine; Charles Slater, Notting Hill, of the Cambridge School; and Charles Plant, L.R.C.P. Lond., Sandbach, Cheshire, of the Manchester School. Four gentlemen passed in Surgery, and when qualified in Medicine will be admitted members of the College. Four candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for three months, five for six months, and one for nine months. The following gentlemen passed on the 26th ultimo :—Messrs. G. A. Syme, M.B. Melb., Melbourne, of the University of Melbourne; H. G. Sworn, L.K.Q.C.P. Ire., Holloway, and F. H. Lane, L.S.A. Shepherd's Bush, of University College Hospital; J. W. White, L.K.Q.C.P. Ire., Camdem Road, N., of the Glasgow School; P. A. D. Head, L.S.A., Staines, and Ebenezer Bryceson, L.S.A., Shooter's Hill, of the London Hospital; William Urwick, L.S.A., St. George's Road, S.W., of the Westminster Hospital; R. T. Finch, Rochampton, and J. R. Collyer, Enfield, of St. George's Hospital; F. R. Humphreys, L.S.A., Finsbury, of Guy's Hospital; G. H. Monks, M.D. Harvard, Boston, U.S., of the Harvard University; J. T. Cheves, L.S.A., Devonport, of Kings College Hospital; B. G. Pullin, L.S.A., Sidmouth, Devon, of St. Bartholomew's Hospital.—Five gentlemen passed in surgery, and when qualified in medicine will be admitted members of the College, one candidate was referred for three months, and four for six months. The following gentlemen passed on the 28th ultimo :—Messrs. C. E. F. M. Biggs, L.R.C.P. Lond., Hammersmith; W. T. Strugnell, L.S.A., Portsdown Road, and W. R. de Morrini, L.R.C.P. Lond., Myddelton Square, of St. Bartholomew's Hospital; C. H. Pirsse, L.S.A., New Bond Street, and F. W. Kindle, King's Lynn, of Kings College Hospital; R. W. Murray, L.R.C.P. Lond., Blackheath, and S. H. Agar, L.S.A., Henley-in-Arden, of Guy's Hospital; D. P. Gaussen, M.D. Dub., Belfast, of the Belfast School; F. S. Turner, Chiswick, of University College Hospital, and A. Perry, L.S.A., Philpot Street, E., of the London Hospital. Eight gentlemen were approved in Surgery, and when qualified in medicine will be admitted members of the College. Three candidates were referred for three months, and five for six months. The following gentlemen passed on the 29th ultimo, viz. :—Messrs. W. H. Bailey, L.S.A., Colney Heath; S. M. P. Roberts, B.A., Cantab, Sheffield, and H. Parker, Highgate, of St. Bartholomew's Hospital; P. Jackson, L.S.A., Torrington, Devon, and P. R. Mander, L.S.A., Grimsbury, of the Westminster Hospital; A. J. Dixon, L.S.A., Donnington, and E. E. Newnham, L.S.A., Somersham, of the London Hospital; E. H. Freeland, L.S.A., Chichester, of the Middlesex Hospital; H. H. Lankester, L.S.A., West Kensington, of St. Thomas' Hospital; and H. C. E. Cooper, Finsbury Square, of Guy's Hospital. Five gentlemen were approved in surgery, and when qualified in medicine will be admitted members of the College; six candidates were referred for six months, and two for three months. The following gentlemen passed on the 30th inst.:—Messrs. C. Alsop, L.S.A., Teignmouth, A. C. Frames, L.S.A., Sidcup, and J. H. Menzies, L.S.A., Gwendwr Road, of St. Bartholomew's Hospital; H. H. Graham, M.B. Toronto, Toronto, of the University of Toronto; M. W. Roe, L.S.A., Melbury Osmond, and A. E. Hayward, L.S.A., Maxilla Gardens, W. of St. George's Hospital; A. C. Deare, L.R.C.P. Lond., Shepherd's Bush, of Guy's Hospital; W. A. Wetwan, L.S.A., Bridlington Quay, and F. Hichens, L.S.A., Redruth, of the London Hospital; P. E. Maitland, L.R.C.P. Lond., Albert Street, N.W., of University College Hospital. Four candidates passed the examination in surgery, and when qualified in medicine and midwifery will be admitted members of the College. Three candidates having failed to acquit themselves to the satisfaction of the Court, were referred to their further professional studies for three months, and seven for six months.

UNIVERSITY OF ST. ANDREW'S.—The annual graduate ceremony took place on the 25th ultimo, when Professor Bell Pettigrew, Dean of the Faculty of Medicine, presented the following for the degree of M.D.:—

Kenneth Mackenzie Chisholm, L.R.C.P. Ed., L.R.C.S. Ed., Radcliffe, Manchester; James Clapperton, L.R.C.P. Ed., L.R.C.S. Ed., Broughton, Winchester; Joseph Farrar, L.R.C.P. Ed., L.R.C.S. Ed., Morecambe; Thomas Frederic Higgs, L.R.C.P. Ed., M.R.C.S. Eng., L.S.A. Lond., Dudley; Edwin Hollings, L.R.C.P. Ed., L.F.P.S. Glas., London; Samuel Lloyd, M.R.C.S. Eng., L.S.A. Lond., London; James Lindsay Howison Herbert Porteous, M.R.C.P. Ed., F.R.C.S. Ed., Pathhead, Fife; William Smith, L.R.C.P. Ed., L.S.A. Lond., F.R.C.S. Ed., Eccles, Manchester; Edward Denham Tomlinson, M.R.C.S. Eng., L.S.A. Lond., L.R.C.P. Lond., A.M. Department; and Adam Wilkinson, M.R.C.S. Eng., L.S.A. Lond., L.R.C.P. Ed., M.D. Brussels, Shaftesbury.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 24th, 1884 :—

Allen, Charles, 36, Bedford Square, W.C.
Barber, Halford Vaughan, 108, Sandmere Road, S.W.
Carrington, Geo. Hedwig, Albert Street, Eccles, Manchester.
Fisher, Thos. Hammond, Manchester Road, Southport, Lancashire.
Grenfell, Henry Osborne, Calstock, Cornwall.
Reily, Alex. Yates, 34, Great Western Road, W.
Roberts, Jno. Saunders Hughes, Picton Place, Swansea.
Soutter, James, 3, Tremayne Terrace, Anlaby Road, Hull.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—At the April sittings of the examiners, the following gentlemen passed the primary professional examination of the Faculty:—Edward Ball, Wm. G. Booth, Charles S. Bowker, Morris G. Davies, Charles Dolman, John Eatock, Walter C. Halpin, Arthur Lindley, Archibald M'Arthur, Arthur R. Owst, Joseph S. Sergeant, Arnold E. Thorpe, Wm. F. C. Woodhead, Horan K. Young. The following passed the final examination for the licence of the Faculty :—John C. Aldred, Dore, Sheffield; Frederick H. Davis, Dawley; Wm. Duncan, Larne; James Herron, M.D., London; Edward Hopkins, Glasgow; Thomas M'Ilroy, M.D., Newtonards; James Miller, London; Wm. S. Pratt, Weedon; Geo. C. Richardson,

Glasgow; Thomas Russell, Glasgow; Robert W. Sclater, Kirkwall. The following passed the final examination for the double qualification granted conjointly by the Faculty, and by the Royal College of Physicians, Edinburgh:—Haggarth M. Addison, London; Wm. A. Algie, Glasgow; George B. Buttery, Govan; David P. Gage, Kilwinning; Henry A. Keegel, Ceylon; James M'Ilwrath, Glasgow; Ruys D. Morgan, Glasgow; Alexander A. Sutton, Glasgow; Edward Thomas, Glasgow; George D. Trevor-Roper, Maidenhead.

Royal College of Physicians.—At the last meeting of the Royal College of Physicians, the Fellows resolved that, instead of giving a *Conversazione* this year, the College shall have a Banquet, on a day to be fixed by the President. A committee was nominated to make the necessary arrangements.

The Hospitals' Association. — The second general meeting of the Hospitals' Association was held on Wednesday, April 23rd, at the rooms of the Medical Society of London, No. 11, Chandos Street, Cavendish Square. The subject under discussion was, "How far should our Hospitals be Training Schools for Nurses?" Papers were contributed by Dr. Bristowe, F.R.S., and Miss Eva Lückes, Matron of the London Hospital. For particulars as to membership, &c., application should be made to the secretary, at the office of the Association, No. 1, Adam Street, Adelphi, W.C. Ladies, as well as gentlemen, are eligible for election. Visitors are admitted to the meetings on the personal introduction of members or associates.

The Study and Cure of Inebriety. — Dr. Norman Kerr, the president of this newly-formed society, entertained a large number of guests, chiefly members of the medical profession, at an inaugural luncheon on Friday, the 25th ult. In the augural address which followed, Dr. Kerr laid stress upon the fact that inebriety is often a disease. The object of the society, he said, was to investigate, by strictly scientific methods, the various causes of inebriety, and to educate the professional and public mind to a knowledge of those causes, and to the recognition of the physical aspect of habitual intemperance.

The Health of Calcutta.—The *Times* Correspondont telegraphs that the effect of the rainfall on the health of Calcutta has been most marked. The cholera and small-pox epidemics which were raging with great violence in the native town, although still severe, have decidedly abated. It is to be hoped, he continues, that the exceptionally heavy mortality of the last six weeks will rouse the Calcutta Corporation to the absolute necessity of taking more active steps to provide a water supply for the entire city, to sweep away the filthy groups of huts, and to fill up the stagnant tanks, which constitute a permanent source of danger and disgrace to the Indian metropolis. The fact that the European quarters have been entirely free from epidemic disease gives one more proof, if any were needed, of the important part played by foul water in propagating cholera.

Naval Medical Department.—The following appointments are announced:—Deputy-Inspector-General George Mason, M.D., to the Chatham Division Royal Marines, *vice* Deputy-Inspector-General Jackson; Deputy-Inspector-General Francis W. Davis, to Bermuda Hospital, *vice* Deputy-Inspector-General Mason; Deputy-Inspector-General Gordon-Jackson, to Haslar Hospital, *vice* Deputy-Inspector-General Davis; Belgrave Nimmo, M.D., to the Chatham Division Royal Marines, temporarily; Valentine Duke, staff-surgeon, to the *Duncan*, additional, for temporary service, *vice* Davis; and Thomas C. Hickey, M.D., staff-surgeon, to the *Swiftsure*, additional, for Esquimalt sick quarters, *vice* Hervey.

South London School of Pharmacy, 325, Kennington Road.—The following prizes were presented to the successful competitors on Saturday, April 19th, 1884:—Senior Chemistry: F. Armstrong, Medal; F. W. Ashton, Certificate. Junior Chemistry: Thos. B. Blyton, Medal; F. W. Taylor and W. Holme, Certificates (equal). Botany: F. W. Taylor, Medal; G. D. Cooper, Certificate. Materia Medica: R. M. Stewart, Medal; T. J. Clarke, Certificate. Practical Pharmacy and Dispensing: F. A. Moss, Medal; R. M. Stewart, Certificate. Extra Certificates to Messrs. Atherton, Buxton, French, Hall, and Worfolk.

Vaccination in Scotland.—The Registrar-General for Scotland notes in his annual report the steadily increasing number of instances of infant vaccination being postponed on medical authority. No explanation, however, is suggested of this "noticeable feature" in the returns, although in 1882—the last year tabulated—the cases were as many as 495 above the average of the previous ten years. It is satisfactory to observe that the deaths from small-pox in 1882 were only four, being the lowest recorded since the outbreak of 1872, when 2,446 lives were sacrificed in Scotland to this terrible disease. The return for 1882, however, is only an estimate, as is that for 1883, when there appears to have been a slight increase, twelve deaths in the latter year being attributed to this cause.

Charitable Bequests.—The late Mr. David Brown, of Glasgow, has bequeathed to the Royal Infirmary, the Western Infirmary, and the Sick Children's Hospital, Glasgow, 500*l.* each; to the Eye Infirmary, the Maternity Hospital, the Lenzie Convalescent Home, the Dunoon Seaside Home, the Kirkintilloch Home for Incurables, and the Colquhoun Bequest for Incurables, 100*l.* each.

Diseased Meat.—A case, showing the importance of an efficient inspection of meat markets is recorded from Leicester. Four children and their parents were seized with violent illness as the result of eating calf's liver, and one of the children, aged 9, died. It was found on investigation, that the liver came from an animal which had been slaughtered for disease.

Munificent Gift to a London Hospital.—Mr. William King, of Ovington Gardens, South Kensington, a gentleman well known in art circles, has bequeathed the sum of 100,000*l.* to St. George's Hospital, Hyde Park, in the affairs of which he has taken a considerable interest for some time.

Social Science Association.—The Standing Committee on Health met on Tuesday, Sir Richard Temple, Bart., in the Chair, when the provisions of the "Dwelling Houses Inspection Bill" were considered. A resolution was unanimously passed regretting that as its clauses were of such an impracticable and unjust character, the Committee were unable to give the measure their support.

Coronership of the Duchy of Lancaster. — Mr. Langham has been appointed to this office in the place of the late Mr. W. J. Payne, whose deputy he had formerly been. The Duchy comprises the districts of Edmonton, Enfield, and Southgate, in Middlesex; the Liberty of the Savoy, in Westminster; and the parish of Clapham, in Surrey.

Death from the Bite of a Panther.—A young man has died at Shottenden, probably from tetanus, the sequel of a wound of the elbow, received in a struggle with a panther in China some month previously.

Royal Institution.—Professor Gamgee, M.D, will begin a course of five lectures on "The Physiology of Nerve and Muscle," on Tuesday next (May 6th).

Samaritan Free Hospital.—The Earl of Dalhousie has consented to preside at the biennial dinner on behalf of this charity, to be held at Willis's Rooms, on Tuesday, May 20th.

London Temperance Hospital.—The foundation stone of the new wing of this hospital was laid on the 24th ult. by the Duke of Westminster.

Opium-Smoking in the United States.—In his report on the drug trade for 1883, Mr. Robbins, of New York, calls attention to the fact that, while the importation of crude opium for medicinal purposes has varied but little (229,012 lbs. in 1883, compared with 227,126 lbs. in 1882) the increase in the importation of opium manufactured for smoking purposes, has been enormous. There were imported in 1883 298,153 lbs. of this vicious preparatiod, against 106,221 lbs. in 1882; and the Government received from it a customs revenue of nearly $200,000,000.

CHARITABLE FÊTE.—A floral fête and bazaar will be held in the Knightsbridge Riding School, early in July, in aid of the funds of the Surgical Appliance Society, for the relief of the crippled poor.

CRIMINAL STATISTICS.—An attempt is being made by some of the American Prison Societies to establish at Washington a permanent central office for the collation of the criminal statistics of the United States.

CONSUMPTION OF BEER IN ITALY.—This is ever on the increase, a fact which has its importance in a medical and hygienic point of view, inasmuch as this "invasion of northern drinks" must influence the public health. The use of beer is favoured, especially in the great cities, still more than by mere fashion, by the fact that the "national drink" undergoes by manipulation so many changes that it scarcely retains anything more of wine than the name. The increased consumption of beer may be judged of by its importation, for while this during the five years 1870-76 amounted to 26,681 hectolitres, it rose during the next three years to 49,609, and in 1880 to 43,110 hectolitres. The import of bottled beer has also doubled in amount since 1870-76.—*Annali Universali di Medicina, March.*

NAVAL MEDICAL SERVICE.—The following surgeons' appointments were made at the Admiralty on Saturday:—A. D. Peyton, to the *Firebrand*, when commissioned; H. Meikle, to the *Impregnable*, for temporary service; S. F. Hamilton, to the *Dolphin*, when commissioned; and D. B. Bookey to the Plymouth Division of the Royal Marines.

THE Library of the Royal College of Surgeons will be closed to-day (Friday, May 3rd) for the purposes of the Examinations.

APPOINTMENTS.

BARRS, A. G., M.D., M.R.C.P.—Assistant Physician to the Leeds General Infirmary.

CLARKE, W. B., M.A., M.B., F.R.C.S.—Surgeon to the West London Hospital, *vice* Alfred Cooper, F.R.C.S., resigned.

CHALMERS, GEORGE, B.M. & M.C. Edin.—To the Newbottle District.

HAWKINS, F. H., M.B.—Resident Physician to the Royal Infirmary of Edinburgh.

JACKSON, HENRY, M.R.C.S. Eng., L.S.A. Lon.—Medical Officer of Health for the Borough of Barnstaple, *vice* A. Fernie, M.D., deceased.

JACOB, E. H., M.A., M.D.—Assistant Physician to the Leeds General Infirmary.

MUDGE, THOS., M.R.C.S. Eng., L.R.C.P. Lond.—To the Western District.

SUTTON, H. M., M.R.C.S., L.R.C.P., L.S.A.—Junior Resident Medical Officer to the Great Northern Central Hospital.

WEISS, H. F., F.R.C.S.—Assistant Surgeon to the West London Hospital, *vice* William Bruce Clarke, M.A., M.B., F.R.C.S.

VACANCIES.

BRAINTREE UNION.—Medical Officer for the Finchingfield District, in succession to Mr. E. Dawson, resigned. Area, 8,387 acres. Population, 1,807. Salary, £80 per annum.

GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN, VINCENT SQUARE, WESTMINSTER, S.W.—Physician. Candidates must be graduates in Medicine, and Members of the College of Physicians of London. Applications, with testimonials, to be sent to the Honorary Secretary not later than May 7th.

HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE.—Resident Medical Officer. (*For particulars see Advertisement.*)

HOSPITAL FOR SICK CHILDREN, 49, GREAT ORMOND STREET, W.C.—Assistant Physician. (*For particulars see Advertisement.*)

SALOP INFIRMARY, SHREWSBURY.—House Surgeon. Salary £100 per annum, with board and residence. Candidates must be Fellows or Members of the Royal College of Surgeons of England, Edinburgh, or Dublin, and hold a qualification to practise medicine. Testimonials, with certificates of qualifications, to be addressed to the Board of Directors, not later than May 13th.

WEST NORFOLK AND LYNN HOSPITAL.—House Surgeon and Secretary. Salary £100 per annum, with board, lodging, &c. Applications, with testimonials, to be sent to the Secretary, on or before May 9th.

DEATHS.

DAVIDSON, THOMAS, M.R.C.S., B.A., at 44, Leamington Road Villas, W., on April 27th, aged 53.

BARCLAY, A. W., M.D., at Whitney Wood, Stevenage, Herts, on April 28th, aged 66.

TAYLOR, THEOPHILUS, M.R.C.S., L.S.A., at 94, Ebury Street, Eaton Square, S.W., on April 23rd, aged 60.

WOOD, JOHN, Brigade-Surgeon, at Beacon Hill, Lichfield, on April 27th, aged 58.

NOTES, QUERIES, AND REPLIES.

THE WHEATLEY MEMORIAL FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

DEAR SIR,—Will you kindly insert in your columns the second list of subscriptions to the Wheatley Memorial Fund? May I also be permitted to draw the attention of the Fellows of the Medical and Chirurgical Society to the existence of this fund, lest the circular issued in March by the Wheatley Memorial Committee have failed to reach a certain number of those who would wish to contribute.

Mr. John Cooper Forster, 29, Upper Grosvenor Street, is the Treasurer; and cheques may be sent to him, or direct to the Wheatley Memorial Fund, Union Bank of London, Argyll Place, Regent Street, London, W.

I am, dear Sir, yours, &c.,
BERKELEY HILL, Hon. Sec.

53, *Berners Street, W.*,
29*th April*, 1884.

Amount already announced £377 10s.

Omitted from the previous list:—Dr. Begley, £5 5*s.*; Dr. Habershon, £5 5*s.*; Mr. W. H. Freeman, £2 2*s.*

Received since the last announcement:—The Pathological Society, £50; The Obstetrical Society, £25; Mr. James Dixon, £10 10*s.*; Mr. Lawson Tait, £10 10*s.*

The following have sent five guineas each:—Mr. A. E. Durham; Sir William Gull, Bart; Dr. John Harley; Dr. Pavy; Dr. Quain; Dr. Radcliffe; Dr. Eustace Smith; Dr. W. J. Smith (Weymouth); Dr. Waring; Sir Spencer Wells, Bart; Mr. A. Willett; Dr. C. J. B. Williams.

The following have sent three guineas each:—Mr. Marcus Beck; Dr. Brodie; Dr. Church; Dr. Septimus W. Sibley; Mr. Knowsley Thornton; Dr. John Williams.

The following have sent two guineas each:—Mr. Henry Butlin; Dr. Buzzard; Dr. Cheadle; Mr. G. Cowell; Mr. Frederick J. Gant; Dr. Gee; Mr. Rickman Godlee; Brothers Mintern; Mr. Edward Newton; Mr. Robert W. Parker; Dr. Charles D. Phillips; Mr. T. Sympson (Lincoln); Dr. Reginald Thompson; Mr. Francis Vacher (Birkenhead); Mr. G. Wallis (Cambridge); Mr. Joseph Zaehnsdorf.

The following have sent one guinea each:—Dr. Allchin; Mr. Hamilton Cartwright; Professor Charcot; Dr. Cholmeley; Mr. Andrew Clark; Mr. N. Davies-Colley; Dr. Gairdner (Glasgow); Mr. Warrington Haward; Mr. H. G. Howse; Dr. Humby; Mr. Howard Marsh; Mr. John Merriman; Dr. Bernard O'Connor; Dr. Vintras.

The following have sent one pound each; Dr. Aitken, F.R.S.; Professor Esmarch; Dr. Hannover (Copenhagen).

Mr. J. B. Scriven, 10*s.*; Dr. John Candy, 5*s.*

W. Spry.—You will probably obtain them by applying at the College.

H. Marshall.—Papers on the subject will be shortly presented to the Houses of Parliament.

A Non-Crematonist.—Your letter is better adapted for our advertisement, than for our correspondence, columns.

APPOINTMENTS FOR THE WEEK.

Friday, May 2 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m.—Prof. Judd, "Krakatoa."

Saturday, May 3.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL INSTITUTION, 3 p.m.—Mr. H. M. Westropp, "Roman Archæology: The Forum."

Monday, May 5.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. C. Theodore Williams, Annual Oration, subject—"The Relation of the Medical Profession to other Professions." General Meeting and Conversazione.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 8 p.m.—Casual Communications by Messrs. Storer Bennett, E. G. Betts, J. H. Mummery; Mr. E. G. Betts will read a Paper on "Observations on the Teeth of certain Rodents."

ROYAL INSTITUTION, 5 p.m.—General Monthly Meeting.

Tuesday, May 6.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

MEDICO-PSYCHOLOGICAL ASSOCIATION, 4 p.m.—Quarterly Meeting, at Bethlem Hospital. Dr. Hayes Newington, "Unverified Prognosis;" Dr. Bonville Fox, "Exaltation in Chronic Alcoholism;" Dr. Mercer will move Resolutions in relation to the "Transference of Lunatics of Foreign Nationality to their own Countries." Council Meeting at 3.30 p.m.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. West, "Three Cases of Mediastinal Tumours;" Mr. Treves, "A Case of Supposed Actino-Mycosis;" Dr. Burney Yeo, "Cast from the Trachea;" Dr. Charlewood Turner, "Lardaceous (?) Syphilitic Supra-renal Capsule;" Mr. Sydney Jones, (1) "Multiple Exostoses. Exostosis and Loose Cartillage from the Knee-joint" (card), (2) "Stomach after Excision of Cancer of Pylorus" (card); Dr. Percy Kidd, (1) Myo-fibroma of Stomach," (2) "Tuberculous Ulceration of Pharynx" (card), (3) Polypoid Tumour of the Left Ventricle" (card); Mr. Lockwood, Cartilage containing Tumour of the Scalp;" Dr. Silcock, "Malignant Lymphoma of the Abdomen;" Dr. Carrington, "Misplaced Kidneys" (card); Dr. Hale White, (1) Atrophied Bones of the Arm after Post-Hemiplegic Rigidity" (card), (2) "Intestinal Obstruction from old Pelvic Adhesion" (card), (3) "Thoracic Aneurysm in a Woman" (card); Dr. Turner, "Pistol-shot Fracture of Cranium" (card); Dr. Hobson, "Malignant Disease of Cæcum" (card); Mr. Sutton, "Diseases of the Ductless Glands in Wild Animals" (card); Mr. Swinford Edwards, "A Cyst in the Ulnar Nerve" (card); Mr. Lane, "Specimen of Ununited Fracture" (card); Mr. Horsley, for Mr. Heath, "Recurrent Myxœdemomatous Tumour" (card); Mr. Knowsley Thornton, "Cystic Tumour of Spleen" (*recent*); Dr. Goodhart, "Tumour of the Pituitary Body of an Anutis" (card); Dr. Sainsbury, "Tubercle of Brain" (card); Mr. Alban Doran, "Broad Ligament Cyst developed above the Fallopian Tube" (card).

ROYAL INSTITUTION, 3 p.m.—Prof. Gamgee, "Nerve and Muscle."

Wednesday, May 7.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

OBSTETRICAL SOCIETY OF LONDON, 8 p.m.—Specimens will be shown by Dr. Cleveland, Dr. Matthews Duncan, Dr. John Williams, Mr. Alban Doran, and others. Papers—Dr. Arthur Mitchell, "Strong Mental Emotion affecting Pregnant Women as a cause of Idiocy in the Offspring;" Dr. Mathieson, "Case of Extra-Uterine Gestation—Delivery of Living Child per Vaginam—Removal of Placenta —Recovery."

Thursday, May 8.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 p.m. —Living specimens at 8 p.m. Dr. Stephen Mackenzie, "A case of Extreme Tortuosity of the Retinal Vessels;" Mr. Nettleship, (1) "Peculiar Changes in the Choroid after Papillitis," (2) "A case of Central Choroiditis;" Mr. Adams Frost, (1) "Ossification of Choroid, causing repeated attacks of Sympathetic Irritation," (2) "Recent Injury with detachment of Retina and Choroid," (3) "Detachment of Retina and organised Blood Clot after an old injury." Communications, &c.: Dr. C. E. Fitzgerald, (1) "An Instrument for showing the Action of Accommodation," (2) "On Acute Spasm of the Accommodation;" Messrs. Gunn and Anderson, "A case of Nerve Disease with Ocular Symptoms, including alleged Monocular Diplopia;" Mr. Higgens, "Remarks on Extraction of Cataract;" Mr. A. S. Morton, "Case of Hæmorrhage at Region of Macula;" Mr. Nettleship, (1) "Cases of Recovery from Amaurosis in Infants," (2) "Cases of Retro-ocular Neuritis;" Mr. Adams Frost, (1) "Ciliary Staphyloma, following Iridochoroiditis," (2) "Sympathetic Ophthalmitis subsequent to Excision."

ROYAL INSTITUTION, 3 p.m.—Prof. Dewar, "Flame," &c.

Friday, May 9.

CLINICAL SOCIETY OF LONDON, 8 p.m.—Mr. Clutton, "A Case of Intestinal Obstruction caused by a Diverticulum, successfully treated;" Mr. Christopher Heath, "Cases Illustrating the Treatmeant of Fracture of the Patella;" Dr. Whipham. "Case of Hydrocephalus of old standing, Insanity, Death;" Mr. William Anderson, "Case of Pyelo-Lithotomy;" Mr. Charters G. Symonds will show a case of "Ruptured Brachial Plexus."

ROYAL INSTITUTION, 8 p.m.—Prof. W. R. Smith, "Mohammedan Mahdis."

NOTE ON THE RELATIONS OF OVULATION AND MENSTRUATION.[1]

By LAWSON TAIT, F.R.C.S.

THE following extract is taken from one of the most important and most widely read text-books on physiology which has appeared in my lifetime, and it may be regarded as representing in its entirety the general belief on the matters referred to.

"The state of the female generative system during the continuance of menstruation appears to be analogous to the heat or periodic sexual excitement of the lower animals, some of which have a sero-sanguinolent discharge at that period, and among many of which the ova are entirely extruded by the female before the spermatic fluid of the male reaches them, this occasionally taking place even in birds. There is good reason to believe that in the human being the sexual feeling becomes stronger at the period of menstruation, and it is quite certain that there is a greater aptitude for conception immediately before and immediately after that epoch than there is at any intermediate period."

"The ova when set free from the ovaries by the rupture of the ovisacs and the giving way of their several envelopes, are received by the fimbriated extremities of the Fallopian tubes, which, during the period of sexual excitement, appear to be closely applied to the surfaces of the ovaries."

Finally, without exception so far, I have found the text-books assert that menstruation is the result of ovarian excitement due to the maturation of a Graafian follicle, and the readiness for the escape of its ovuli. If an exception is to be given, it is a doubtful one, and exists in the words of Carpenter, who says that "there is a periodic return of ovarian excitement, which *tends* to the maturation and extrusion of ovules, though it may not always reach that point; whilst there is also a periodic turgescence of the vessels of the lining membrane of the uterus, which *tends* to the production of a decidual membrane, but that these two periods, though usually coincident, are not necessarily so, and that either change may occur without the concurrence of the other."

I doubt if I have been able to understand this last quotation—I doubt very much if it can be understood; but it seems to me that the author having read Ritchie's account of the evidence which led up to his brilliant discovery, was unable to appreciate and accept it, and was equally unable to surmount its convincing logic.

The first extract I read to you contains, as I have said, an expression of the general belief concerning the relations between ovulation and menstruation, and it is in my belief wrong in every particular.

[1] Read before the Midland Medical Society, January 23rd, 1884.

The first statement that menstruation in woman is analogous to œstrus in lower animals is one which is entirely wrong, and from it many of the subsequent errors have sprung. In the last edition of my book on "Diseases of the Ovaries," I dismiss this question with the sentence, (p. 27) "that menstruation is a new feature in sexual life introduced high up in the scheme, and has no analogy to the œstrus or rut among the lower animals, is surely proved by the close reasoning of Arthur Farre (article "Uterus," *Encyclopædia of Anatomy and Physiology*)."

In such a work it was not necessary to argue this question at length, and in thus giving my authority I thought I had discharged my duty. Not so, however, think some of my critics. One of them recently, in a well-known English journal, has attacked me on my ignorance of the physiology of menstruation; and I am therefore disposed to make one more effort to uproot the mistaken views on menstruation still held almost universally, as if Ritchie, Kesteven, Farre, and Jackson had never written on the subject.

In the article I have just referred to, Arthur Farre shows that with the facts of congestion of the organs and periodicity of return, with an occasional coincidence of an extrusion of an ovum, as ascertained by a few rare *post-mortem* examinations, the analogy between menstruation and rut ends; and here I may add, that even in the matters of periodicity and congestion the analogy is faulty. The congestion which in women reaches such a degree as to permit of free loss of blood, in animals goes so far as to permit only of the exudation of a quantity of mucus for the lubrication of the passages and the discharge is rarely tinged with blood in some of the higher domesticated animals. In such an animal as the guinea-pig, where the whole process can be watched with ease, and where I have watched it in hundreds of instances, not a blood corpuscle can be found in the mucus, unless the examination be made just as the cohesion of the vestibule is being undone, that is, really before the rut has begun. The periodicity of the rut in animals is far too faulty to be compared with the regular menstruation of the majority of women.

Dr. Farre points out that it is during œstrus, and then only, that the females among the lower animals will receive the males. I may add to this, that there are some animals whose anatomy is so peculiar that it is possible for them to receive the male at the œstrus only. Thus, in the guinea-pig there is no vagina at all, save for about forty-eight hours, at the period of heat. It is also very well known that in many animals the male is equally affected, and that it is during the heat of the female only that semen is secreted by the male. Save during the œstrus of the female, the testicles of the male rat are hardly perceptible, whilst during this period they are of enormous size. "Now," says Dr. Farre, "with regard to the human subject, whatever may be possible during menstruation, yet essentially the intervals of the menstrual act are the times of fertility in women." This is absolutely proved by the fertility of the Jewish women, with whom intercourse is suspended for eight days after the appearance of menstruation, and in strict observers of Rabbinical rule for thirteen days.

The correlative statement made in the extract, with which I opened this paper, that it is at the menstrual period that women have stronger sexual desires, is one for which, I think, there is not the slightest foundation. It is manifestly a point on which it is difficult, almost impossible, to obtain evidence, either accurate or extensive; but what evidence I have been able to procure directly and very emphatically contradicts the statement. What I allude to is the statements of men with whom it has been necessary to discuss their marital relations, and I find that neither in man nor in woman is there any other than a distinct feeling of repulsion to the marital act during menstruation.

Here, then, we have not only an absence of analogy between œstrus and menstruation, but an absolute indication that they are distinct functions; and in women we have no indication whatever of an œstrus, so far as the sexual life is concerned. Let us see if we have any indication of it as far as the maturation and egress of ova are concerned, since these processes form prominent features of the œstrus of animals. The main question of the enquiry is really this: has the so-called ovarian excitement, alleged to arrive at the ripening of a follicle, anything to do with the process of menstruation?

Subsidiary to this is another issue raised by the consequent assertion that the follicular discharge occurs once a month. Finally, we have to give an answer to the very pertinent question of Dr. Reeves Jackson:— "Will the ovulation theory of menstruation stand?"

Toiling through the writings of physiologists and physicians previous to 1843, seeking for information on the development of our knowledge of the anatomy, functions, and diseases of the ovary, is, I think, one of the most unsatisfactory employments in which anyone can engage. It is perfectly true that, here and there, as in the pages of Morgagni, we get a perfectly accurate observation, yet, on the whole, the story is but a wearisome repetition of what we experience now-a-days. No sooner is a bacillus discovered, than it is ridden to death, and every disease is ascribed to its omnipotence and omnipresence. So was it in Leeuwenhoeck's time, that the discovery of the spermatic animalculæ raised a cloud of false theory, and still more false observation, the obstructive results of which have not yet passed away.

No completely accurate statement of the function of ovulation was made till the appearance of the papers by Dr. Ritchie, of Glasgow, in the old *London Medical Gazette* of 1843. These papers were epoch-making, and from them dates also the inception of accurate views of ovarian pathology. It has always been to me a matter of wonder that those papers have had so little influence. They have not been neglected; they have been and are now frequently quoted, and their conclusions have been often and I believe completely confirmed, yet the majority of the writers on physiology and gynæcology wander on as if the papers had never been published.

The papers are of the most business-like character; a dry detail of facts, and from the conclusions there is no escape. The first of these which may engage our attention is that "the ovaries of newly-born infants and of children are occupied sometimes numerously by Graafian vesicles or ovisacs, which are highly vascular as early as the sixth year, and vary in size from the bulk of a coriander seed to that of a small raisin; in the fourteenth year, at which time also they are filled with their usual transparent granular fluid, their contained ova can be detected, and their coats are so elastic that their contents on their rupture may be projected to at least twelve inches; the existence of menstruation not being essential therefore to these conditions, either as a cause of them, or as an effect, and the possibility even at this age, should rupture of the follicles occur, of their contained ova being conveyed to the uterus along the Fallopian tubes, kept patent by their peculiar secretion, will be admitted."

"The Graafian vesicles found in the ovaries prior to menstruation are found, as they also are in every other period of life, in continual progression towards the circumference of the glands which they penetrate, discharging themselves by circular-shaped capillary sized openings in the peritoneal coat, the presence of the catamenia being thus no indispensible pre-requisite to their rupture."

The establishment of menstruation does not neces

sarily give rise to any immediate modification in the manner in which the ovisacs are discharged, or in the subsequent changes which these bodies undergo. The ovisacs of the human female do not require the establishment or presence of menstruation for their development or rupture.

Graafian follicles of some size were found in the ovaries for fifteen years after the critical age, and the discharge of attenuated minute vesicles, apparently simple cells, from the surface of the glands appeared to terminate only with life.

Dr. Ritchie gives an extremely interesting account of the development of the ovular theory of menstruation having risen apparently in one of the essays of Sir Everard Home. When this author confined his original researches to hunting up some unpublished memoranda of John Hunter, he never went very far wrong, but when his originality was intrinsic his blundering became intense. Dr. Power, in 1820, assumed and apparently confirmed the correctness of Sir Everard, and various writers followed suit till an apparently genuine contribution appeared in the *Traitè Philosophique de Mèdecine Pratique*, by M. Gendrin, and established the theory. Dr. Robert Lee appeared on the scene and then began the great battle of the true and false *corpora lutea*, a battle based on the assumption of the ovular theory of menstruation, having for its object the establishment of a corollary as false as the main proposition, and constituting a quarrel as bitter, as fruitless, and as foolish as any to be found in the record of medical amenities. The struggle was only fading away when I entered college.

During the whole of the controversy upon these two points, lasting over fifty years, of course there were innumerable experiments upon animals. That these experiments were wholly useless is beyond doubt, and that they were entirely misleading is now universally admitted. Lest I should be charged with expressing a prejudiced opinion on this much debated subject, I shall content myself with quoting the *ipsissima verba* of Dr. Ritchie, written in 1842; "but unfortunately for science, and for multitudes of suffering quadrupeds sacrificed in a mistaken line of investigation, this conclusion did not happen to be verified by actual dissection." He further on speaks of the various misconceptions to which this method of investigation gave rise, and shows conclusively that by no experiments on animals could the enigmas of human ovulation and menstruation be solved. It was by *post-mortem* dissection that he made his discovery, and it is by *ante-mortem* dissection that I am in a position completely to confirm it.

After Ritchie's papers, the next contribution in order of date is in the *Medical Gazette* for 1849, by Mr. W. Bedford Kesteven, a very well known practitioner in the north of London, still living, I am glad to say, in honourable and well deserved retirement. Mr. Kesteven has made some notable communications in the direction of original research, and though there is little that was really new in the paper now under notice, it confirmed the views of Ritchie in very terse and convincing language. Thus, in answer to the one argument used against Ritchie, that in a few instances follicles had been found either just ruptured, or on the point of rupturing in women who had died during menstruation, Mr. Kesteven says, "As ovulation is a constant function of the ovaries, and menstruation an occasional function of the uterus, the two may be expected to be found occasionally concurrent."

He also points out that if the maturation of ova occurred as the rule at the menstrual period, pregnancy would not occur so often as it does in the absence of the catamenia, as in the amenorrhœa of lactation and other conditions. He also argues from the case of the Jewish people with such force that I give his words in full.

"According to the Mosaic law, sexual intercourse is prohibited until after the eighth day after the appearance of the catamenia; to this strict Jewesses add five days more in obedience to a Rabbinical precept, and yet these women are equally if not more prolific than other females. Thus, if the ova be discharged only at the monthly period, these individuals become pregnant before the discharge of the ova. But the rigid observance of these injunctions by a large number of Jewesses, coupled with the known experience of accoucheurs generally, that impregnation may and does take place immediately before the menstrual periods, affords a much stronger proof that the maturation of ova occurs at any time, than the occasional and infrequent observation of recently ruptured ovisacs concurrently with menstruation affords of the menstrual flow."

Mr. Kesteven's statement about the general experience of accoucheurs is confirmed in Merriman's synopsis.

I have made a very diligent search for other contributions to this subject in the medical literature of the last 25 years, but with singularly barren results. Everywhere I am met by the accepted tradition that menstruation is due to the period of ovarian excitement due to the ripening of a Graafian follicle, and that the termination of this is the grasping of the ovary by the infundibulum of the oviduct at the precise spot where the follicle is ready to burst.

Here and there, however, an occasional authority breaks away from the tradition, and gives an independent statement. Thus, Professor Hirsch (*Schmidt's Jahrbuch* for 1850), concludes that menstruation in women has no analogy with the heat of beasts, that fructification can be accomplished at any time, not at the period of menstruation only, as in the lower animals, and that the function of the ovary is to be continually producing mature ova.

In the *Archives de Physiologie* for May, 1874, Dr. K. Slavianski states, as the result of his observations, that the development and maturation of the Graafian vesicles do not take place in any regular periodical fashion, and that there is no connection between these conditions and menstruation. This latter physiological phenomenon is entirely independent of the former.

Dr. De Sinèty, to whom we owe an immense debt for the elucidation of very many important points in the anatomy, physiology, and pathology of the ovary, in a paper communicated to the *Société de Biologie* on December 2nd, 1876, narrates a case of great importance by which menstruation without ovulation is established.

Dr. A. Reeves Jackson published a very important paper in the *American Journal of Obstetrics* for October, 1876, in which he summarised what had been done by Ritchie and others, and he deals in a most forcible fashion with some of the more recent advocates of the ovular theory. Thus, at page 147 of Dr. Robert Barnes' book on "Diseases of Women," is a series of facts given, but singularly perverted, and of this kind of treatment Dr. Jackson most justly says, "Such a course as is indicated in the foregoing instances, is more reprehensible than reasoning without facts; it is reasoning against them. Yet these are only samples of the sort of argumentation which is frequently found in connection with this subject."

He sums up in a sentence the experience of ovariotomists in which I entirely concur, and the quotation of which will spare me saying much more on this point. It is their experience, he says, that in many cases in which both ovaries have been removed, those organs have been found so thoroughly diseased as to preclude the idea that they could possibly have performed their

functions of ovulation normally, if at all, and yet the regularity of menstruation has suffered no interruption. To this I may add, that the most diligent search in the ordinary cystic ovary has failed ever to discover ova in the cysts, with the exception of three cases, clearly of a special variety of tumour described by Rokitansky, Ritchie (younger) and myself. This ova-bearing kind of tumour is fully described and figured in my last edition.

Dr. Jackson brings most valuable evidence on the subject from an examination of cases of hernial ovaries. In a case of Dr. Oldhams', published by the Royal Society, the periodic enlargement of the glands due to the process of ovulation, as was reasonably supposed, occurred at irregular intervals from three weeks to three months.

In another case of Dr. Meadows', the tumour increased in size, and became painful at every menstrual period, but when it was removed it proved, according to Dr. Meadows, to be a cystic tumour in which "there were no proper Graafian vesicles to be seen."

Dr. Jackson proceeds to show, from a mass of material drawn from numerous sources, that (*a*) menstruation goes on under a variety of circumstances under which ovulation is wholly impossible; and (*b*) conversely that ovulation may occur without accompanying menstruation.

Further, quoting Goodman and others, he shows that the statements of Barnes, Leishman, Spencer Wells, and others, to the effect that removal of both ovaries arrests menstruation are entirely wrong. He goes so far as to say that men who make such a statement now subject themselves to charges either of ignorance or want of candour. With this I quite agree, for I have added to the evidence abundant proofs that removal of the ovaries without injury of the tubes has often no influence on menstruation at all, that removal of the tubes, even when the ovaries are left, arrests menstruation in the great majority of cases, but that (as in one of Baker Brown's cases) even removal of the ovaries, tubes, and greater part of the uterus may not arrest or influence in any way the menstrual periodicity.

In the *British Medical Journal* for 1881, I published a letter, in which I said, that "Evidence is rapidly accumulating in my hands pointing to the conclusion that ovulation and menstruation have no necessary connection; and that *corpora lutea* are not a necessary result of the maturation and shedding of true ova."

At page 25, in the last edition of my book on the "Pathology and Treatment of Diseases of the Ovaries," I give the following summary of my conclusions:—

"I have, during the last few years, had the opportunity of seeing the ovaries of a number of women whose abdominal cavities I have had to open for various conditions not connected with diseased ovaries, and I have always found that during menstruation the tube is fastened on the ovary, whether there be a ripe follicle at the point of adhesion or not; that both tubes were generally fastened to their respective ovaries, though in one ovary there may have been no appearance of a ripe ovisac; that I have very frequently seen a ripe ovisac on the point of bursting, or just burst, when the patient was midway between two menstrual periods. Finally, I have removed in two cases ovaries with the tubes fastened on them, during menstruation, in none of which were there any ovisacs approaching ripeness."

The chief purpose in the present paper is to draw attention to the above conclusions by giving in detail the evidence upon which they are based, conclusions which are being strengthened as the evidence accumulates.

First of all let me say that abdominal surgery affords abundant opportunities of settling a question such as this; indeed, it is not creditable to the art that its settlement has been so long in abeyance. Sir Spencer Wells has performed over a thousand ovariotomies, in the great majority of which a healthy ovary was left. In the performance of the operation it was his duty to ascertain that the second ovary was healthy, and if the simple expedient had been resorted to of noting the appearance of the organs and the time of the menstrual month in which the operation was performed in each case, the ovular theory of menstruation would have been settled long ago.

The custom arose in the removal of an ovarian cystoma of selecting the time for the operation as nearly as possible equi-distant from two periods. There was no really good reason for this, and in some cases arguments against it might be found. But when abdominal sections came to be performed for other purposes, such as the removal of the uterine appendages for bleeding myoma, pyo-salpinx, or chronic ovaritis, it soon became evident that it was best to operate just before or even during the menstrual period. The reason of this is that by this selection the patient is saved the pain and loss of blood of an additional period, for the operation brings on a period almost always, and if one is made to do for two, it is better. In the case of myoma there is the additional argument that the rest between the last period and the operation should be as long as possible. It has, therefore, come to me to be a rule to select the immediate approach of menstruation as the time for operation in many cases, and to be in others quite indifferent on the subject.

In the evidence about to be given in detail, I have not thought it worth while to tabulate the cases of double cystoma, because they go almost in a block to support the views of Ritchie. In a very few cases of double cystoma, and equally so in a few cases of single cystoma, the disease is associated with the arrest of menstruation, but in the great bulk of the cases menstruation goes on uninterruptedly. No one has yet claimed, save in the three published cases of Rokitansky's peculiar tumours, to have found ova in the cavities of ovarian cystoma, nor do we ever see anything like a ripening follicle; and in Rokitansky's tumours the ova are retained, not discharged. We must conclude, therefore, that in those cases of double ovarian cystoma, in which menstruation goes on during the growth of the tumour, that process cannot in any way be dependent on the ripening and discharge of ova.

In cases of single cystoma, the argument for one ovary, that is half the work of ovulation, is just as conclusive. If menstruation depended on ovulation, we ought to expect that, during the growth of a single tumour, about half the periods ought to be suppressed, but they are not. In such cases, the condition of the healthy ovary is a matter of interest, and therefore I have noted it. Probably cases of parovarian tumours will prove to be the most satisfactory field for this enquiry, as in them the uterus and its appendages are wholly free from disease.

In the following narration, all cases of irregular and deficient menstruation have been omitted, as also all cases where the history was defective:—

1 August 7th, 1880.—Cirrhotic ovaries removed, age 31; menstruation regular, not a trace of vesicles of any kind in the glands; had menstruated five days before the operation.

2. August 10th.—Cirrhotic ovaries removed, age 28; menstruation regular, only one old vesicle to be found; had menstruated thirteen days before operation.

3. August 17th.—Appendages removed for severe menorrhagia, age 49; operation performed immediately after menstruation; one follicle about half matured, no trace of one having recently burst.

4. September 1st.—Right ovary removed for cystoma, age 17; operation performed midway between periods;

no trace of recently burst nor of ripening follicle in remaining ovary.

5. September 1st.—Appendages removed for bleeding myoma, age 47; both ovaries cystic, and entirely without traces of normal vesicles; the hæmorrhage was periodic (menstrual), and lasted from ten to twelve days.

6. September 24th.—Appendages removed for double pyo-salpinx, age 28; menstruation had been regular, profuse, and intensely painful; the tubes were glued on to the ovaries, and no vesicles could be found in the latter.

7. October 5th.—Appendages removed for double hydro-salpinx, age 32; menstruation had been regular, profuse, and intensely painful; both ovaries were disorganised by chronic inflammation, and no vesicles of any kind could be discovered in them.

8. October 6th.—Parovarian cyst, age 48; had not menstruated for a year; one well-marked follicle observed in left ovary.

9. October 12th.—Appendages removed for menstrual epilepsy, age 23; operation performed four days before an expected period; one follicle had just burst (probably did so during the operation) in the right ovary, and another was nearly ready in the left ovary.

10. October 26th.—Appendages removed for menorrhagia due to myoma, age 35; operation performed midway between the periods; one large follicle quite ripe in left ovary, another not so far advanced, and two evident, though smaller, in right ovary.

11. December 7th.—Left ovary removed for cystoma, age 21; operation performed just after a period; follicle recently burst in right ovary.

12. December 18th. — Appendages removed for menorrhagia, age 44; operation midway between periods; fully ripe follicle in right ovary, ruptured when grasped, and shed yellow body; one immature follicle in left ovary.

13. January 13th, 1881.—Appendages removed for myoma, age 32; operation performed during menstruation; both tubes grasping the ovaries, but no follicles ripe.

14. February 5th.—Appendages removed for myoma, age 41; menstruation regular and very profuse; operation performed between the periods; both ovaries cystic, and no follicles apparent anywhere.

15. February 12th.—Appendages removed for most terrible menorrhagia, due to myoma, age 43; operation performed just before a period; no traces of follicles anywhere.

16. February 17th.—Left ovary removed for cystoma, age 23; menstruation quite normal, operation performed just after a period; one immature follicle in right ovary.

17. March 2nd.—Removal of appendages for persistent menorrhagia, age 25; both ovaries cystic, but of small size; no follicles discoverable.

18. March 20th.—Appendages removed for myoma just before menstruation, age 35; a fully ripe follicle in right ovary, and one almost as advanced in left.

19. March 29th.—Left ovary removed for cystoma, age 30; operation performed twelve days after period; fully ripe follicle in right ovary, and two others ess mature.

20. June 15th.—Both tubes removed for myoma, ovaries being left, age 43; the right ovary was not seen, but the left had an almost ripe follicle; the operation was done almost midway between the periods; the patient has never menstruated since, and the myoma has almost disappeared.

21. July 2nd.—Right ovary removed for cystoma, age 38; menstruation regular; operation performed four days after period; when left ovary was being examined, a fully ripe follicle burst.

22. August 8th. — Parovarian cyst of right side removed about eight days before period; an almost ripe vesicle was noted in left ovary; no vesicles at all in the right.

23. August 19th.—Appendages removed for pyo-salpinx, age 27; operation performed the first day after menstruation; no traces of follicles in the disorganised ovaries; menstruation had been regular and profuse.

24. August 22nd.—Right ovary removed for cystoma, age 18; menstruation just over; no trace of follicle in left ovary.

25. August 25th. — Appendages removed for persistent menorrhagia, due to myoma, age 38; both ovaries cystic; no trace of normal follicles.

26. September 17th. — Appendages removed for myoma with persistent menorrhagia, age 40; both ovaries cystic; no trace of normal follicles.

27. November 14th. — Removed appendages for hydro-salpinx, age 33; operation performed during menstruation; no trace of follicles in either of the ovaries.

28. November 22nd. — Left ovary removed for cystoma during menstruation, age 22; tube fastened on to right ovary, in which there was a follicle apparently quite ripe, but away from the tube at least half an inch.

29. November 30th. — Appendages removed for hydro-salpinx, age 37; operation performed midway between periods; no traces of follicles in the ovaries; the patient has menstruated regularly ever since, more than three years.

30. December 19th. — Appendages removed on account of intense pain produced by dislocation of ovaries into the *cul de sac*, age 29; operation performed about midway between periods; a perfectly ripe follicle in each ovary, both of them discharging their contents during operation.

31. January 4th, 1882.—Appendages removed for persistent menorrhagia, due to myoma, age 36; operation performed about ten days after a period; a perfectly ripe follicle in one ovary, several quite immature in the other.

32. January 10th.—Appendages removed for myoma, age 37; operation performed during menstruation; each ovary was grasped by its tube, but there were no ripe follicles.

33. January 29th.—Appendages removed for myoma, age 46; the left ovary was grasped by its tube, and very near the point of grasping was a perfectly mature follicle, but the ovum on its escape, when the follicle ruptured, could never have been passed into the tube.

34. February 18th. — Appendages removed on account of persistent pain, age 43; operation midway between periods; ovaries quite cirrhotic, and not more than one-third of the normal size; menstruation had been perfectly regular, and normal in amount; there were traces of vesicles throughout the ovaries. The removal of appendages arrested menstruation, and has cured the patient.

35. February 22nd. — Appendages removed on account of persistent pain and excessive menorrhagia, due to chronic pyo-salpinx, age 27; no trace of vesicles could be found in the ovaries; they were quite disorganised.

36. March 16th.—Appendages removed on account of persistent pain, age 33; menstruation regular; operation performed just after a period; not a trace of vesicles in the ovaries, which were shrivelled and deeply grooved in all directions.

37. March 31st.—Appendages removed for myoma, age 40; operation performed on second day of menstruation; ovaries both cystic; no normal vesicles, nor any appearance of embracement of the ovaries by the tubes.

38. April 5th. — Right ovary removed for large myoma, age 33; menstruation regular; operation

*

eighth day after period; perfectly ripe vesicle in left ovary.

39. April 20th.—Appendages removed for myoma, age 21; operation performed during menstruation; both ovaries grasped by tubes; no ripe follicles in either ovary.

40. April 25th.—Appendages removed for menstrual epilepsy just before a period, age 25; ovaries contained a few cysts, but no follicles approaching ripeness.

41. May 5th.—Parovarian cyst removed ten days after period, aged 28; patient pregnant two months; a perfectly ripe vesicle in right ovary.

42. June 24th.—Parovarian cyst removed on third day of menstruation; right tube embraced its ovary, a ruptured follicle in left ovary, but left tube did not seem to be anywhere near it.

43. July 21st.—Left ovary removed for cystoma, age 22; operation performed eleven days after menstruation; a perfectly ripe follicle in right ovary, which burst and discharged its contents when handled.

44. July 24th.—Appendages removed for persistent pain, age 32; ovaries adherent and quite disorganised; no trace of follicles in them; menstruation had been perfectly regular and profuse.

45. July 25th.—Appendages removed for persistent pain, age 37; ovaries adherent; several follicles found in right ovary, but not approaching ripeness; operation performed four days after period.

46. July 27th.—Left ovary removed for cystoma, age 38; menstruation had been quite regular, and patient had borne the last only two years before the operation; there was no right ovary in this patient.

47. October 7th.—Parovarian cyst removed during menstruation, age 26; left tube embraced its ovary, but no follicle on that side; a perfectly ripe follicle in the right ovary.

48. November 6th.—Parovarian cyst removed, age 44; operation on third day of menstruation; both ovaries grasped by their tubes, and under the left tube there was clearly a ripe follicle.

49. January 28th, 1883.—Parovarian cyst removed on second day of menstruation, age 29; no embracement of ovaries and no ripe follicles in the ovaries.

I made no notes of further observations, as I began to lose interest in the enquiry, being perfectly satisfied that the evidence so far has completely destroyed the ovular theory of menstruation. I am persuaded, however, that it is worth further perseverance, as I am not sure that some of my other conclusions are quite as secure, and therefore I shall resume it.

As it stands, the evidence seems to me conclusive on the one point for which it was taken. Of course different people read the same evidence in different ways, and probably it will be so here; but in dividing the cases into three of the simplest and most natural groups, it seems to me that they arrange themselves as follows:—

1. Cases, nine in number, where it was evident that menstruation and ovulation were concurrent (Nos. 9, 11, 18, 21, 28, 33, 42, 47, and 48).

2. Cases of negative proof against the ovulation theory of menstruation, fifteen in number (Nos. 1, 2, 3, 4, 5, 6, 7, 10, 12, 13, 19, 22, 29, 38, and 45).

3. Cases, twenty-five in number, affording positive evidence against the theory (Nos. 8, 14, 15, 16, 17, 20, 23, 24, 25, 26, 27, 30, 31, 32, 34, 35, 36, 37, 39, 40, 41, 43, 44, 46, and 49).

Taking the average period of menstruation to be one-seventh of the month, and if we assume my theory of continuous ovulation to be correct, out of 49 observations we ought to have seven instances of ovulation observed during the menstrual period, and in the above table we have nine cases of menstrual ovulation. The close correspondence of these figures is not conclusive, but it is very suggestive that the association was one of mere coincidence.

In such a case as this the want of proof is quite as strong for the purpose of a presumption as the presence of direct testimony. To the twenty-five cases of positive evidence against the ovulation theory of menstruation we must really add the fifteen negative cases, and then we know the overwhelming case against the theory that out of a continuous and consecutive series of observations we have the theory inapplicable in nearly 82 per cent. of the cases. To this also must we add the negative evidence of the cases of cystoma.

Should further research confirm these conclusions, the ovular theory of menstruation must be given up; and in conclusion I must point out two curious inconsistencies between the facts of my observations and the theory I have been discussing. From the appearance in Case 9 it might happen occasionally that menstruation should occur twice within a very few days, with perfectly healthy uterus and ovaries, for in that case and in others it was quite clear that two ova would be discharged within a few hours of each other.

The second inconsistency is that the most marked and proper menstruation has been in cases of disease of the tubes, just as the most profuse lachrymation occurs in inflamed eyes; but in these cases, as a rule, not only is there no ripe vesicle to be seen, but the ovaries are generally so disorganised that no vesicles of any kind are visible. These conditions clearly show that the ovaries have little or nothing to do with menstruation, and render it highly probable that the tubes are largely concerned in it.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Epidemiological Society of London.

(*Continued from page* 519.)

I HAVE now published in the *Medical Times and Gazette*—January 4th, 1879, to April 18th, 1884—what I regard as the *First Volume* of this work, comprising *Indian Fevers*. The Second Volume, completing the treatise, stands nearly ready in MS. As I find that I have noticed the whole of the diseases prevalent throughout India, I have dropped in my title the words "*Especially those prevalent in Bengal.*"

Note on the Beriberi, or the "Kakké," of Japan.

I am indebted to the kindness of Surgeon-General C. A. Gordon, for a sight of Dr. Duane B. Simmons's elaborate report.[1] The author defines beriberi as a disease occurring during the summer months, especially in the seaport towns on the eastern and southern coasts of the Japanese islands, chronic as to form, but subject to exacerbations of varying degrees of severity, having for its characteristic symptoms anæsthesia of the skin, hyperæsthesia and paralysis of the muscles, anasarca, palpitation, cardiac and arterial murmurs (in the wet form), præcordial oppression, abdominal pulsation. It has two distinct forms, the wet (*beriberia hydrops*) and the dry (*beriberia atrophia*); cases of both are met with in the same locality, the former more frequently when the summers are attended by an unusual amount of rainfall and moisture, and the latter when the season is of unusual dryness. The wet form is by far most to be dreaded, as it frequently runs a rapidly fatal course in defiance of all known modes of treatment. The dry form is rarely fatal.

[1] China Imperial Maritime Customs II. Special Series, No. 2. Medical Reports for the half year ended 31st March, 1880, 19th Issue, page 38.

Dr. Simmons' report will, I think, in the future, be most useful to those who may undertake the investigation of the disease in its more chronic endemic forms. He does not appear to recognise the disease in its epidemic form. In his histories, an early stage of fever does not appear to have been at all generally looked for, but Case I. has the following early history: *Pernicious Beriberi; Death.* "Entered the hospital 15th June." "During the first days of May, began to feel unwell, had occasional slight chills, followed by heat flashes" (flushes?), "a general sense of *malaise*, and a tired feeling in the legs." The following remark appears to show that kakké does commence as fever. Dr. Simmons' observes (p. 68) that, notwithstanding the strong resemblance which exists between marsh malarial fever and beriberi, their admixture is uncommon. "They have a certain resemblance in their initial stages which is very puzzling, and, though we may be able to diagnose with certainty beriberi or malarial poison as the cause of the indisposition, nothing but the administration of quinine will for some days enable us to decide which it is." Upon this I must state the platitude that this or any other disease which for days runs such a course that the QUININE TEST alone enables us to differentiate it from "Marsh Malarial Fever" must be, unquestionably, *a fever.* The author continues: "The almost invariable low temperature, in uncomplicated cases, is commonly noticed by all recent observers. So well established is this point that it is of decided diagnostic value in doubtful cases." There is no mention of an exanthem, but I apprehend that, in those cases where patients with beriberi are "attacked with typical typhoid fever," the eruption is not wanting. "In the wet form of the disease the urine is always less in quantity than normal. It is rarely high-coloured and is without albumen." I think that a full and patient enquiry into the febrile stage of kakké is still most desirable.

Prefixed to Dr. Simmons' report is a map:—When we recollect that beriberi has appeared in Brazil, and that it occurred in H.M. ship *Juno*, at Sydney, after a lengthened cruise among the islands in the Pacific, we perceive that the influence of beriberi may be regarded as encircling the globe between the limits of the Japan Islands, 37° N., and of Sydney, 33° 59′ S.

Malignant Asiatic Cholera and Cholera Simplex have been commented upon in Vol. II. for 1883, pp. 208, *et seq.*

Diphtheria and Croup.

He who would hope to throw a clear light upon the nature of the disease or diseases which, early in my career, used to be placed under these designations, ought to be an antiquarian as well as a pathologist. In this enquiry, it is to be asked, (1) How far these diseases used to be accurately differentiated forty years ago; and (2) Have changes since taken place in their type? I shall consider three points very briefly; but, having been in youth a victim to the neurosis laryngismus stridulus, or spurious croup, I may claim the questionable advantage of having some practical insight into this question—(1) It is certain that many observers, misled by the formidable character of the symptoms of false croup, have mistaken their cases of this disease for examples of the "membranous" exudative type. An eminent authority on Indian disease wrote as follows, five and thirty years ago:—"Croup is a most frightful disease, attacking the strongest children, and attended with the most agonising and convulsive efforts at respiration. It comes on quite suddenly, often in the middle of the night, and requires prompt attention and careful watching: for real inflammation of the larynx is apt to follow it. In common cases, however, all this hard barking clangor disappears after an emetic and a sleep." How came this generally very thoughtful pathologist to designate as "croup" that which, by his own showing, was merely the ordinary type of laryngismus stridulus—spurious croup. Some years before his remarks were published, another Calcutta authority took a more just view of the case,[2] observing, "Spasmodic croup is a disease common to infancy from one part of India to the other, and not unfrequent at the Presidency" (Calcutta). "Dr. H. H. Goodeve must have been often summoned from his couch to prescribe for this disorder, and to quiet the alarm of agitated parents. This, in appearance, is a very alarming disease, but is not dangerous unless neglected, and is very tractable." "The characteristic symptoms are—loud wheezing and difficulty in breathing. This disorder attacks suddenly, and generally between 11 at night and 2 o'clock in the morning, frequently precisely at midnight. The child starts from its sleep with the loud wheezing which may be heard throughout and without the house; we have known the sentry outside give the first alarm to the slumbering domestics. The child generally sits up in bed, and cries more from fright than pain or difficulty in breathing. There is a predisposition in some families to this complaint, every child being subject to it. Dentition predisposes to it. Disorder of the bowels acts sometimes as a remote and occasionally as a predisposing cause. It is common in India, from the Himalayas to the sea, though it seems to be more so in the Upper than in the Lower Provinces; and in some parts of these it occurs more frequently than in others. We would instance Rohilcund. During a residence of four years at Bareilly, we met with more cases than during an equal length of time in any other part of India. Its attacks are more confined to the cold season, or to the months ushering in the commencement and termination of this period of the year; we would fix upon October and March, when there is the greatest range of the thermometer in its diurnal changes, as the months in which it most frequently occurs, and for this reason probably the disease is more frequent in the Upper than in the Lower Provinces. We believe that, like inflammatory croup, it is often excited by a cold northerly or easterly wind, or by a wind blowing across a tank or river." The writer adds, that he knew of only one fatal case—a young infant died of convulsions, to which it was predisposed from a weakly constitution inherited from a delicate parent.

(2) Has any change taken place in the type of this class of diseases within the last forty years? I can declare positively, from my own personal and professional experience, that no material alteration has occurred in the type of spurious croup within that period. If membranous croup be diphtheria, its type may have undergone some change in Europe and in India; but I do not know that we have evidence of such change. We have always been told, until lately, that true croup attacks the healthiest children, and that it is essentially a "sthenic" disease, attended with high fever. Mothers used not to be pleased when the healthy appearance of their young children was remarked. "Yes," it would be said, "such children are very liable to croup!" In the first quotation given above, we see it emphatically stated that the disease "*attacks the strongest children.*" Here it is to be borne in mind that, although I think it will be found that subjects of spurious croup are mostly rather pallid and deficient in muscular power, very fine-looking children suffer from this neurosis. Again, has there ever been a "sthenic" type of diphtheria? I think not; but my experience in India — where the strongest Europeans have not always a very robust appearance—shows that many of the healthiest-looking people fall victims to diphtheria. A lady, who

[2] Finch's *Ind. Jour. of Med. and Phys. Science*, vol. ii., p. 428.

appeared to be in the enjoyment of the most perfect health, was attacked with diphtheria in Calcutta. I opened the trachea of a most beautiful and healthy-looking little European boy of four, almost *in articulo mortis* from diphtheria, whom one of my colleagues requested me to take charge of. At the Medical College, ten years ago, the youngest and apparently the most vigorous of our staff succumbed to diphtheria. This disease may attack the strongest, but it is not, on that account, "sthenic;" further, those who to ordinary observation appear to be the most robust are often weak —*Nimio ne crede colori.* I am strongly inclined to believe that true croup "has always been diphtheria of the air passages, and that the natural destructiveness of the disease was, generation after generation, largely aggravated by heroic, depletory, and depressant measures, employed under the false idea that the malady is "sthenic;" while many a little weakly but flushed-faced victim of spurious croup, who would have been asleep and well by sunrise had he been properly treated, has been bled, leeched, and blistered to death. Until treated, the subjects of spurious croup are generally feverish and flushed, but the skin acts freely after ipecacuanha and a warm bath. There is no inflammatory fever; no organic disease whatever throughout the progress of this neurosis.

Writing in 1860, Morehead did not allude to diphtheria or croup. Hence I infer that he had not seen the former and did not believe in the latter as a distinct entity. In his book, published four years later, Dr. Peet states that, "in the Western Presidency of India diphtheria in an epidemic form is quite unknown." Peet "never met with nor heard of croup in a native child in India," and he held that "it may, without hesitation, be affirmed that native children in Bombay," and "perhaps in other parts of tropical India, are quite exempt from this disease, whilst resident European children are frequently attacked." I do not, however, infer confidently from his description that this authority was able to draw a clear line of differentiation between "true sthenic membranous croup" and "spurious croup."

Mackinnon considered that croup is far less prevalent in India than in colder climates. Writing in 1855,[3] he cited an account of an outbreak of croup (?) which had just occurred at Darjeeling. During the first sixteen years of the occupation of that hill station as a sanatorium, croup had never shown itself, except on one previous occasion. The superintendent of Darjeeling called the outbreak "the infantile epidemic," and denied that it was a croup epidemic. Croupy symptoms did not appear at the beginning. There was "an epidemic in which the mucous membrane of the fauces, throat, larynx, and trachea was affected in various degrees of intensity, from malignant sore throat, fatal in one boy of seven years, and croup with a false membrane, fatal in two cases under five years of age, to the slightest coughs, colds, and sore throats, which were general among half the children of the place. Here diphtheria and croup are, to say the least, simultaneously incident upon a small community. Total of children, say 90. Here, too, we cannot but observe the alliances of this expression of disease on one side, to diphtheria, and, on the other, to the epidemic bronchitis of children in Lower Bengal, described under the heading of *Influenza.*

I have seen many cases of diphtheria of the air passages, and three marked cases of "membranous" laryngitis; but I never saw a case of sthenic "membranous croup" of the kind described in text books of medicine some years ago. In none of my cases was the "brassy cough" present; but in all there was more or less of that harsh sound which is fairly represented by breathing hard and blowingly through the tube, made by bringing the last phalanx of the thumb against the backs of the last phalanges of the fingers. The hill station of Nynee Tal long had an evil reputation for croup. Dr. Francis states, from three years' experience, that the children there were very liable, in the spring and autumn, to "attacks of bronchitis, croup, influenza, and cynanche." He observed that in 1855 "*croup of a sthenic character*" (the italics are mine) "and bronchitis were epidemic at both the above seasons; whilst there only occurred two or three cases of simple cynanche tonsillaris. But, in September, 1856, the cynanche cases were more numerous, and in one family, they assumed a decided diphtheritic character. Here, again, we notice a close approximation of cases of "true croup" (diphtheria of the air passages?) and of ordinary diphtheria.

I, as I have said, suffered much in childhood from neurotic spurious croup, and I saw a great deal of that disease among children in Bengal. One damp and stormy night, at a boarding-house in Calcutta, I was busy placing one of my own children, violently attacked with spurious croup, in a warm bath, when I was urgently called to see two children of an officer, in the next apartment, who were similarly attacked. The same hot water kettles served for both families. I passed nearly the whole of one night at Bishop's College with a very fine boy, the son of a clergyman. The boy looked so healthy, and was so hot and flushed, and the cough had so loud a brassy clangor, that I, for some hours, doubted whether I had not, at length, met with a case of genuine sthenic membranous croup. Treatment, however, showed that it was merely the neurosis. We place the child in a warm bath, wrap it in a blanket, make it vomit with ipecacuanha, and give it a brisk purgative (in these cases, and almost in these alone, I gave calomel, which acts very kindly). Sleep generally follows vomiting, and, when the cathartic acts, the child is well, but rather weak.

Although nearly up to the time of my entrance to the Indian Service in 1848, I was an office bearer at the Pathological and South London Medical Societies, and a steady worker at other societies, and visited Guy's Hospital almost daily, I knew very little indeed of diphtheria, except that which I learnt from French authorities on the *Diphthérite* of Bretonneau. I first saw typical cases of this disease in India. According to Kenneth Mackinnon, diphtheria "seems to have first shewn itself in Calcutta in 1852, when it destroyed several children at the Martinière School and elsewhere."[4] Although this school is a very fine building, it stands almost at the extreme east of the city—a position which has always been regarded as unfavourable. The close vicinity of a very extensive and full Mahomedan burial ground was another evil, but Dr. Webb attributed the outbreak to the foul state of the drains, and to the presence of numerous sheep pens in the immediate vicinity.

Mackinnon says that it appeared again in 1855 in Calcutta, but not in the same locality. He mentions that there had been one fatal case, a most sudden and afflicting visitation, occurring in a young married lady. He knew of another young lady, from whose fauces flakes of the exudation were removed by the forceps. From that time sporadic cases, with a distinct tendency to spread in families, have rather frequently occurred in Calcutta; but, as far as my own observation extends, there has not been an epidemic outbreak in that city. It is, however, very noteworthy that, a year later, 1856, diphtheria attacked four members of a family resident at Nynee Tal, a delightful hill station at an elevation of 6,450 feet above the level of the sea,

[3] *Ind. An. M. S.*, No. 5, p. 131.

[4] "On the Epidemics of Bengal and the North-West Provinces," *Ind. An. Med. Sc.*, No. 3, p. 176.

upwards of 600 miles north-west of Calcutta.[5] Nearly every Indian writer on diphtheria moots the question, *Is this disease closely allied to scarlatina?* Mackinnon states the barely note-worthy fact, that one of the Calcutta young ladies mentioned above as suffering from diphtheria in 1855, had a scarlet eruption, not preceded by fever, some weeks after recovering from the throat affection."

The late Dr. Peet, of Bombay, states,[6] that during a severe epidemic of scarlet fever, which raged in the southern part of Australia in the year 1853, diphtheria was very prevalent and fatal; and, indeed, in some of the cases which he saw, it was difficult to say which of those diseases was present. Until scarlet fever was introduced into Australia, diphtheria had never occurred there. He adds that, in the Western Presidency of India, where scarlet fever did not prevail when he published his work in 1864, diphtheria in an epidemic form was quite unknown.

Dr. Francis witnessed an outbreak of diphtheria at Warley Barracks in 1857, scarlet fever being epidemic at the same time. He alludes to this after describing the four cases of diphtheria which he saw at Nynee Tal, where no suspicion of the existence of scarlatina existed. He suggests the question: Is diphtheria scarlatina without the eruption?—a question which, I believe, most observers will answer in the negative. We have seen that, of late years, scarlatina has appeared in the Bombay and Madras Presidencies, having been imported in troopships; but the fact that diphtheria has prevailed in Calcutta for upwards of thirty years, although no unimpeachable case of scarlatina has been observed in Lower Bengal, goes far to show that these two diseases are, to say the least, very separate entities.

The returns of our *British Force*, in all India, for 1880, show two deaths from diphtheria; for 1881, only one death; and for 1882, no death, in a force 57,269 strong. There was not any case of diphtheria among the *women* during the three years; but, among the *children*, numbering from 6,208 to 7,596, there were, in 1880, 18 cases of diphtheria, with 11 deaths, and 40 cases of "croup and laryngitis," with 14 deaths. In 1881, diphtheria did not occur among the children, but there were 388 admissions for croup and laryngitis and 28 deaths. In 1882, no mention is made of diphtheria, but 26 children were treated for croup and laryngitis and 7 died. During the three years, only two admissions for diphtheria occurred in the *Jail population*. In 1880, their average strength was 106,763, and, in that year, one case (fatal) was registered in the Bengal, and one in the Bombay Presidency. There was only one admission (in 1880) for diphtheria in the *Native Army* in the three years. In 1882, this force was 114,894 strong.

In my time diphtheria was rather common in and out of Calcutta, and probably is so still. As I have already mentioned, one of our hospital surgeons fell a victim to the disease, contracted in examining a patient in his ward. I opened the trachea in two cases—in that of the European boy alluded to above, and of a young native man. My colleague, Mr. Partridge, requested that I would (my residence being in the college) watch the latter. He had come in much exhausted, thin rags of dark-coloured exudation matter, like sodden brown paper, hanging from his soft palate. As I stood at the foot of his bed looking at him, foam gathered at the corners of his lips, and in a moment I saw that he died. I did not lose an instant in making the first incision with my penknife, while I called for the scalpels and cannula, which were close at hand. A large tube was inserted, and Sylvesterism was immediately employed, and long maintained, but quite in vain. This case forcibly illustrated the almost instantaneousness with which death from exhaustion occurs in this disease. It was in strong contrast with that of a patient of Sir Joseph Fayrer's, who, having some considerable time previously had his trachea opened, suddenly pulled the cannula out and appeared to die immediately. A nurse ran out of the ward into the operating theatre, and called Sir Joseph, who was operating and could not leave. I went, at his request, put in the tube, and, as a matter of routine, but without any hope of saving the man, I employed Sylvesterism, and was astonished to find that breathing was restored. I published the diphtheria case some time ago, and think that a hint was made soon afterwards, that I had forced the exudation down the trachea and so arrested respiration. This positively did not happen. I examined the case very carefully *post-mortem*. There were mere traces of thin exudation in the air passages, but nothing that could occasion obstruction; and, as we worked the chest, mechanical respiration was perfectly free, air passing through the cannula at every stroke as if through the nozzle of a bellows. This was the only case of diphtheria which I saw in a native.

(To be continued.)

THE FALLACIES OF EMPIRICAL STANDARDS IN WATER ANALYSIS AS TOLD BY THE STORY OF A POLLUTED WELL.[1]

By ALFRED ASHBY, M.B., F.R.C.S.
Medical Officer of Health and Public Analyst, Grantham, &c.

The author had recently analysed some water from a well 35 feet deep, and found in 100,000 parts, chlorine 7, nitric acid 5, sulphuric acid 5·2, phosphoric acid, very heavy traces, total solids 51, free ammonia ·0009, albuminoid ammonia ·0055. If he had judged it by Mr. Wanklyn's standards, it would almost have come under his Class 1, "Waters of extraordinary organic purity;" but it only just entered his Class 2, "Waters safe organically." He neglected those empirical standards, and judging by the ordinary sewage accompaniments in it, pronounced it impure. The owner then had the well examined, when it was found that the lining, of dry laid bricks, and very defective, extended for a depth of seventeen feet through clean gravel, of which he showed a sample, into the variegated red marl of the Trias, which continued to the bottom. Surface water from the gravel trickled in all round the lower part of the lining; near the bottom of the latter was a black patch in the brickwork, and he showed some black gravel he had taken from behind it. Thirty feet off was a recently emptied water-closet cesspool, from which sewage had leaked into the gravel; a privy stood eleven feet from another side of the well, and at the back of it filth had evidently soaked into the gravel seventeen feet from the well. Drains passed at distances of two and six feet from the well. He determined the chlorine in the surface drippings opposite the privy, from the black patch and from the opposite sides of the well, and found in 100,000 parts 8·4, 6·4, 5·8 and 5·4 respectively. On the previous day the black patch drippings contained seven parts of chlorine, which showed that this water was of variable constitution. The gravel water would naturally have the same composition all round the well, so the relative impurity of the drippings might be judged by the chlorine. It was therefore clear that

[1] Abstract of a Paper read before the Society of Medical Officers of Health, April 18th, 1884.

there was most pollution opposite the privy, next at the black patch. Water from the former spot yielded per 100,000 parts, chlorine 8·2, nitric acid 5·7, phosphoric acid, very heavy traces, total solids 56, free ammonia ·0323, albuminoid ammonia ·0282. Water from the black patch yielded, chlorine 6·6, nitric acid 19·4, phosphoric acid, very heavy traces, total solids 72·6, free ammonia ·0018, albuminoid ammonia ·0167. To make certain that the privy had allowed impurities to soak into the well, he had rock salt put into the vault, and had it filled with water. In 28 hours the drippings from the well lining opposite the privy had 11·3 parts of chlorine, an increase of about three parts per 100,000.

The well was then pumped empty, when he descended and took some water as it issued from the red marl about two feet from the bottom, which yielded per 100,000 parts, chlorine 6·1, nitric acid 7·5, phosphoric acid, very heavy traces, total solids 52·4, free ammonia ·0016, albuminoid ammonia ·0079. These results were somewhat inferior to the original analysis, which he considered might be accounted for thus : 50 yards from the side where the bottom sample was taken, was a stable well sunk into the same formation, which analysis showed to be very polluted with soakage from a drain, cesspool, privy and manure heap. The house well having been pumped dry, there was a strong inflow from the marl when some of the impure stable well water would be drawn into it, mixed with the purer intervening water. In order to ascertain, if possible, the natural composition of water from that particular stratum, he analysed some from a well at a house in large grounds 100 yards off, and found per 100,000 parts, chlorine 1·6, nitric acid 4·6, phosphoric acid, very heavy traces, total solids 31·9, free ammonia ·0013, albuminoid ammonia ·0188. This, though not above suspicion as to its purity, might be taken as showing the composition of the best well water that could be got in that part, and it would be seen that, although its organic matter was higher than in the well water under consideration, yet the usual sewage accompaniments in it were less. These analyses and facts had established the assertion that water taken from the well was capable, as occasion arose, of conveying specific infective matter of filth diseases to any person partaking of it, empirical standards notwithstanding.

The author also showed a series of analyses of waters, taken from the same and other geological formations, which did not exhibit a large proportion of organic matter, and which would have come within Mr. Wanklyn's class styled "safe organically," but in which the sewage associates were unusually high. He detailed the source of pollution in respect of each, and stated that in all cases it was very near the wells ; many of the waters had been examined because they had plainly caused the spread of typhoid fever.

In well water, in more recently inhabited parts, oxidation was often less complete, there being less nitrates, but when ground had become saturated with sewage and changed into a nitre bed, as it were, then oxidation was carried much further ; but surely it could not be argued that water which had passed through such sewage-befouled soil was likely to be the less dangerous on that account, notwithstanding that much of the organic nitrogen might appear as nitric acid instead of in its original form. In the series of analyses the average nitric nitrogen was 8·28, whilst the average albuminoid ammonia nitrogen was only ·0075 per 100,000. So 1,100 parts of the original organic nitrogen had been oxidised and only one part was left, showing that residue to be of a different and far more permanent character than the bulk representing, however small it might be, in all likelihood the organised and more resisting living part of the polluting matter, which might be a most potent agent as a disease carrier. So it mattered not how small it appeared in the analytical results. It would seem that greater danger lurked in that more stable organic matter than in the more readily oxidisable part ; greater significance, therefore, must attach to minute quantities of organic matter when accompanied by any excess of the usual sewage accessories, chlorine, nitric, sulphuric, and phosphoric acids, over the normal standards of the natural water yielded by the geological formation from which a sample may have been taken, than when those substances were normal in amount. It was safer to judge a water by the mineral constituents enumerated than by organic indications, readily changeable as they were. The author had found a dried Daphnia pulex to weigh rather less than $\frac{1}{300}$ grain which, on distillation with alkaline permanganate, yielded albuminoid ammonia which would have appeared in a water analysis as ·0005 per 100,000. Each yeast cell had but a weight of one ten millonth of a grain, and he would err on the right side if he assumed that a disease germ weighed as much. It would take 50,000 to equal the Daphnia and to yield the insignificant quantity of albuminoid ammonia mentioned ; and if half a pint of water yielding no more were drunk, about 2,200 yeast cells, and probably many more disease germs might have been swallowed, yet, forsooth, an empirical standard based upon the organic indication would declare the water to be absolutely safe and free from danger ! The author had known arsenic in quantities poisonous to beasts, and carbolic acid to pass through the ground into wells fifty yards away, and he could not doubt that the infinitely small organised bodies could be conveyed at least as far ; and as they probably resisted oxidation far more than putrescible animal matter, being the agents by which those substances were nitrified, much of the accompanying filth would be found in the water as nitric acid, whilst they would furnish organic carbon and nitrogen, or albuminoid ammonia, which might be represented in the third or fourth place of decimals ; yet, surely, since they were the morbific agents, the danger was none the less, even if those figures were small. Mr. Jacob and Dr. Thorne Thorne had proved the infected dejections from a single individual to have spread typhoid fever far and wide through the Caterham water supply. How much greater danger therefore must there be from the continual soakage of even very small quantities of sewage impurities into the limited and confined water in a house well.

Experiments made with the analysis of water containing portions of solid excreta only did not correspond with the circumstances actually met with in practice, for there we had all the other constituents of sewage to help in forming an opinion. If tricks had been played with a sample, surely analysis must not be blamed if correct results were not arrived at. But if we looked at Dr. Dupré's analyses made for Dr. Cory, it would at once be seen that the phosphoric acid, the importance of observing which was first insisted upon by Mr. Hehner, was a sure indicator of the presence of excreted matters, and was more uniformly reliable than the attempted estimation of organic matter. He thought those results showed we ought not to attempt to give any absolute opinion of the relative amounts of pollution in any waters on the data given by attempts to estimate organic matter. Consequently it was unscientific to classify waters on such determinations alone. To judge a water with any approach to infallibility, we must first know all about its derivation. Our only standard must be the natural water of the locality, and of the geological formation from which each sample was drawn, then the least deviation from that would be a sure indication of pollution. Had not the standards which had been proposed led to diametrically opposite opinions

being passed on the same waters by different chemists? What was the result of adopting any empirical standard—did it not increase that discreditable muddle? He contended that it did in an extreme degree, and rendered confusion worse confounded. He argued that any limited standard told us actually nothing about the presence or absence of sewage. With water analysis, it was not a question of quantity in sewage pollution; we could not say that one quantity of pollution was dangerous, but that a half or a third of it was innocuous. The fact was, that if a water exhibited the usual accessories of sewage, however small or large the indication of organic matter might be, it must be considered dangerous and unfit for dietetic use until we became acquainted with the natural conditions by which infective material can be rendered inert and harmless. The method of determining organic matter, whether chemical or biological, whether by the combustion, distillation, or oxygen process, was a matter of little moment. They were all more or less quantitative tests, and told very much the same tale. It was to the wretched wrangling in the past over the rival processes, and to the ridiculously exaggerated importance that had attached to them, was due, in a large degree, the discredit into which water analysis had fallen amongst engineers and sanitarians. The facts the author had given should prevent any analyst from fearlessly pronouncing a confident expression of opinion as to the perfect safety of a water, more than likely of unknown origin. If there were much indication of organic matter, it was often a help in condemning a water, but the absence of it, *per se*, should not induce an analyst to report favourably on a sample He was perfectly convinced that analysis of water might furnish valuable *positive*, but not *negative*, evidence as to pollution.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

WESTMINSTER HOSPITAL.

INTESTINAL OBSTRUCTION DUE TO PERITONITIS FROM PERFORATION OF THE VERMIFORM APPENDIX.

By H. B. DONKIN, M.B., F.R.C.P.

Physician to the Westminster and East London Hospitals.

I RECORD the following case because of:—

1. The sudden onset of the symptoms which led to the diagnosis.
2. The interest attaching to the *post-mortem* examination.

G. C., a boy, aged 13, having been previously in good health, was seized with an attack of sickness and abdominal pain, on the 28th December, 1883, soon after playing football. The pain recurred paroxysmally, and he complained of headache. The bowels acted that evening, and again on the morning of January 1st, 1884. The pain becoming worse, the boy was admitted into the Westminster Hospital on January 2nd. He had vomited but once, viz., at the beginning of the attack, before admission.

The patient, on admission, had an anxious expression, the naso-labial line being well-marked, and he lay on his back with the legs slightly drawn up. An occasional hiccough caused great pain. The abdominal pain appeared to be very severe, coming on in paroxysms every few minutes, and was referred by the boy to the region of the navel. The belly was slightly distended, and tender on pressure all over. The percussion note was tympanitic, except over the right iliac region, where there was an area of much diminished resonance. The breathing was hurried, shallow, and thoracic. The tongue was moist and whitely coated. Pulse 88, small and hard, temperature 99.

No hernia or tumour could be discovered in the abdomen, after a fairly satisfactory palpation, which was not precluded by the tenderness. The heart and lungs were found to present no abnormality to physical examination. The urine was passed with some pain, and in very small quantity—containing no albumen.

On inquiry about the last bowel-action on the previous day it was ascertained from the boy himself, who was very intelligent, that it was very slight: only a few small lumps coming away. Considering all the symptoms and possibilities, a provisional diagnosis was arrived at that the case was one of intestinal obstruction, probably due to a twist or perhaps to intussusception. He was ordered hot fomentations and opium.

On the evening of this day (January 2nd) he vomited some bile-stained sour-smelling material. He however slept fairly well, though frequently awakened by paroxysms of pain. The temperature during the night ranged from 96·8° to 99°, never rising over 100° throughout the case; nor did the pulse ever exceed 102°. Vomiting took place four or five times during the next day (January 3rd); on the last two occasions, towards evening, the vomited matter had a distinct fœcal odour.

In the evening an elastic tube was passed up the gut for about 18 inches, as far as it would easily go. Three quarts, or more, of tepid water were injected. The percussion note became dull over the whole of the abdomen. After a short retention the water was voided, with a few small scybala, and the percussion note was found to be as before—resonant, with the exception of the dull patch on the right side. After a grain of opium the patient had a fairly good night. On the morning of the 4th, the expression was more anxious; skin very dry, belly more distended, and tongue drier. At 8 o'clock there was vomiting, obviously of fœcal matter. At noon, vomiting again, still more fœcal, and three times again before 9 o'clock in the evening. Hardly any urine passed. It had been decided in the morning to explore the abdomen by operation should the patient get worse. The opinion was, that the obstruction was in the small intestine. At 9 P.M., Mr. Macnamara opened the abdomen in the middle line below the umbilicus. A small quantity of pus, with a *distinctly fœcal smell*, flowed away when the peritonæal cavity was opened. The large gut was distended with flatus and congested. A portion of gut was found bound down by adhesion to the posterior part of the left iliac fossa; the adhesion, however, readily giving way to the exploring finger, leading indeed thus to its discovery. Nothing further was found by examination, which however was not complete. It was decided not to turn out the whole length of the intestines for the purpose of examination, especially on consideration of the peritonitis and the fœcal character of the exuded pus, which pointed to perforation having taken place somewhere. The wound was then closed. The patient seemed in no way affected by the operation. About half-an-hour afterwards vomiting set in again, of the same nature as before, and the pain returned in paroxysms, gradually becoming more severe. The next morning January 5th, the pulse was feebler and more rapid; forehead clammy, pain agonising. The boy died a little after mid-day; the temperature rising to 100° before death, and to 102·5° a few minutes after.

The *post-mortem* examination was made 26 hours after death. (1.) Acute general peritonitis was found,

most intense at lower part of abdomen ; the intestinal coils were matted together, their surface being covered with thick yellow lymph. The upper part of the gut was distended, while the lower part was flaccid and contracted, though it contained several small scybala. 2.) The vermiform appendix was found to be perforated by what was apparently a calculus ulcerating its way through its wall. This object was $\frac{7}{10}$-inch long and $\frac{1}{4}$-inch broad. It consisted of fœcal concretion. (3.) On exploring the small intestine an obstruction was found five feet six inches above the cœcal valve, consisting of two coils of gut closely matted together. At the point of kinking the gut was found to be very narrow, measuring only one inch in circumference, this constriction appearing, on close examination, to be in no way caused by disease, but congenital. A little below this the gut resumed its normal size, just above it measured four inches in circumference, and higher up was much distended. Below the constriction the mucous membrane was bright red—above it was pale. A large quantity of thin fluid fœcal matter occupied the gut above the constriction, and also the stomach, but with the exception of considerable pulmonary congestion, nothing else abnormal was revealed by the *post-mortem* examination.

The diagnosis of probable intestinal obstruction was made in this case before the fact of the non-passage of fœces was made out, mainly on the ground of the suddenness of the onset of the pain, &c., its paroxysmal character, the absence of fever and of any other morbid sign or symptom. By further observation this diagnosis was made almost certain, and it became probable that the obstruction was not low down.

The sequence of events was probably as follows :—

1. The perforation of the vermiform appendix by the concretion found half way out of it.
2. Peritonitis, and a tendency to matting together of the intestines.
3. A kink and tight strangulation by the effused lymph of the congenitally narrowed portion of the jejunum above described.

It is of course impossible to say at what period after the beginning of the peritonitis the obstruction occurred, but judging from the pain very soon assuming a paroxysmal character, it was probably early. The stercoraceous vomiting, though occasionally taking place in peritonitis without mechanical obstruction, was here very distinct and profuse, and considering that the symptoms of general peritonitis were not very marked till the close, and the temperature was scarcely above normal, this was a valuable sign of obstruction.

The peritonitis caused by the perforation of the frequently peccant vermiform appendix would alone have caused death in this case ; the second natural malformation, viz., the narrow part of the gut, being, however, an ever present source of danger, and contributing its own special symptoms.

The boy stated, when he first came to the hospital, that he had a blow in the stomach when playing at football, which hurt him very much : possibly this may have expedited the progress of the calculus through the wall of the appendix.

Dilating the Os Uteri during Labour.—From a conversation upon this subject that took place at the Obstetrical Society of Philadelphia (*Philadelphia Medical News*, April 12th), it would seem to be the general opinion that the precept usually given of abstaining from the dilatation of the os is not approved of by several members of the society, who have found the practice of careful dilatation to hasten slow labours, and to be unattended with bad effects, and especially when the waters have been prematurely discharged. According to some, even an irritable os is thus subdued, and when its rim is wiry and thin, or hard and thick, it softens and yields.

Medical Times and Gazette.

SATURDAY, MAY 10, 1884.

The imperfections, real and alleged, of the Lunacy Laws formed the subject of a discussion in the House of Lords on the 5th instant. Lord Milltown called attention to observations made by Mr. Baron Huddleston in the case of "Weldon *v.* Winslow ;" and moved, "That in the opinion of this House the existing state of the Lunacy Laws is eminently unsatisfactory, and constitutes a serious danger to the liberty of the subject." In support of the motion, Lord Milltown, in addition to copious quotations from the judgment given by Mr. Justice Manisty on the application of Mrs. Weldon for a new trial in her case, as well as from Mr. Baron Huddleston's charge, drew largely on his own imagination and fears. He informed his noble brethren that a constable or a relieving officer may arrest any one found wandering abroad, and bring him before the Justices of the Peace, and on the certificate of one medical man and the warrant of the Justices, such a person might be incarcerated for life ; and "thus," he added "any one of your Lordships might be confined for life as a pauper lunatic." In like manner and degree the noble lord magnified all the weak points in our Lunacy Laws, and exaggerated the dangers that may possible arise from such imperfections, while he ignored or minimised the value of the safeguards that those laws provide. He concluded with an attack on the system of private lunatic asylums, which he considers a most damning blot on the Statute Book, and which, he declared, the Earl of Shaftesbury had, some years ago, described as utterly abominable and indefensible.

Lord Shaftesbury, who followed Lord Milltown, did not refer to the subject of private lunatic asylums, but contented himself with pointing out the reality and value of the safeguards contemned and condemned by Lord Milltown, and spoke, at considerable length, of the immense improvements that have been made in the management and treatment of the insane during the last sixty or seventy years. It was natural that his lordship, who has for more than fifty of his eighty-three years of life been connected with the Lunacy Commission, should feel that the present abuses of the Lunacy Laws are absolutely trivial compared with those he has himself seen and done so much to remedy. He did not, however, affect to suppose that the present laws are even humanly perfect. Lord Coleridge insisted that, though all the improvement noted by Lord Shaftesbury has happily been achieved, much yet remains to be done. In the great majority of cases of alleged insanity, it is absolutely clear, he said, to the intelligence of any ordinary person moderately acquainted with the matter, that the individuals confined are sane ; and in another large class of cases it has been equally true that the persons whom it was proposed to confine were not insane. But on the dividing line between these classes the system of the

Lunacy Laws, though excellent on paper, broke down. It is always on the dividing line between conditions that a system, always most strained, must at times break down. Lord Coleridge told us nothing new in his criticism of the law, and suggested no means for making it less liable to break down.

The Lord Chancellor reminded the House of the need of looking at the statements made, and at the subject before them, in a sober-minded practical way. They must remember that the Lunacy Laws are made for lunatics; and that, while lunatics have to be protected against themselves, and to be treated with a view to cure, the sane public have to be protected from the insane. In these conditions very wise and well-framed laws are needed to secure the safety and well-being of the lunatic without infringing on the liberty of the sane. He thought it was worth while to consider whether it was possible to amend the present law so as to diminish the possibility of abuse in the administration of it, without the danger of interfering too much with its proper administration; and he undertook, on the part of the Government, that should they retain the confidence of the country, they would in another session bring forward a Bill to consolidate the existing laws with improvements recommended by the Committee of 1878, and others that may seem advisable.

Lord Salisbury said that a reform of the Lunacy Laws was much needed, though he recognised the great difficulty of dealing with the subject satisfactorily. His tone was, however, like Lord Milltown's, much exaggerated; and, like Lord Coleridge and Lord Milltown, he also denounced private lunatic asylums. None of these critics appear to remember that such asylums are a natural outcome of our English system of providing as much as possible for our needs by private enterprise, instead of trusting to the State to help. The end of the debate was, that Lord Milltown, in view of the promise made by the Lord Chancellor, withdrew his motion.

When the House of Commons went into Committee of Supply on Monday last, it spent some hours over the Army Estimates, and a considerable portion of that time was devoted to a discussion on the vote of 303,000*l.* for medical establishments and services. Mr. Dawnay used the vote as an opportunity for delivering himself of an attack on the working of the Medical Department in the Egyptian campaign. He appreciated, and was "satisfied with" the unflagging energy shown by the medical officers of regiments in the discharge of their duties at Tel-el-Kebir, and at the front generally; but that "could not make him tolerate or pass over that departmental apathy and want of organising power which were forced upon him" by the want of arrangements for the care of the sick at Cairo and Ismailia. He appears to accept all the extraordinary evidence given by Lord Wolseley, and other hostile witnesses, before Lord Morley's Committee; and considers that the alleged "shortcomings" of the Army Medical Department, and "breakdown" of the Army Hospital Service, were indisputably and fully proved.

All this is however an old story, and the accusation, brought against the medical officers, and the question of the alleged failure of the Medical Department were fully thrashed out and disproved in our columns, from the evidence before Lord Morley's Committee, when the Blue Book containing the proceedings of that Committee was published. It was easy, therefore, for Dr. Farquharson and Dr. Lyons to fully vindicate the efficiency of the Medical Department; but it is very gratifying to note that both Colonel Stanley, who was Secretary of State for War during Lord Beaconsfield's Government, and the present Secretary of State, the Marquis of Hartington, admitted that "the charge of inefficiency and want of care brought against the medical officers had been entirely dropped, and they had come out of the inquiry, so to speak, with flying colours;" and that "it was conclusively proved by the investigation by Lord Morley's Committee that there was nothing which could be called a breakdown in the medical arrangements in Egypt." Lord Hartington admitted, of course, that "there had been a certain amount of inconvenience, a certain amount of hardship, and a certain amount of want of preparation at particular stages of the campaign;" but he said, as he has said before, and as we have all along contended, that it has been conclusively proved that such inconveniences and such failures as did occur were owing, not to any lack of duty or management on the part of the Medical Department, but either to the conditions of the campaign, or to the fact that there was a necessarily sudden military movement which made it impossible for the Department to be always so fully and efficiently ready as the medical officers desired, to perform all the duties which fell upon them.

It scarcely need be added that it was not denied that there was a failure in "the thorough organisation of the departments of supply to the Army." It is admitted on all hands that the organisation of the Army Hospital Corps was, and is, very faulty; that the nursing was bad, and the cooking was bad. But a Committee to enquire into these matters is now sitting; and some improvements, recommended by Lord Morley's Committee, have been accepted by the Government. It has been determined to amalgamate the Army Hospital Corps with the Medical Department, and to provide efficiently for the full training of the men of the corps; and Dr. Farquharson rightly congratulated the Secretary of State for War upon the abolition of the useless, worse than useless he might have said, post of Military Commandant at Netley. We join with him in hoping that the grievance complained of in that respect will not be perpetuated in another form; that the officer appointed to perform some of the duties of the former commandant will be subordinate to the principal medical officer; and that the latter will have no superior officer except the officer commanding the district.

Mr. Dawnay's real object, however, in framing his indictment against the Army Medical Department was to arraign the unification system of appointing the medical officers, or, as it is more generally called

the departmental system, and to urge the absolute necessity of returning to a modified form of the regimental system. Much of the debate dealt with this matter, and not profitably; it is by far too large and important a subject to be discussed on a vote in Supply. Colonel Stanley holds that a compromise between the departmental system and the regimental could not fail to produce good results, and he has never been able to see any difficulty in arranging it; while Lord Hartington is of opinion that the results of the present system are most satisfactory; that it would be unwise, and certainly very difficult, to introduce changes which "are altogether opposed to the feelings of the medical profession," and were rejected by a very large majority of Lord Morley's Committee. The truth really lies between the two opinions; and probably it would not be difficult to arrange a good working compromise between the systems in question, each of which it is admitted has real and grave faults, if the Government were not so determined not to spend one shilling more than they can be forced to spend on the Army Medical Department. No Ministry has as yet had the courage to endeavour to educate the House of Commons to anything like a fair comprehension of the importance of the relation which the full and effective organisation of the Medical Department bears to the efficiency of an army. It must be admitted that the Secretary for War was somewhat vague in his statements with regard to the proposed large general army hospital to be established in London. It cannot be entertained, he said, until the question of regimental hospitals has been thoroughly disposed of; but that cannot be disposed of "for some time to come;" and the medical arrangements for the Guards cannot be assimilated to those of the rest of the army till a general army hospital has been established in London. The meaning of it all is, however, that the regimental system of medical officers will still be permitted in the Household Troops.

THE *Conversazione* at the Medical Society, on Monday last, with which the present session was brought to a close, was very successful. The whole suite of rooms was thrown open, but although a large number of fellows were present, there was at no time of the evening any of that overpacking, which is the bane of so many gatherings of this kind. Mr. Durham, the President, aided by the energetic and courteous secretaries, Dr. Fowler and Mr. Gould, did the honours of the evening in a very pleasing manner. The rooms looked exceedingly well, the walls being decorated with etchings and autotypes. There was the usual display of microscopic varieties, chiefly of the bacterial type, and of new instruments, including some excellent electrical apparatus both for lighting and therapeutic purposes. Dr. Theodore Williams delivered the annual oration. He dealt chiefly with the social aspects of the medical profession, and pointed out in what manner its status and general usefulness might be promoted. The Medical Society shows a vitality and freshness which the sister societies might not unprofitably imitate; such gatherings as that we now chronicle cannot fail to interest its fellows, and add strength and cohesion to the Society at large.

THE list of communications on Tuesday last at the meeting of the Pathological Society was longer than ever, but it was nevertheless given a good account of, mainly by dint of having next to no discussion on any of the specimens, and referring those about which there seemed to be any doubt to the Morbid Growths Committee. We do not wish to imply that the officers suppressed discussion, but there was no very manifest tendency on their part to stimulate it. The revival of the practice of showing specimens by card is one that we greatly rejoice to see; many pathological curiosities can thus be shown and recorded without occupying time that might be better employed in discussing difficult or doubtful points. The number of card specimens was greater than on any previous occasion since this very useful innovation was started some four years ago.

MR. SYDNEY JONES showed a magnificent series of bones from a case of multiple exostoses. It is difficult to believe that any finer collection exists. Mr. Knowsley Thornton showed the spleen which he had removed by abdominal section from a young woman, as mentioned in our last number. The patient appears to be making a speedy recovery, a result which we have hardly learnt to look for from the hitherto recorded cases of this operation. Of the papers, that of Dr. Samuel West on tumours of the lung was the most important. He traced very clearly the growth of the so-called primary tumours from the lymphatic structures at the root of the lung, and pointed out how they invaded the lung by following the course of the bronchi. His paper constitutes a valuable contribution to our knowledge on this subject. Mr. Treves' case, too, deserves mention, as illustrating the difficulties that may be met with in the diagnosis of sarcomatous or other growths when they apparently assume the characters of an infective disease.

THE ordinary meeting of the Obstetrical Society was held on Wednesday evening last, May 7th. Three papers were read. The first was by Dr. Arthur Mitchell, on the effect of strong mental emotion in the mother in producing idiocy in the child. The author said that he had convinced himself of the occasional causation of idiocy in this way, supported this opinion by cautious *à priori* reasoning, and quoted some cases in illustration. But he admitted that the evidence he could adduce was not demonstrative. The paper, therefore, although it would influence greatly the opinion of those who knew the soundness of Dr. Mitchell's judgment, yet could not be said to throw fresh light on the subject. Dr. Charles West, and Dr. Fletcher Beach were among those who took part in the discussion. Then followed a remarkable case of extra-uterine fœtation, successfully treated by extraction of the fœtus per vaginam, and separation and removal of the placenta, communicated by Dr. Mathieson, a Canadian physician. So unusual a case called forth some criticism. Lastly, a short paper by the President, on a unique case of cystic degeneration of the cervix uteri, the cyst containing gas. The President, at the beginning of the meeting, called the attention of the Society to the large number of papers waiting to be

read, and the consequent necessity for brevity in the description of specimens and discussion thereon. This Society, we think, would do well to follow the example of the Pathological, in economizing time by permitting specimens to be shown by card.

The Quarterly Meeting of the Medico-Psychological Association was held at Bethlem Hospital, on Tuesday, May 6th, Dr. Orange, President, in the chair. A letter was read from Dr. Manley, the President-elect for the ensuing year, announcing his inability, through ill health, to fulfil the office to which he was elected at the last Annual Meeting. A resolution of regret and condolence at this having been duly passed, the President stated that, acting under the Association's Rule providing for such emergency, the Council had exercised the duty imposed upon them by electing Dr. Rayner to act as President during the coming year. Papers were read by Dr. Hayes Newington, on "Unverified Prognosis," and by Dr. Bonville Fox on "Exaltation in Chronic Alcoholism," and Dr. Mercier introduced resolutions in favour of the Transference of Lunatics of Foreign Nationality to their own countries.

Samuel Gross, "the Nestor of American Surgery," as he has been called, is dead. He was born in 1805, took his M.D. degree and commenced practice in Philadelphia, in 1828. His first work on "Diseases and Injuries of the Bones and Joints" was published two years later. From that time until 1881, when he gave to the world his last publication, "John Hunter and his Pupils," his literary activity was immense. His well known "System of Surgery" first appeared in 1859, and has since passed through several editions. He was also for many years engaged in different posts as a medical lecturer, and in 1856 was appointed to the important one of Professor of Surgery in the Jefferson Medical College, Philadelphia. Dr. Gross only retired from the active practice of his profession about eighteen months ago.

It is with great regret that we observe in the *Athenæum* a notice of the death, at the early age of 49, of the enterprising bibliographical publisher, Frederick Leypoldt. The leading spirit in devising and conducting several of those valuable aids to the literary and publishing world, of which the United States may so justly be proud, our view of his efforts is chiefly derived from a knowledge of the great services that he rendered to medical literature by carrying on the *Index Medicus* at a great expenditure of money, time, and exertion, and that amidst a most discouraging absence of appreciation, or at all events of pecuniary aid. Those who have had opportunities of judging of these efforts in sustaining so valuable a publication, can only speak of them with admiration and gratitude, and express a not very sanguine hope that their withdrawal may not be followed by the cessation of this useful compilation.

We have been requested to call attention to the fact that the competition for the Alexander Memorial Prize and Gold Medal is still open, and that essays may be sent in as late as the last day of the present year. The competition is limited to Executive Medical Officers of the Army on full pay, and the subject is one which must deeply interest the Department, viz.: "Antiseptic Surgery and its application in Military Hospitals and in the Field."

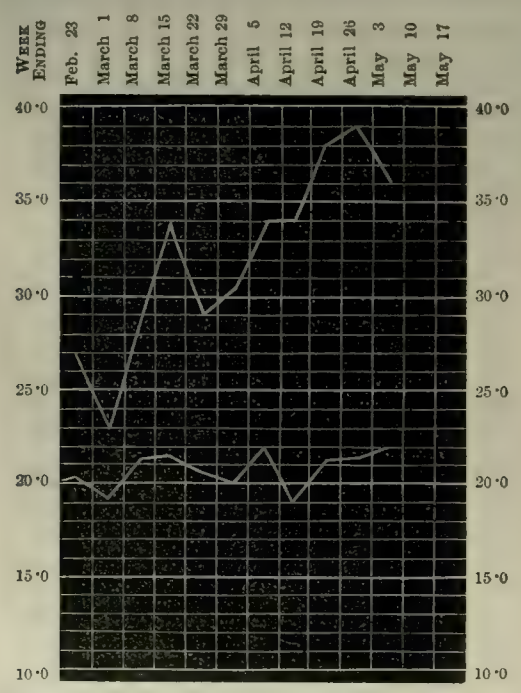
Amongst the newly-elected Fellows of the Royal Society, the medical profession will note with pleasure the names of Professor M'Kendrick, Professor I. B. Balfour, Dr. C. S. Roy, and Dr. A. Ransome, of Manchester.

Dr. Cameron's unsuccessful attempt to secure State regulation for cremation has met, on the whole, with sympathy from the lay press. The *Times*, with that cynical bias against "sentiment" which usually leads it so far astray in its opinions on medico-legal problems, while expressing itself strongly in favour of Dr. Cameron's proposal, attempts, most unfortunately, to minimize the single valid argument against it, viz., the increased difficulty that cremation would put in the way of detecting cases of poisoning. This is an argument which science will have to meet, and doubtless will meet, if cremation is to become common. It is not an argument to be pushed aside with the totally inapplicable aphorism, *de minimis non curat lex*. The *Standard*, on the other hand, always well informed and reasonable on medical subjects, gives full weight not only to the poison-detection difficulty, but also to the "sentimental obstacles." It thinks that the promoters of the Bill ought to have converted the public to their views before endeavouring to convert Parliament. The *Morning Post* also thinks that the "sentimental objections to cremation are very powerful, not to mention those based on the facilities which might thereby be afforded to the poisoner." Nevertheless, it frankly confesses that if no stronger arguments can be found against it than were supplied in the speeches of Sir William Harcourt and Sir Richard Cross, a crematorium will at no distant day be added to our national institutions. The *Daily Telegraph* differs from the *Standard* in thinking that popular opinion has already undergone a change in regard to cremation, but it holds that "the feelings which circle round the disposal of the dead are very deep and tender, and that it would be folly to attempt legislation tending to shock or outrage these tender sentiments." As to the poison difficulty, it is sure that "some device can be invented to checkmate the vile purposes of the secret poisoner." The *Daily News* also admits that this difficulty must be surmounted if the Bill is to pass, and holds that "prejudice against cremation must be treated tenderly, however unreasonable it may seem." Taken together, these utterances show that the press is becoming educated, even if the public is not. Five years ago the dailies would have treated this question in very different style.

Many years since, if our memory be not playing tricks with us, we read a fairy tale in which a little boy besought his fairy godmother that he might never again feel pain. His prayer was granted, with results which were to be calculated upon by any one of

ordinary intelligence, and which pointed the obvious moral that even pain has its uses. The same idea has been lighted upon by Dr. Milner Fothergill, and refurbished with all his well-known gift of physiological and pathological illustration, into an elaborate article in the current number of the *Contemporary Review*—almost the only paper of medical interest in this month's magazines. The article is grandiosely entitled "The Logic of Pain," and has one conspicuous merit, brevity.

The number of deaths registered in London last week, viz.: 1,697, was higher than that recorded in any previous week of the present year, and exceeded the ten years' average by 82. The zymotic deaths, however, showed a decline, though they were still 47 above the average, and the rate, as may be seen in the chart, still remains unpleasantly high. The smallpox



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of last quarter, and the first five weeks of the present quarter.

epidemic continues to spread, and on Saturday last, five hundred patients were in hospital, but the weekly tale of deaths amounted to only ten. The fatal cases of scarlet fever were slightly in excess of the average, those of enteric fever slightly below it. Measles and whooping cough still continued their excessive demands on infant life, causing between them close on 200 deaths, or 75 more than is usually the case at this period of the year. The most remarkable feature of the week was that no case of suicide was registered, the usual number, as deduced from ten years' experience, being seven all but a decimal point.

In his report for the second half of 1883, Dr. Collingridge is able to show that he and his subordinate officers, representing the sanitary authority for the Port of London, have not been idle. Under the head of unsound meat, the report shows that there has been no lack of activity on the part of the inspectors; in one instance 3,388 carcases of sheep were condemned, and in another 327, whilst thousands of tins of tinned meats were condemned and destroyed during the half year. There do not appear to have been many cases of infectious disease, but whenever such were reported steps were at once taken for the disinfection of the ship, or if she had sailed elsewhere, the medical officer of health at her destination was communicated with. The total number of vessels examined was 14,043, of which only 5·1 per cent. required cleansing. The results of a census taken to ascertain the floating population of the Thames, give the number as varying between 22,000 and 23,000, the average number of vessels being from 2,500 to 3,000. Observations on the temperature of the Thames have also been resumed, from which we gather that although the temperature varies far less at Gravesend than it does at Greenwich, still it is almost invariably higher.

It augurs a satisfactory state of affairs, when a medical officer of health remarks that "there has been so little sickness during 1883, that there is very little to comment upon." The fortunate official in the present instance is Dr. John Shea, and the remark occurs in his annual report on the Wokingham Urban Sanitary District. Dr. Shea is also in charge of the adjoining rural district, and he is able to show that while in the former the death-rate during the year 1883 was 18·7 per 1,000, in the latter it was only 14·9; singularly enough, however, the zymotic rate was the same in each of them, viz., 1·8 per 1,000. During the past year, it has to be noticed, Wokingham has completed its sewage scheme, and the Thames Conservators have accordingly withdrawn their summons against the Local Board for polluting the Emm Brook.

We hear from Glasgow that it has now been definitely arranged by the representatives of the governing bodies giving technical and scientific teaching in that city, to devote the whole of the buildings of Anderson's College to the purposes of the new Technical College, and to give 5,000*l.* to the medical faculty towards the building of a new medical school in the vicinity of the Western Infirmary. The money will be held by Trustees, who will be the governing body of Anderson's Medical School. It is estimated that a suitable building and equipment will cost from 10,000*l.* to 15,000*l.*, and although the amount offered is inadequate, yet it is expected that the Trustees and the friends of the College will make an effort to raise the rest of the sum required, so as to render the new Medical School worthy of Glasgow. When thus equipped, Anderson's Medical School will enter upon a new phase of existence, and be able to act as a healthy stimulus to the University, and maintain the honours of its past history.

In reply to a very complex question, put on Monday in the House of Commons, the President of the Local Government Board said that the Board had no know-

ledge, except from the public press, of the medical report that the reopening of the Homerton Hospital for small-pox patients had caused a spread of the disease in its neighbourhood; but he understood that the Board of Managers intended to inquire into the matter. He knew that they were doing all they could to prevent any possible risk of the spread of the disease from the hospital, not merely by largely reducing the number of patients admitted, but also by clearing adjacent properties, which had been purchased for the purpose of securing a free space round the hospital. With regard to the Diseases Prevention Act of last session, Clause 2 was not intended to deprive the public of any legal protection they possessed against asylum managers or any other local authority carrying on a hospital in such a way as to cause the spread of disease, and the Local Government Board do not consider that the clause has that effect. The Act has, as yet, never been put into operation in consequence of an epidemic of either fever or small-pox; and the Board have never contemplated its being put in force except in the case of an outbreak of cholera. The Board, moreover, are fully satisfied that the managers of the Asylums Board desire to take all due precautions to prevent the spread of disease from any of their hospitals.

With regard to this question, a correspondent, who says that he has had opportunities of carefully inspecting the hospital, writes: "It is true that the board have complied with certain of Dr. Tripe's recommendations, but they have not done all in their power to minimise the dangers inseparable from the position of the hospital. The laundry, for example, almost abuts on the boundary wall, which is of insufficient height, being much lower than the roof of the washhouse, from which the steam escapes, and not 60 feet from a row of small houses; the foul linen is allowed to lie outside the building for some hours before being put into carbolic water (for which I would suggest the substitution of chloride of zinc). The position of the drain ventilators beneath the windows of the wards, is open to criticism, and other defects are noticeable. But above all, there can be no doubt that only one block, Pavilion No. 1, is really suitable for the treatment of small-pox cases. During twelve months when it alone was used for this purpose, not a single case occurred in the adjoining streets, and it appeared to me, that if the board really felt themselves compelled to provide accommodation for more cases than could be received into this particular block, a temporary building might be erected in the open space between it and the iron railing which divides the grounds, where it would be even more remote from the nearest houses. The whole history of small-pox infection has yet to be written; for, making every allowance for errors in construction and administration of hospitals, experience has proved, beyond the possibility of doubt, that the contagion of small-pox is capable of being carried by the air for far greater distances than those of fevers; and that while fever hospitals, where the most ordinary case is taken, have never been shown to be a source of danger to the surrounding population, small-pox hospitals, unless under exceptionally favourable circumstances, are always such, to a greater or less extent. Since, however, the retention of small-pox cases in their own confined, overcrowded, and furnished homes, is a still greater danger, as involving the maintenance of innumerable *foci* of contagion, it behoves sanitary authorities everywhere to avoid giving any occasion of provoking or intensifying the prejudice, by no means unfounded, entertained by the public against hospitals for infectious diseases, and shown by the opposition, which ever since the case of Pearson Hill *v.* the Asylums Board, has been presented to every attempt at opening such in the metropolitan area."

The example of the medical officers of English schools has been quickly followed across the Channel, and the *Union Médicale* is able to announce with much satisfaction that a society has been formed by the Medical Inspectors of Schools in Paris. According to the rules of the Society, its objects are principally the due examination of the numerous and too little explored questions relating to the hygiene of schools, and the defence of professional interests, so that a field of great extent is open to the investigations of the new Society. The *Union* believes that it may do much for infantile hygiene, and for the amelioration of school buildings and surroundings, which are at present in a very defective condition in Paris. It will also have performed a very meritorious work if it succeeds in inducing the municipality to listen with more attention than hitherto to the counsels of its medical officers.

One of the most important and best-paid sanitary appointments in the world—that of Officer of Health to the city of Calcutta, with a salary of over 1,000*l.* a year—is vacant, and we have reason to believe that any Englishman who has had long experience of city sanitary work in this country, and can command good testimonials as to scientific ability, will have a very fair chance of being elected. The Municipal Commissioners of Calcutta, who are the electors, met, on April 10th, with a view to filling up the vacancy caused by the retirement of Dr. McLeod, and their choice very nearly fell on a Dr. Von Horck, who is at present in India on a mission from the German Government, but who had expressed his willingness to delay his return for a few years, if elected. Fortunately wiser counsels prevailed, and in the end the meeting was adjourned for three months, with the understanding that further applications would be received. The report of the meeting, including a most able speech by Mr. Jones, the commissioner, to whose influence the postponement of the election was mainly due, is to be found in *The Englishman* for April 11th. We hope that some of our skilled sanitarians may be found enterprising enough to offer themselves for the appointment. The future health officer will have a splendid field for work. In spite of all the efforts of the last fifteen years, the sanitary state of Calcutta is still most unsatisfactory, and there are problems connected with its drainage and water supply which are crying out for solution. An able and conscientious health officer would probably soon see his work telling palpably on the death-rate—that sensitive barometer which accurately registers the amount of sanitary pressure.

The *Allgemeine Wiener Medicinische Zeitung*, of March 11th, contains the following advertisement in prominent type—"A young unmarried doctor of medicine, of the Jewish persuasion, has the opportunity, by marriage, and the succession to a lucrative dental practice, of insuring a very agreeable existence. The practice can be proved to be worth 10,000 florins per annum. The young lady in question is the daughter of highly respectable parents, seventeen years of age, handsome, well brought up, and equally well educated. Her father is desirous of retiring from the business, and will make over to a young doctor of medicine, without compensation, his dental practice, and his excellent dwelling house, with all the material, dental instruments and apparatus of the value of from 8,000 to 10,000 florins. A knowledge of the dental art is not at first requisite, as, under the tutelage of the present professor, this can be acquired in a few months." Applicants are referred for further information to the Editor of the Journal.

Most of us, through the medium of Uncle Remus, have probably become familiar with the terrapin as a genial though somewhat wily animal, but there are other species of terrapins which are not so pleasant to read about. In the Medical Reports published by the Inspector-General of Customs in China, Dr. J. Macgowan, in his report on the health of Wenchow, gives an interesting and amusing account of some of the poisonous animals of that part of the world, and of the superstitions connected therewith. It appears that there are many varieties of terrapin, such as the three-footed, the red-footed, the single-eyed, the non-retractable head and foot, the sunken-eyed, and others which are not to be eaten. The edible kinds are, however, subject to certain conditions; thus, they may not be eaten with spinach or with hen's eggs, ducks or rabbits. Pregnant women partaking of them will bring forth short-necked children, and consumptive persons troubled with abdominal swellings should not use them for food.

The three and the four toed terrapins may be eaten, but the five-toed, which are transformed snakes, and the six-toed, which are transformed scorpions, are fatal poisons. But for thoroughly business-like habits, they none of them can compare with the three-legged terrapin, to which, if the following tale be true, we must henceforth accord a place in the front rank of the most deadly poisons. After being told that it is very cold in its nature, we read: "A man of T'aitsang ordered his wife to cook a three-legged terrapin, which he ate and went to bed. Soon after he was changed to blood and water, his hair alone remaining. Neighbours, suspecting foul play, informed the magistrate, who could make nothing of the case, but ordered a prisoner, who was condemned to death, to eat one of those tripedal chelonians. The consequence was, that nothing was left of the miserable culprit but bloody water and hair, whereupon the widow was acquitted."

It has been very gratifying to us—and all the more gratifying because so little expected—to find Professor Gairdner taking up the question of the position and payment of the medical profession in Glasgow, to which we called attention a fortnight ago. In another column we publish some remarks which he made at the last meeting of the Glasgow Medico-Chirurgical Society, with reference to our notes on the subject. We are glad to hear from the lips of such an authority that there has been a marked and progressive improvement in the remuneration of medical services during recent years, but according to our information the scale of payment of all grades of the profession is, with a few notable exceptions, considerably inferior to that which rules in other opulent centres; and we would again seriously impress this fact on both the profession and the public in Glasgow, that, human nature being what it is, low fees are apt to mean inefficient work. Doctors, like other men, do their best work when they feel that they are earning their salt. That, as Dogbriar says in the play, is "morality and philosophy."

THE APPEAL OF THE APOTHECARIES.

On Tuesday some four-score licentiates of the Worshipful Society of Apothecaries assembled in the Hall at Blackfriars to protest and take measures for petitioning against the clause of the Medical Bill which excludes the Society from representation on the proposed Medical Board for England. The meeting was hearty in its sympathy with the Company, and practically unanimous in approving the petition which it is intended to present to the House of Commons. It also cordially adopted the proposal to appoint a committee to interview the Minister in charge of the Bill, and there was no very great difference of opinion as to who should form the committee. So far, then, the executive of the Company may be fairly congratulated on the success of their attempt to bring pressure to bear upon the Legislature, but it remains to be seen to what extent their endeavours will be supported by the general body of licentiates. Tuesday's meeting was not attended by more than one per cent. of the ten thousand licentiates said to be in existence, and the Government would be justified in attaching very little weight to the opinion of such a gathering. But before many days are over the petition will doubtless be in the hands of every licentiate who is to be got at, and if anything like a fair proportion of possible signatures is obtained, the petition will probably have a definite influence on the decision of the Government. This being the case, we beg those licentiates who may read these lines to weigh very thoughtfully the effect of their action in the matter, and anxiously to ask themselves the question, whether it is expedient and in the best interests of the whole profession, present and to come, that the prayer of the petition should be granted. We are as much interested as any of them can be in the venerable character of the Apothecaries' Company, we are quite as willing as they to admit the good work that it has done in the past, and we have a better practical acquaintance than most of them, both with the examinations at Blackfriars, and the internal management of the Company. And looking at the question from all points

of view, except that of a vested interest, we have come to the fixed belief that the Government have been quite right to exclude the Company from a share in the direction of medical education, that it is the one point in the Bill in which they have shown strength, and that to make them waver on this point, would immensely increase the difficulties, already sufficiently numerous, in the way of speedy legislation.

We will give our reasons for this belief. In the first place we would ask, can the Apothecaries Society show any claim to a voice in the direction of medical education and examination in the future? Yes, exclaims the Society, we represent ten thousand licentiates, nearly half the names on the Register. Pray, how does it represent them? Does it allow them any voice in the election of its executive? Does it ever take their opinion on any point? Certainly not. It is difficult to say exactly how the handful of aged apothecaries who govern the Society are chosen. But assureely, neither the thousands of licentiates nor the hundreds of members have any voice in their election. So far as representation is concerned, the Court of Assistants of the Society is the closest corporation in existence. They represent no one but themselves, and until they saw their existence as an examining body threatened, they consulted no one but themselves. We fail altogether to see how any reasonable man can support their claim to direct medical education on the score that they represent ten thousand licentiates. O, but they will reply, we have great experience in the matter, we have been examining medical students week after week for years. Well, experience in examining is not quite the same thing as experience in educating, and, until lately, anyone with systematic experience of the latter, was practically excluded from the Court of Examiners. But let that pass. The Board, we admit, contains a few able men, and might possibly have a fair claim to a representative on the Medical Board, if it continued to examine. The representative, however, would not be elected by the examiners, but by the Court of Assistants, a very different thing, and the moment the Bill passes, the sole argument for the right of even the examiners to representation will cease to exist, for they will no longer have the opportunity of acquiring experience of examination, at any rate in pass subjects. So that this is practically what the licentiates are asked to petition for, viz.: that a score of old general practitioners, chosen by seniority from a close body of self-elected members, with no special knowledge, or opportunity of gaining knowledge, of the ever advancing conditions of medical education and examination, shall have the privilege of seating a member in perpetuity on the board which is to direct the medical study of the future. Can any licentiate, with a proper respect for himself and his profession, put his name to a petition in support of an anomaly such as that? It will no doubt be suggested to the licentiates in general, as it was to those present at Tuesday's meeting, that the authorities of the Society may fairly claim a voice in medical education, on the score that they have special knowledge of what is required by the public of the general practitioner. But the representation of that special knowledge is amply provided for by the Medical Bill, which places the representatives of the general practitioners, not on the Medical Boards, but on the body which is to control them—the Medical Council. Besides, what guarantee have the licentiates that the Executive of the Apothecaries Society have this special knowledge? None whatever. If the Court of Assistants, who govern affairs at Blackfriars, had come generously before the licentiates and said, "We will at once take such steps as will in the future place our election in your hands," one might perhaps, with a clear conscience, have advised the licentiates to sign the petition, for there would then have been some reasonableness in its appeal; but in the absence of any such sign of a desire to reform itself we can only again express the hope that the licentiates will not support the Society in its ill-advised attempt to imperil the passing of the Medical Bill.

THE DEBATE ON THE ARMY MEDICAL DEPARTMENT.

It was to be expected that the discussion which followed the proposed vote for the Army Medical Establishment for 1885, would turn upon the Report of Lord Morley's Committee, and their recommendations for the improvement of the Medical Department in the future. Our readers will remember that some great questions were raised in this report. There was the power of direct purchase, for instance. The *great* complaint against the doctors was, that when "Transport" failed, when "the Commissariat" could not furnish supplies, and the combatants could give no assistance; the "Medicos" declined to assume a power which by regulations they were *forbidden* to exercise; and refused to purchase recklessly and indiscriminately whatever was or was not wanted. This was really Lord Wolseley's point in his attack on the Army Medical Department. We never expected that this complaint would be alluded to in Parliament. It is too dangerous, too delicate, to handle. When men's minds are excited by tales of battles and distress, it is all very well to cry with Lord Wolseley, that it matters nothing to England whether a loaf for a sick or wounded soldier costs a penny or a guinea! But when the battle story grows stale and only the bills remain to be paid, people think differently, and perhaps Lord Wolseley himself would doubt now whether the doctors should exercise an uncontrolled power of purchase. But there were also minor points raised by the "Report of the Committee" which were certain to be seized upon by military critics.

The combatant officers who have theories may be classed in two great divisions. The first clings to the old traditions of the service, when the regimental system was everything, and the doctor was the genial companion of the mess-table, the friend in need of every old soldier, and, above all, a civilian permitted to wear a red coat indeed, but never to be entrusted with military command, not even in his own hospital. The second and the younger division has accepted the inevitable. It recognises the fact that economy is a necessity, that regimental hospitals entail totally un-

necessary expense and monopolise the services of medical officers in routine duties, when they might be better employed in hard professional work at central hospitals. Of course there can be no agreement between men who hold such diametrically opposite opinions. "Unification" has an additional disqualification in the eyes of martinets; it renders *command* necessary; it requires that medical men should be supreme in their own hospitals; it obliges them to draw together into a scientific corps, whose members must necessarily become more independent, *not of military*, but of regimental rules and regulations. Offensive as this must be to the old-fashioned school of warriors, we are inclined to believe that the course of events will tend to benefit the service and the doctors themselves, and that a return to the regimental system, now that short service is the rule, would be an absurdity. The old soldier may have lost the friend who was supposed *to know his constitution so well*, but old soldiers are terribly at a discount. We have no idea that the young soldiers will suffer in the least from the unification system, and those who have a kind of grievance at losing the regimental doctor, the Colonel and officers and, above all, the officers' and soldiers' wives, must make up their minds to put up with the same kind of inconvenience which they had to suffer before they became members of regiments, and will have to suffer again when they return to civil life. But it was natural that in the discussion on the vote the upholders of the old system should vent their wrath.

Mr. Dawnay did his best to rake up all the old gossip of the campaign in Egypt, the want of puddings and pies, and other luxuries, which it is to be presumed would have been in the hospital larder under the regimental system. He pointed out that the orderlies were not half so polite as they should have been, and that the Medical Department seemed afraid of responsibility. He paid compliments to the members of the Committee for their recommendations generally, although one hardly sees why, as the members seem by no means of the same mind as Mr. Dawnay; but his anger overcame him when he denounced the recommendation that the medical arrangements of the Household Troops should be assimilated to those of the rest of the army. We were glad to learn from those who followed Mr. Dawnay, that unification was likely to be accepted as a rule, even if, for a time, the regimental system were retained in the Guards. The Marquis of Hartington put the plain facts before his audience when he said that unification was economically necessary, and had certainly not been attended by any evils which could affect the well-being of the sick and wounded. The intention of the War Office to consider at some future day the institution of a great Central London Military Hospital, seems indeed to indicate that even the regimental medical system of the Guards is doomed. In the meantime, unification must ensure progress which will benefit the Medical Department, the service and the nation generally, by encouraging more professional knowledge and surgical skill than could be generally acquired or maintained under the old isolated regimental system. Unification, of course, as it develops, will necessitate a stricter union between all who work together to help the sick and wounded, and place the doctors and the members of the Army Hospital Corps in one department, under one command, which of necessity must be medical. But surely this is not a matter for regret.

COMING LEGISLATION IN LUNACY.

In the House of Lords on Monday night a conversation took place upon the Lunacy Laws, the text for it being furnished by Baron Huddleston's remarks, which we have already quoted and commented on, concerning the facilities that exist for the incarceration of persons in asylums. Baron Huddleston's view is, as we showed at the time, erroneous; but there is no doubt that public opinion has reached a degree of intensity on this subject that will compel the Government to alter the law, and some alteration was explicitly promised by the Lord Chancellor on Monday. It is not difficult to see the direction that this alteration will take. It will be two-fold, and will deal, first, with the formalities to be gone through in committing patients to asylums; and, secondly, with the method of liberating them from private asylums. The intended legislation is not likely to affect in any material degree the arrangements for the committal and retention of pauper patients. No charge has been brought against these arrangements. They are carefully drawn, and they are found efficient in practice. Complaints against this system are extremely rare—are virtually non-existent, save in so far as they emanate from patients actually resident in asylums, and whose lunacy is undoubted. The complaints that are made are made against the system of incarcerating private patients, and the alteration that will be proposed will, in all probability, be in the direction of assimilating the procedure of committing private patients to the procedure already in force in the case of paupers. The main difference between the two modes of procedure is, that in the latter case the order must be signed by a justice of the peace; while, in the case of private patients, it may be signed by a relative or friend of the patient. The necessity of satisfying not only medical men, but also a magistrate, of the lunacy of a patient is a safeguard in which the public, rightly or wrongly, have great confidence. It is one which they are determined to possess; and it is one, therefore, that medical men must make up their minds to accept. Is there any reason why they should object to it? There is none. On the contrary, it will relieve them from a vast load of responsibility, without imposing on them any corresponding disadvantage. To the patient, the additional form to be gone through will not be an unmixed good. In so far as it fences about his liberty with an additional safeguard, it is of course an excellent provision; but in so much as it will act as a retardation to his committal it will to a certain extent militate against his recovery, for no fact in lunacy is better established than that the chances of a patient's recovery are the greater, the earlier he is placed under treatment in an asylum. This statement is, however, much more true of pauper patients, with whom the alternative too often is between treatment in an asylum and no treatment at all, than of private patients who can often be as efficiently treated at home as in an asylum.

It is the second point about to be taken in hand by the new legislation which will most affect alienists. We have already expressed in these columns the opinion that the system of private asylums is indefensible and that its abolition is a matter of time only. Lord Coleridge on Monday night spoke to precisely the same effect, and took the same view as has been taken by this journal. He spoke not of the men, but of the system. He said it was unwise to give any medical man an interest in retarding the recovery of the patient. As we have said before, so again we say now. The most important and the most urgent need of the psychological branch of the profession is to gain the confidence of the public, a confidence which doubtless they deserve, but which not the most sanguine of them can say that they possess; and it is hopeless, it would be unreasonable, to suppose that this confidence will be given to the administrators of private asylums so long as they remain in their present position. So long as a man has an interest in by his patient's retaining his malady, so long the public will mistrust him. There is only one possible solution of the question, and that solution will ultimately be as satisfactory to the profession as to the public; it is to abolish private asylums and substitute for them asylums managed upon the same plan as pauper asylums are now managed.

REVIEWS AND NOTICES OF BOOKS.

HIRSCH'S GEOGRAPHICAL AND HISTORICAL PATHOLOGY.[1]

The Council of the New Sydenham Society has done the profession in England a right good service in having brought the great work of Professor Hirsch, of Berlin, on "Geographical and Historical Pathology" within the reach of English readers; and it has been particularly fortunate in having enlisted the services of Dr. Charles Creighton in the very onerous task of translating so large a volume. A mere glance over the pages suffices to show how true are the words which the author has addressed to the translator—"A great portion of my life is comprised in this book, together with unspeakably wearisome labour." The present instalment is the second edition of the first volume, and deals with the acute infective diseases.

The volume opens with a chapter on *Influenza*—a disease which appears to have been known in the remotest times, and which extends over the whole habitable globe. It always occurs in epidemic form, and even on board ship epidemics of it have been recorded, the crews having been attacked just as suddenly and with as little warning, as when the disease appears on land. Instances are recorded, moreover, in which the epidemic broke out "while the ships were lying in port or cruising off the coast, no trace of the disease having shown itself, either before or after, in the same region ashore." One of these is particularly striking, where the crew of an East Indiaman was affected almost to a man during the voyage from Malacca to Canton. The disease was not present in Malacca when the ship left, but when she reached Canton it was ascertained that at the very time the disease was most prevalent on board ship it was also very prevalent at Canton. Incidents of this character, and other points in the natural history of the disease, such as the sudden occurrence of epidemic outbreaks—attacking the people *en masse*—their equally sudden and complete extinction, after a brief existence of from two to four weeks, and the restriction of the disease to one place, the surrounding country being exempt—"all these points," Dr. Hirsch writes, "are so foreign to the mode of development, and the mode of spreading proper to such maladies as originate beyond doubt through the communication of a morbid poison, that we shall find it hard to discover any reason for counting influenza among the contagious or communicable diseases."

An article on *Dengue* forms the second chapter, in which is given an exhaustive account of the history and literature of the disease. Apparently, the earliest account of it does not date farther back than 1779, when it appears to have been prevalent in Egypt, and to have been known as the "knee-trouble." In the following year a similar disease is recorded as having been met with in different parts of the world—Batavia, the Coromandel Coast, and at Philadelphia. From this period till 1870-73 various epidemics of it have been recorded, and especially during the years just cited, when the disease was very prevalent in India, the East African Coast, Arabia, Java, various parts of China, and other parts of the Eastern hemisphere. It has been observed that, as regards the suddenness of its appearance, and the rapidity with which the greater part of the population of a locality are affected, it presents a striking analogy with what is observed in influenza, and Dr. Hirsch consequently believes, for the same reasons, that dengue, like influenza, is not a contagious disease.

The third chapter, dealing with *Sweating Sickness* and *Miliary Fever*, is, perhaps, the most interesting in the volume, and contains a vast amount of information which the reader will search for in vain elsewhere. The term "sweating sickness" was first given to a disease which broke out among the troops shortly before the battle of Bosworth Field, in August, 1486. After this several outbreaks of the disease were observed, but it was confined entirely to England until, in 1529, it occurred over a large part of the Continent of Europe. Miliary fever appears to bear a very close relationship to it, and it has been observed that outbreaks of both forms of the disease have coincided with outbreaks of cholera, both as regards time and place. This was observed during the first outbreak of cholera in France in 1832, and again in 1849, but outside France the coincidence between the outbreaks of these diseases has not been observed except in Belgium and Luxemburg; or, perhaps, it would be more correct to say that attention has not so specially been drawn to the coincidence. It would appear that the latest records of pestilence show that some such

[1] "Handbook of Geographical and Historical Pathology," by Dr. August Hirsch, Professor of Medicine in the University of Berlin. Vol. I.—*Acute Infective Diseases*. Translated from the Second German Edition, by Charles Creighton, M.D. London: New Sydenham Society, 1883.

relationship exists between these particular diseases in different parts of the globe. An illustrative account is given of such an occurrence in India—at Mhow—in 1839; and Roux refers to such a sickness under the term *choléra cutané ou sudoral*, based on observations made in the Black Sea during the Crimean war. All the ordinary symptoms of cholera were present, except that profuse sweats took the place of the intestinal transudation. Beau, in describing the disease on board the French fleet in the Black Sea, writes:—"In 361 patients there were present all the most marked symptoms of algid cholera: cyanosis, icy coldness of the extremities and of the tongue, cold sweats running over the whole cutaneous surface in such quantity as to soak the linen of the patients in a few minutes, and to macerate their epidermis; absence of pulse at the wrist, extinction of the voice, rapid wasting, typical *facies choleraica*, very painful cramps, and sometimes suppression of urine. The characteristic vomiting and diarrhœa were all that was wanting in many cases; and therein lies one of the marked peculiarities of our epidemic. The copious diaphoresis, which we have dwelt upon, appears to take the place of the usual hyper-secretion from the intestine." The comments which Professor Hirsch makes on this, and other records of the occurrence of this disease, are very striking, and deserve the attention of all who are specially interested in elucidating the ætiology of cholera. One constant phenomenon is observed—a morbidly increased activity of the skin, partly taking the form of an abnormal transudation, partly breaking out in exanthems; and the analogy between the disease-processes, which form the subject of this chapter, and cholera, is so striking, that "on the first appearance of cholera upon European soil, Hufeland drew attention to the resemblance between it and the oldest form of sweating disease known to us—the sweating sickness of the English."

The space at our disposal will not admit of our giving even a brief epitome of the other chapters in the volume, such as those dealing with small-pox, scarlet fever, malarial diseases, relapsing fever, typhus and typhoid fever. The history and characters of these forms of sickness are better and more generally known than are the history and characters of the diseases which form the subjects of the first three chapters. The history and geographical distribution of cholera again is dealt with in an exhaustive manner; indeed, more than one-seventh of this volume is devoted to it; but as latterly this disease has formed the subject of such general discussion, we shall not do more than draw the attention of epidemiologists to the mass of information which will be found collected for them by Dr. Hirsch.

The chapter on *Plague* contains much that will be new to most English readers, and considerable information will be found in it regarding the form of this disease, known as "mahamurree" in some parts of India. The chapter, dealing with yellow fever also, will thoroughly repay perusal, and data will be found in it concerning every known outbreak since 1635. A marked feature in the geographical distribution of this disease is, that it has never been observed as an epidemic in Asia or Australia, nor in Europe and Africa, except along some parts of their western coast; and it has not extended farther north than the south-west coast of the Iberian Peninsula, although isolated cases have occurred in several of the more northerly ports of Europe; but the disease "never got to be generally diffused among the inhabitants." Practically, the area over which it prevails is limited to the shores of the Gulf of Mexico (including the West Indies), part of the Atlantic Coast of the United States, and a part of the West Coast of Africa.

We shall not attempt to offer anything in the shape of criticism on a work of this character. The evidence which every page affords of the labour involved in its preparation, is of itself sufficient to disarm criticism, unless, indeed, it were obvious that the labour had been wholly devoted to collecting material giving a one-sided view of the subjects discussed. No such charge as this can with justice be laid at Dr. Hirsch's door, for, to all appearance, he has gleaned his information from *all* the sources which have come in his way; and by giving the chapter and verse of each reference, he, practically, invites his readers to verify every quotation he makes. The deductions which he makes as to the ætiology of the several diseases must, of course, be looked upon apart. Different readers will put different interpretations on the evidence adduced; and, indeed, for our part, we feel inclined to think that too great a tendency is manifested by the author to refer the origin of diseases to "importation," or some such verbal equivalent, and sometimes on what appear to us to be very slender grounds. This, however, is merely a matter of individual opinion, and each reader can form his own. The great point is, that Dr. Hirsch has brought within our reach information which must have been gathered from many libraries, and which, indeed, could only be gathered by a proficient linguist, and a man of very exceptional erudition.

A word of praise to the translator and our pleasant task is done. Dr. Creighton has accomplished his part of the work with marked ability. A higher compliment could not be paid to a translator than to state that the work, from beginning to end, reads more like an original work than a translation, and Dr. Hirsch himself has given it his *imprimatur* in having read over the proof sheets. English readers are also indebted to Dr. Creighton for having compiled an excellent index to the volume.

A Guide to the Study of Ear Disease; by P. M'Bride, M.D. Edinburgh: W. and A. K. Johnston.—This little book is really what it professes to be, a guide to the study of diseases of the ear, "to meet the requirements of the student, and of the general practitioner who has not had the advantage of studying otology under the guidance of a teacher." Neither need go farther for what he requires on the subject, for in this work he will find it all, put briefly, clearly, and pleasantly. Each disease is described as shortly as is consistent with clearness, and while the author does not omit to mention the opinions and experience of others, he chiefly relies on his own. Hence his descriptions are so vivid and true, that (to take for example the diseases of the middle ear), after the beginner has mastered the difficulty of seeing the membrana tympani properly, he ought quickly to recognise, and

attribute to their right cause, the various appearances it presents in disease. We venture to think the author would have done better, if he had described acute purulent and non-purulent catarrh of the middle ear separately. Although we concur in his statements that "no surgeon would take upon himself to diagnose the exact form of exudation in a severe case of so-called acute catarrh, and that in these cases, as described in text-books, the secretion is as often purulent as mucous," still, as the two forms of inflammation differ in many respects in their treatment, it certainly seems to us that it would have been more convenient for practical purposes to have treated them apart. In acute non-purulent catarrh, the surgeon has practically to guard against the deafness which follows; in the purulent form, on the other hand, he has frequently to deal with complications arising when matter is found in the tympanic cavity. The author hardly makes this clear enough, as, by describing both forms of acute inflammation together, and treating of the complications arising during purulent catarrh, under the head of chronic suppuration, the unwary might be led to suppose that these complications only arise during the course of chronic suppuration. While on this subject, we would ask the readers of the book, not to take quite so desponding a view as Dr. M'Bride does, when he states that "in these cases of chronic suppuration, the discharge sometimes defies treatment." We firmly believe that every case of middle-ear suppuration can be cured by patient treatment, unless there be present tuberculous infiltration of the mucous membrane, or disease of the underlying bone.

Having found fault with the author on these minor points, we have nothing but praise for the rest of the book. On the subject of injection into the middle ear, his views are so sound, that we cannot do better than quote his own words. "It is claimed that such injections tend to cause absorption of fibrous tissue, by establishing a slight reaction; but it is somewhat difficult to credit this, for would the most sanguine believer in the deobstruent action of the iodide of potassium, expect a result from injecting a five, or even ten-grain (to the ounce) solution into the urethra, having in its course an organic stricture? If not, can we expect a more satisfactory result in the case of adventitious fibrous tissue within the tympanum?" All that is at present known about diseases of the internal ear, is clearly stated in a few pages, and will well repay perusal. Finally, the chapters on "tinnitus aurium," and "the diseases which affect the ear," are full of valuable information to others besides aural surgeons. The coloured drawings of the membrana tympani, at the end of the book, are works of art, and wonderfully true to life.

The Propagation of Tuberculosis; by Lydtin, Fleming and Hertsen. London: Baillière, Tindall, and Cox.—This little work is a translation of a report prepared for discussion at the International Veterinary Congress, held at Brussels in 1883, on the influence of heredity and contagion on the propagation of tuberculosis, and a brief account of the debate which took place on it. The recent delivery by Dr. Andrew of the Lumleian lectures on this subject having drawn attention thereto, it will probably be of interest to our readers to learn the principal conclusions at which the reporters arrived. As to heredity, they conclude that the disease is transmitted by the male as well as the female parent, and that tuberculous parents may transmit to their offspring a predisposition to tuberculosis. As regards the contagiousness of phthisis, they conclude that the disease in man and animals is transmissible by heredity, and also is contagious, and that it may be transmitted from animals to man by consumption of the milk of phthisical animals. As to the measures to be taken to prevent the injurious effects which might arise from the use of the flesh and milk of tuberculous cattle, they recommend amongst other things, that the meat should only be used for food when the disease is in a very early stage, and the lymphatic glands are unaffected, that meat showing a more advanced state of disease should be rendered unsaleable by being sprinkled with petroleum, and buried under supervision; the extraction of the tallow by boiling, and the sale of the skin might be permitted. The inspection of every animal affected with tuberculosis should be made by a veterinary surgeon, who can alone judge whether the flesh may be consumed, and lastly, the milk of animals affected with, or suspected of tuberculosis should not be used for the food of man, nor yet of certain animals, and its sale should be rigorously prohibited.

Bacteria and the Germ Theory of Disease; by Dr. H. Gradle, Professor of Physiology, Chicago Medical College. Chicago: D. T. Keemer. London: Trübner & Co.—The eight lectures delivered by Dr. Gradle in the Medical College to which he is attached, and now issued in book-form, can scarcely be termed an addition to the already formidable list of bacterial literature, seeing that they are altogether of the nature of mosaic work, being a compilation from the works of others with just so much of the personal element as is needed to give the fragments the requisite cohesion. As a course of lectures, in which—the time allowed being in inverse ratio to the extent of subject to be treated of—the object seems to have been to stimulate the interest of the audience by an analysis of contemporary opinion, they doubtless answered their purpose well; but the reason of their publication for general circulation is not apparent. They might, indeed, serve as a "popular" hand-book on a subject into whose working depths the general reader is not likely to be tempted; but they are too sketchy to be in any degree satisfying, and hardly even suggestive, to the real student. With respect to the author's own opinions, we gather that he more than suspects normal digestion to be dependent on bacterial agency; while *à propos* of the germ theory he writes with no uncertainty:—"The surgeon of yore did his best in the performance of the necessary operation, but the results following his wounds he could not control. The surgeon of to-day, however, is responsible for the course of the wound he inflicts. Any untoward accident, starting from the wound, is due to his want of care." The book is well printed, and furnished with a sufficiently copious index.

Human Anatomy; by C. J. Witkowski, M.D. Translated by Arthur Trehern Norton, St. Mary's Hospital. London: Baillière, Tindall, and Cox.—Part VIII. of this series consists of a movable atlas showing the bones and ligaments of the human body, accompanied by a descriptive pamphlet of 34 pages. We confess that the atlas entirely surpasses our powers of description, and there is no doubt that the author has expended upon it an amount of ingenuity that was worthy a better cause. The pamphlet consists for the most part of a series of anatomical ejaculations, interspersed with quaint remarks, the value and relevance of which are not quite apparent; *vide* page 22, where we are told that "Anna Boleyn, wife of Henry VIII., had six fingers on the right hand, and a supplementary breast." We cannot tell for what class of people this book has been written, unless, indeed, it is intended for the use of those who are engaged in the delicate task of teaching *Board-School Anatomy.* The plan of the work is so contrary to that upon which anatomy is usually taught in this country, and causes it to assume so grotesque a form, that we may be pardoned if we ask, whether the *author,* or the *translator,* possesses any sense of the ridiculous.

Ambulance Handbook for Volunteers and Others; by J. and A. Raye, L.K. and Q.C.P.I.; L.R.C.S.I.—This little work is dedicated to the members of the Volunteer Services at home and abroad, and consists of the text of a course of lectures which the author had intended to deliver to an ambulance class formed of the East Indian Railway Rifles, during the Tel-el-Kebir Egyptian campaign. It is just suited for its purpose, and may well serve as a text-book for the instruction, by surgeons of volunteers, of the bearer companies and ambulance workers under their charge. The book does not follow precisely the lines laid down by the St. John's Ambulance Association, and is, perhaps, on that account more suitable as a military ambulance handbook. The practical part of the book is the best. The anatomical and physiological sections are open to the objection, so often

alleged against all ambulance text-books, of teaching too much or too little—too much if the whole gist of such important subjects is to be disposed of in one or two lectures; too little if any real grasp of their mysteries is to be assumed as a result of so superficial a course of treatment. The sections relating to stretcher-drill, bandaging, and the use of ordinary instruments will be found useful and clear. The illustrations are numerous, well drawn, and instructive.

ABSTRACTS AND EXTRACTS.

ON THE ÆTIOLOGY OF TYPHOID FEVER.[1]

By Dr. GAFFKY.

Thirteen years have already elapsed since the first successful investigations were published of the part played in the production or spread of typhoid fever by micro-organisms. Professor von Recklinghausen demonstrated, in the year 1871, certain colonies of micrococci in suppurating kidneys in a case of typhoid, and thus opened the way for further enquiries, which have been actively prosecuted by many pathologists and histologists of note. Whilst all these investigations, however, have been followed by the discovery of micro-organisms, there has been wanting that absolute unanimity as to the identity of the "bacillus of typhoid," which is essential to its general acceptance.

In 1880 a definite form was described and identified by Eberth, especially in the spleen and lymph glands in fatal cases of typhoid; it was always found most abundantly in the most acute cases. Even in these, however, its appearance was not constant; it was, in fact, only observed in 18 out of 40 cases. No similar organisms were found in any other intestinal affections.

In some respects this bacillus corresponded to that observed by Klebs in 1878 and 1880, in the mesenteric glands and other viscera, and also in the larynx, in cases of typhoid ulceration of that organ. In form, however, these bacilli differed from those described by Eberth, being longer and more thread-like, although in their distribution they would appear to have closely attended the anatomical changes secondary to the typhoid process, wherever occurring.

Koch's investigations, published a year later, tended to show that short bacilli, corresponding to those described by Eberth, were present in a very large number of cases in the parts of the mucous membrane lying beneath the necrosed sloughs, and he could only find the thread-like organisms in the necrosed tissue itself. These he regarded as secondary, the bacillus observed by Eberth being the primary organism. An element of uncertainty, however, is present here also, owing to the different affinity which Koch's and Eberth's bacillus respectively appear to have had for colouring matters.

Corroborative observations have from time to time been recorded by Meyer, in Berlin, and by Coats and G. F. Crooke, in England, who have all found a short bacillus in the inflamed tissues in typhoid fever, which is in all probability identical with that discovered by Eberth and Koch.

Dr. Gaffky's investigations were made in 28 fatal cases of typhoid fever, and he only failed to find the bacillus in the mesenteric glands, spleen, liver, or kidneys, in two cases. In one of these, however, there were numerous bacilli found in the mucous membrane of the intestine; whilst, in the second, the typhoid process had fairly ceased, death taking place from accidental rupture and peritonitis.

The far greater success that attended his researches, than those of previous observers, he attributes to the wider range of his investigations. In the organs, the distribution of the colonies of bacilli was very irregular, and hence could only be satisfactorily determined by a very large number of observations. He found that the bacillus identified by Eberth and Koch was most frequently present in the lymphatic glands or in the recently affected tissues. After the disease had progressed, the work became much more difficult from the presence of numerous other bacterial forms, and amongst them the thread-like bacillus described by Klebs. Dr. Gaffky gives as the dimensions of these bacilli, which he apparently regards as undoubtedly specific organisms, one-third the length of an ordinary red blood corpuscle, the width being about one-third of the length; the ends were rounded off, as in the case of the bacilli observed by Eberth; a few spores were visible in some of them. With regard to their distribution in the organs, he found them in the greatest profusion in the intestinal mucous membrane in acute cases. In the mesenteric glands they were less frequently present than in the spleen. In the liver and kidneys also, they were only occasionally discovered. Of the manner in which the bacillus finds its way through the mucous membrane and so to the organs, there is at present no definite evidence forthcoming. The colouring matter employed was methyl blue, but the bacilli were found to be susceptible of staining by methyl violet, gentian violet, Bismarck brown, fuchsin, or even hæmatoxylin. The tissues required, however, to be exposed to the stain for a long time, and maintained at a gentle heat. Abundant micrococci were brought into view by any of these stains, but they were easily distinguishable from the special bacillus, and were generally confined to the mesenteric glands.

The cultivation of the bacillus in other than the tissues of the body has not been uniformly successful hitherto, owing, as Dr. Gaffky believes, to want of method, and especially to the practice which was at first adopted of employing fluids instead of peptone gelatine as the cultivating medium. In his own cultivation experiments small portions of blood were removed from organs known to contain the bacilli, and, with every possible precaution to prevent contamination, placed in peptone gelatine. The resulting bacilli corresponded exactly in form and size with the original stock. A new feature, however, was present in the shape of independent movement, the smaller bacilli moving hither and thither with varying rapidity, and the longer thread-like forms showing a distinct wavy movement. The bacilli appeared to reach their most perfect development about the fourth day. Unlike some other forms of moving bacilli, they produced no liquefaction of the gelatine.

Inoculated upon the surface of a freshly boiled potato the rapidity of development was found to be extreme; indeed, this property may be regarded as a characteristic of the typhoid bacillus. When transferred to some other cultivation fluids, the number and vigour of the newly-formed bacilli was at once diminished, whilst in the potato they again recovered their number and dimensions. The formation of spores was found to take place in from three to four days at a temperature of 30° to 42° C., but more slowly at lower ranges, and not at all below 20° C. The results of experiments, with a view to induce typhoid fever in the lower animals, have not been as yet by any means conclusive. Dr. Gaffky, after a very large number of experiments on a variety of animals, comes to the conclusion that all the attempts hitherto made have been unsuccessful. Reviewing the results of his own and other observers' discoveries, he maintains that we are now justified in regarding the bacillus as the true cause of the typhoid process. Without definitely pronouncing an opinion upon the point, he argues, from the analogy of other infectious diseases, that we may, for the present at least, regard this bacillus as an absolutely specific pathogenic organism. The history of its behaviour outside the human body, and whether its spores lie dormant or are capable of development in other media, must remain a subject for conjecture only.

With respect to the exact mode of infection, Dr. Gaffky is led to a definite expression of his opinion, that whether the spores or bacilli be swallowed in drinking water or in other forms of food, or whether they be inhaled, in every case they pass the stomach unaffected, and only become developed and actively reproductive in those parts of the intestine in which are situated the solitary follicles and Peyer's patches.

PATHOLOGY.

THE HISTOGENESIS OF TUBERCLES. — According to Professor Baumgarten, of Königsberg, the development of specific tubercles can be studied most easily and accurately in the changes which take place in the iris of albino rabbits after tubercular matter has been introduced into the anterior chamber of the eye. The first stage is the migration of the bacilli from the particles introduced into the iris tissue which at this period is perfectly healthy. The free bacilli themselves enter the iris, they are not conveyed into it by wandering cells, and when there they multiply and spread in the tissues. On the tenth or eleventh day after inoculation the iris still looks healthy, although bacilli can be found all over it, both in the intercellular substance and in the cells. In those spots where the bacilli begin to group themselves into nests, changes take place which always lead to the production of typical tubercles. Whilst in their normal condition the fixed cells of the stroma of the iris of albino rabbits have the form of thin plates, which appear if seen edgeways as free oval nuclei attached to the wall of the particular intercellular space under observation; under the influence of the bacilli these cells swell up to large cubic or polygonal masses of protoplasm (the epithelioid cells of tubercles of authors). The fibrillar intercellular substance becomes compressed and rarified by the pressure of these cells, and is more and more reduced to that delicate network known as the reticulum of the tubercle. Whether a hyperplasia and multiplication of the fixed connective tissue cells take place as well as this hypertrophy of the individual cells is not certain, but if it occur it must be in so slight a degree as to take only a subordinate place in the formation of tubercles. The giant cells of tubercles must at present be considered as rising from a fusion of several of these epithelioid cells and not from a multiplication of the nuclei of a single cell. The wandering leucocytes take no part in the formation of these epithelioid tubercles; a tubercle having this structure can be perfectly developed without the aid of a single leucocyte, and the few which wander into it in the course of its development perish—they shrink to irregular masses and ultimately break up into small granules. The number of bacilli in the nest which gives rise to one of these epithelioid tubercles in the iris of an albino rabbit is never very great even when the tubercle is completely developed, but the bacilli increase in number from day to day, and after some time an attack of iritis sets in, generally suddenly; there is a rapid dilatation of the blood vessels and numerous leucocytes migrate into the stroma towards the tubercles. If the tubercles are examined at this stage, we find they present the typical structure of a Wagner-Schüppel tubercle, a sharply contoured cellular mass containing no blood-vessels, the centre composed of epithelioid cells and generally one or several giant cells, the periphery for a zone more or less wide, composed of lymphoid elements, the whole penetrated by a delicate fibrillar network. The bacilli in the nest become more and more numerous, and this immigration of leucocytes into the tubercle goes on till the whole mass has the appearance of a small-celled lymphoid structure. The only subsequent changes which can possibly take place in a tubercle after it has reached this lymphoid stage, are those of degeneration and destruction. No lymph cell tubercle has ever been seen to change into an epithelioid or a giant celled tubercle in the iris of a rabbit. Other studies of the development of tubercles in other parts of the body and other tissues appear to show that tubercles always grow in a similar way, the different appearances depending on the rate at which the tubercles develop and at which the different stages follow one another. The rate of growth varies with the number and vigour of the bacilli; the more rapid the increase in the number of these, the more quickly does the primary epithelioid tubercle change into a lymphoid tubercle, and in very malignant cases the bacilli may multiply so rapidly that the epithelioid stage has such a short duration that the tubercles appear to be developed at once in the lymphoid stage, and consequently break down at a correspondingly rapid rate. On the other hand, the tubercles may retain their epithelioid and giant celled structure for a very long time when there are but few bacilli. From these observations we can understand how the pure lymphoid tubercles are the most malignant, and are only found in the worst cases, the mixed Wagner-Schüppel tubercles in more chronic ones and the almost purely epithelioid forms in cases of tuberculosis of lymph glands, lupus, tubercular disease of joints, &c.—*Centralblatt für Klinische Medicin* (No. 15, 1884).

THE BACILLUS TUBERCULOSIS.—The following are the results which Prof. Coze arrives at from an experimental investigation carried on in the laboratory of the Faculty of Medicine at Nancy. (1) The bacillus is recognisable by its form and dimensions, and especially by certain characteristics of colouring, which belong exclusively to it, and distinctly separate it from other analogous elements. (2) It is constantly met with in the expectoration of phthisical persons, and in organs the subject of phthisis, whatever stage of evolution this may be in. It is never found in the healthy portions of these organs, nor in other pathological conditions than that of tuberculosis. It presents the same characteristics in animals experimentally infected, so that the relation of cause and effect would seem to exist between the bacillus and the disease. (3) The existence of bacilli in the expectoration, in the organic liquids, or in portions of excised tissue enables us to establish the diagnosis of pulmonary tuberculosis with certainty. This examination is of great importance in doubtful cases, and in commencing tuberculosis, prior to the appearance of physical signs. (4) Up to the present time antiseptic medicinal agents have not, in an experimental point of view, furnished any positive results. Still, all reserves being observed, creosote appears to us justified as a means of treating phthisis.—*Bullétin de Thérapeutique*, March 30th.

NEW MODE OF STAINING THE BACILLUS TUBERCULOSIS. —In the *Philadelphia Medical Times* for January 26th, Dr. Hartzell advises the following method:—A small quantity of the sputum is spread thinly and evenly on a glass slide; when dried it is passed several times slowly through the flame of a spirit-lamp or Bunsen's burner. One or two drops of Gradle's fuchsin solution (Ac. Carbolic ♏ xv., Aq. ʒss., dissolve and add of saturated alcoholic solution of fuchsin ʒss.) are placed on the sputum, and allowed to remain for from three to five minutes. The slide is next thoroughly washed with distilled water to remove the excess of fuchsin, and the stained sputum is then decolourised by a saturated solution of oxalic acid. After being again thoroughly washed in distilled water, it is allowed to dry, and is then ready for mounting in glycerine or balsam. Under a power of 500 or 600 diameters the bacilli appear as brilliant red rods. While nitric acid—the decolourising agent usually employed—is disagreeable to handle on account of its corrosive and staining properties, it is also apt, unless great care be exercised, to remove the colour from the bacilli. Oxalic acid, however, appears to leave the dye in them untouched. In the *Boston Medical and Surgical Journal*, for February 28th, Dr. H. C. Ernest states that by this method *all* the micro-organisms which may be present are stained in equal proportion, and that it cannot, consequently, be relied on for the different diagnosis of *Bacillus Tuberculosis*.

GANGRENE OF EXTREMITIES FOLLOWING FORCIBLE EXTENSION OF JOINTS AND SUBCUTANEOUS RUPTURE OF ARTERIAL TRUNKS.—A valuable contribution to the literature of this subject is contained in a paper by Dr. F. Salzer, of Vienna, in the *Wiener Medicinische Wochenschrift*, Nos. 8 and 9, 1884. The occurrence of gangrene after forcible extension of joints is rare, and amongst a very large number of recorded cases, only four are to be found in which it was observed. Although pressure upon or injury to a main artery was diagnosed in these cases, the facts were never demonstrated by dissection. In Dr. F. Salzer's paper particulars are given of five cases of forced extension of the knee joint, in all of which gangrene of the leg followed in from two to six days. Amputation having

become necessary in each case, a thorough examination of the joints was possible and resulted in the discovery of rupture of the popliteal artery to a greater or less extent. In some cases the vein also was found to have been torn across. In all the cases there was more or less inflammatory adhesion around or within the joint, and it is probably to this fact that the want of collateral circulation must be attributed, coupled with the effects of pressure exercised by the hæmatoma formed about the seat of injury. No mention is made of the condition of the nerve trunks, from which it may be fairly assumed that they were found intact. A case of subcutaneous rupture of the femoral artery, followed by gangrene of the leg, is published by Dr. Weitz, of Pyrmont, in the *Berliner Klinische Wochenschrift*, No. 7, 1884, in which also the great effusion of blood into the soft tissues of the thigh appears to have hindered the establishment of collateral circulation. A further series of two cases of gangrene from a similar cause, by Dr. C. Jüngst (*Berliner Klinische Wochenschrift*, No. 15, 1884), is remarkable from the nature of the injury to the vessel. In the first case, with comminuted fracture of radius and ulna, a rupture was discovered in the intima of the brachial artery, close to its bifurcation. The middle and outer coats were somewhat stained by hæmorrhage into them, but no blood had found its way through them. A thrombus was formed above this point exactly in the same manner as after ligature of a vessel. In the second case, a similar condition was found in the popliteal artery, after a comminuted fracture of the upper part of the tibia and fibula. The absence of collateral circulation was very marked in both cases, the only explanation for which was the extent of the local injury. The frequent occurrence of disturbed circulation, and even of local gangrene after injuries to the forearm, must not be overlooked in considering these cases. Frequently such conditions are observed and attributed, without further question, to the influence of splints or bandages. A slight rupture of the intima of the arterial trunks may, as these cases prove, be produced as part of the first injury to the limb, and it may not improbably give rise, in some cases, to only temporary disturbance of circulation.

The Micrococci of Epidemic Cerebro-Spinal Meningitis.—Micrococci have already been found by Klebs, and again by Eberth, in cases of meningitis, complicating pneumonia, and in traumatic meningitis, whilst Leyden has described numerous micrococci, generally united in pairs, but often in chains of three, as occurring in a case of cerebro-spinal meningitis. Marchiafava and Celli have been able to follow up this line of research by utilising the cases of an epidemic of cerebro-spinal meningitis, which were brought to the Spital S. Spirito. In two of these cases, they were enabled to make the autopsies, and examine the exudation and the pia mater a few hours after death. In all their preparations made from the exudations, oval cocci were found either occurring singly or united in pairs. These were either free in the intercellular fluid, or in the protoplasm of the pus cells, they were only rarely found in the endothelial cells, some of the pus cells contained even six or seven diplococci. They did not find any chains of three. These cocci were relatively more numerous where the amount of exudation was small. From both these cases similar preparations were made from the blood taken from the right side of the heart, and from the pulp of the spleen, but no micrococci were found in any of these. On examining the pia mater, they found similar micro-organisms, lying in groups in the intercellular fluid.—*Gazz. degli Ospitali* 1884, No. 8.

Traumatic Malignancy in the Domesticated Animals.—Dr. W. H. Birchmore's investigations published in the *New York Medical Journal*, December 15th, 1883, were, he states, originally undertaken in order to obtain material for illustrating the inflammatory origin of tumours. "In the dumb animals only can we find very young growths and remove them at our will, or remove all the neighbouring tissue and appreciate its relations." Now, when the relations between the diseases of man and his dependent cousins are being realised, we find indications that, "besides enteric fever, pneumonitis, and tuberculosis, another vice of nutrition is shared by us all." The author gives about a dozen cases, including that of a chicken, whose humerus had been broken, some months later the un-united fracture was surrounded by a large ovoid tumour which proved to be a large round-celled sarcoma; encephaloid disease of the tarso-metatarsal bone in an old hen, following frost-bite; a capon, the site of whose right testicle was occupied by a tumour as large as an egg—an adenoid sarcoma; osteo-sarcoma of the jaw of a setter following gunshot injury; a large, mixed spindle and round-celled sarcoma from the lower lip of a mule, caused by irritation of the bit; a connective tissue tumour with nests of pseudo-epithelial cells, developed from an ulcerated papilloma behind a horse's ear, irritated by the rubbing of the bridle; a nodulated mammary cancer of a cow's udder following injury. Epithelial tumours at the point of the shoulders in ill-used horses are not very rare; villous tumours of the intestines are frequently found in hogs. "There is need of much more knowledge than we have in relation to these troubles—of their ætiology—and the only way of obtaining it is by the study, not of books, but of the things themselves."

Tuberculosis of the Testis.—A labourer, aged 38, had hydrocele, cause not determined; he denied syphilis. Volkmann's operation was successfully performed; five weeks later the patient returned with a history of rigors, insomnia, and loss of flesh. The testicle was then removed, and was found to show central tuberculosis, the hard tubercular mass not having yet had time to break down. A second patient, aged 31, had suffered from acute traumatic orchitis and epididymitis. Six weeks after the injury, the testicle was painful, swollen, and hard; the swelling extending some distance up the cord. Chilliness and sweating were also complained of. The testicle, when removed, exhibited incipient breaking down of the tuberculous deposit centrally; while the tunica vaginalis, instead of being smooth and firm, closely resembled the synovial membrane in cases of tuberculosis of the joints. In a third case, there had been chills, emaciation, loss of appetite, and swelling and pain of the testicle; the organ was found to consist almost entirely of broken-down tissue, and the tunica vaginalis had become obliterated. Dr. Gerster, who exhibited the specimens before the New York Pathological Society, remarked that in such cases the diagnosis could now be made much earlier than was formerly done, thus leading to proper treatment by extirpation; whereas it used to be the practice to let the condition remain until a fistulous opening formed in the scrotum, producing the so-called hernia testis. In the patients above mentioned, no physical signs of tuberculosis were detected in any other organs of the body; the general symptoms—rigors, sweats, &c., disappeared on removal of the diseased testicles.—*New York Medical Journal*, February 23rd.

Dentigerous Cyst of the Lower Jaw.—A remarkable instance of this affection is described in the *Chicago Medical Journal*, by Dr. J. S. Marshall. A girl, aged 16, came with a swelling over the first lower molar on the left side; the wisdom tooth on that side had not appeared, and the second molar was quite loose. Puncture showed that the swelling contained clear serum. Two months later, the swelling having meanwhile rapidly increased in size, its removal was agreed to, and accordingly it was laid freely open by an incision in the mouth. It contained about four ounces of thick dark yellow serum, and some pus, the undeveloped wisdom tooth was found at the base of the coronoid process, and removed. The condyloid process, and posterior part of the ramus, were separated from the coronoid process and the anterior portion, and detached from the surrounding tissues, the periosteum having been separated from this portion of the bone: this was removed through the cyst and incision in the mouth. The cyst was found to have extended so far upwards and backwards, as to nearly sever the condyle from the coronoid process, and body of the jaw; the condyle was separated from its fibro-cartilage, and showed evidences of necrosis. Finally, the lateral walls of the cyst were crushed. The patient made

an uninterrupted recovery, and two and a half years after, there was only a very slight flattening in the region of the angle of the jaw visible, and the movements of the joint were perfect.—*Journal of the British Dental Association*, March, 1884.

HYPERTROPHIED HEARTS.—Dr. C. W. Dulles showed to the Pathological Society of Philadelphia, on Dec. 13, 1883, the heart of a rheumatic patient, æt. 18. When all the adherent parts had been removed, the heart weighed 48 ounces: emptied of bloodclot and well washed, it weighed 40 ounces: the pericardium was universally adherent, but all the valves and bloodvessels were healthy, although the mitral orifice was enormous, measuring two and a half inches in diameter; the kidneys were in a condition of "cyanotic hypertrophy." At recent meetings of the Pathological Society of New York, similar specimens were exhibited, weighing respectively 55 and 57 ounces.—*New York Medical Journal*, December 29th, 1883.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON,

TUESDAY, MAY 6TH, 1884.

J. WHITAKER HULKE, F.R.S., President, in the Chair.

Report of Morbid Growths Committee.

MR. BOWLBY read the report on Dr. Norman Moore's case of enlarged ovaries in connection with cirrhosis of the liver. There was a general increase in all the tissues of the ovary. The cortex was abnormally dense, owing to increase of fibrous tissue. The greater part of the rest of the ovaries was composed of cells similar in shape and size to the nuclei of involuntary muscular fibres. They were embedded in a homogeneous matrix. The enlargement was thought to be of the nature of hypertrophy rather than of chronic inflammation or cirrhosis.

Three Cases of Tumour of the Lung.

DR. SAMUEL WEST exhibited these specimens and gave the following account of the cases:—(1.) A youth, aged 18, who had had his thigh amputated for osteo-sarcoma some months previously, came under observation suffering from pain in the chest, dyspnœa and palpitation, about 50 ounces of blood-stained fluid were removed from the left pleura by aspiration. At the necropsy several massive tumours were found in each lung, soft and spongy on the surface, but very hard within. They were of the same nature, viz.: osteo-sarcoma, as the original tumour of the leg. There were no secondary growths elsewhere, and the stump was healthy. (2.) A man, aged 39, had been ill for a month, when he came under observation with what appeared to have been pneumonia. Some effusion was found at the right base, but the removal of this did not bring much relief. On *post-mortem* examination, at the root of the right lung, surrounding the bronchi and vessels and compressing them, was found a mass of new growth extending into the lung substance along the course of the large bronchi. Microscopically, the growth was found to be scirrhus. (3.) A man, aged 62, whose physical signs exactly resembled those of the last patient, the *post-mortem* appearances were similar, except that the tumour was of small extent, sending processes only a very little way into the lung substance. As in the other case there were œdema and inflammatory changes, which had gone on to the formation of a cavity. The tumour in this case was also scirrhus. These two last cases were instances of what were commonly called primary tumours of the lung. But this was a mistake, for they originated in the lymphatic tissue at the root of the lung, and only affected the lung by direct extension. They were distinct both from tumours of the lung substance, and from mediastinal tumours. The former were very rare as primary, but common as secondary growths. The first case was in his opinion one of secondary growth. The points in the two last cases were, that the disease was nearly always unilateral, starting from the root and radiating inwards along the branches of the bronchi. All the structures at the root were compressed by it, and the result was that there was collapse and œdema of the lung, with inflammatory changes, often followed by breaking down of the lung substance, and the formation of cavities by a species of necrotic degeneration. These cavities were not, as was sometimes said, the result of the softening of cancerous nodules, and they contained only the products of lung tissue. The diagnosis, both from ordinary phthisis, and from mediastinal tumour, was often very difficult.

The PRESIDENT said the cases were of the greatest interest. As to the ones originating in lymph tissues at root of the lung he thought they would in penetrating the lung go against the lymph path according to Dr. West's hypothesis, which seemed improbable.

Dr. NORMAN MOORE thought they might be endotheliomates, taking origin in the pleura or pericardium and spreading thence to the lung. As to the first specimen, it would be worth while to collect all the cases of secondary growth in the lungs after disease of some or other of the bones.

Dr. EWART had several times seen secondary growth after cancer of the breast, and had seen the growth spread along the lymph path in the way described by Dr. West, he had seen two cases of osteo-sarcoma of lung secondary to tumour in the bones. He mentioned the case of a girl, aged 10, ill with dyspnœa; after a time consolidation was detected; a mediastinal tumour of rather rapid growth had made its way into the auricle, this led to the conveyance of growth into the lung substance, so that the lung was affected both in this way and by direct extension.

Mr. BOWLBY said, referring to Dr. West's first case, the original tumour was a central one, an ordinary fibro-sarcoma, not very malignant as was supposed. The others could not have originated in epithelium; one of them closely resembled the endotheliomata.

Dr. WEST said that he was willing to admit that his cases might possibly have been instances of endotheliomata. As to the growth not being able to advance against the lymph stream, he hoped to bring forward shortly a case of cancer of the gall bladder, in which it was evident that such a mode of spreading had taken place.

A Case of Supposed Actino-mycosis.

Mr. TREVES showed a drawing of a man, aged 46, a villager. Two years ago a swelling had formed over the left lower jaw, it grew slowly, it was incised a year ago, and never healed; an ulcer forming, a fresh lump appeared in the neck and broke down. After this other nodules appeared on his chest, all in the line of gravity. These fungating masses started as small nodules, which gradually enlarged, suppurated, and then formed the ulcers. The symptoms were typical of the disease (actino-mycosis) as described by Ponfick. The man had nothing to do with animals, and no fungus could be found. All the masses were removed and scraped away; the disease seemed to have no connection with bone. The wounds healed well. Afterwards he removed some growths from the axilla, followed by hæmorrhage; eventually the man died a month later. At the *post-mortem* there were secondary deposits in the lung, liver, kidney, and spleen. Mr. Cheyne could find no micro-organisms, and inoculation had failed. Microscopically some of the deposits had an alveolar appearance,

others showed clusters of round cells. It was to be noted that each nodule suppurated early, and that the disease was very protracted. He suggested it should be referred to the Morbid Growths Committee.

The PRESIDENT recollected the patient, and had felt the difficulty of diagnosis; he had rather inclined to a diagnosis of farcy.

Mr. WATSON CHEYNE detailed the steps he had taken to determine the presence of an actino-myces, but had failed, both in cultivation and inoculation experiment, to detect any organism, therefore tubercle and farcy were both excluded as well.

Mr. TREVES said, in reply, that the question of farcy had been raised, but the case had lasted too long for that disorder.

Cast from the Trachea.

Dr. BURNEY YEO said that a gentleman who had had symptoms of thoracic aneurysm, had for three days suffered with violent coughing, and brought up the specimen exhibited, the sputa about that time being a little blood-stained. It was one and a half inch long, three quarters inch across and bifurcated, it was hard and tough. He would not express any opinion as to its nature. It was referred to the Morbid Growths Committee.

Lardaceous (?) Syphilitic Disease of Supra-renal Capsule.

Dr. TURNER said the specimen was taken from a man, aged 34. The capsule was greatly enlarged, it was not lobulated, there were several natural fissures. It was an inch thick. The centre was traversed by numerous wide vascular channels, corresponding with the medullary part; this shewed a large number of spindle-shaped nuclei. The walls of the vessels were much thickened. It was an instance of syphilitic growth invading the supra-renal body. After referring to the works of Virchow and Dr. Greenhow on this subject, he pointed out that there were muscular fibres in the capsule, and that there might be some association with those in the trabeculæ in regard to the function of these organs.

Multiple Exostoses.

Mr. SYDNEY JONES exhibited a case containing nearly all the long bones in the body, presenting numerous exostoses, one femur showing an especially large one. He said they were taken from a man, aged 55; they were all covered with cartilage, and mostly in the shafts of the long bones, and not confined to the neighbourhood of the joints.

Fibro-myoma of the Stomach.

Dr. PERCY KIDD showed this specimen. The tumour had given rise to no symptoms during life; it was found in connection with the cardiac orifice of the stomach in a patient who died of abscess of the liver. The growth which was tough, whitish, and of a somewhat uniform shape, seemed to spring from the submucous tissue of the stomach, and had no obvious connection with the muscular coat. It partially encircled the œsophageal opening without causing any stenosis. The stomach elsewhere was healthy. The microscopical characters of the tumour were those of a fibro-myoma, the prevailing structure being myomatous. Such tumours were decidedly rare, they were usually small and commonly situated towards the cardiac end of the stomach. The present specimen exceeded in size the largest tumour of the same nature mentioned by Virchow in his "Krankhafte Geschwülste."

Dr. NORMAN MOORE mentioned the case of a little girl, aged 11, suffering from mitral disease, and very anæmic. There was a growth at the cardiac orifice of the stomach, which had ulcerated, and caused peritonitis.

Dr MONEY mentioned a case in a child, aged 6, in which there was a growth in the stomach, but it had not yet been examined.

Tumour of Scalp.

Mr. LOCKWOOD said that the tumour which he had removed from the head of a child had been noticed since an early period of life. There was a large mass behind the ear which proved to consist of hyaline cartilage. The growth itself consisted of round and spindle cells. He knew of no recorded case similar to it.

Mr. BOWLBY said the ingrowth composed of mucous cells had resembled epithelioma in the mode of spreading. He did not think there were any cartilage cells.

It was referred to the Morbid Growths Committee.

Lymphoma of the Intestine.

Dr. SILCOCK said the specimen was taken from the body of a child aged four, who had symptoms of intestinal obstruction. The lower part of the jejunum and ileum were very white, and their walls infiltrated with a new growth travelling in their mucous and sub-mucous coats. It was a lymphoma, with lymphoid cells set in a retiform stroma.

Cystic Tumour of the Spleen.

Mr. KNOWSLEY THORNTON said that it was noteworthy that the walls were so thin that cholesterine scales could be seen floating in the cyst through the abdominal walls. The cyst was multilocular. The patient had had no bad symptoms, and was now convalescent.

Card Specimens.

Dr. CARRINGTON. Malposition of kidney, arrested development of left side of uterus, absence of left ovary and Fallopian tubes.

Mr. SYDNEY JONES. (1) Exostosis and loose cartilage from the knee-joint; (2) Stomach after excision of cancer of pylorus.

Dr. PERCY KIDD. (1) Tuberculous ulceration of pharynx. (2) Polypoid tumour of the left ventricle.

Dr. HALE WHITE. (1) Atrophied bones of the arm after posthemiplegic rigidity. (2) Intestinal obstruction from old pelvic adhesion. (3) Thoracic aneurysm in a woman.

Dr. TURNER. Pistol shot fracture of cranium.

Dr. HOBSON. Malignant disease of cæcum.

Mr. SUTTON. Diseases of the ductless glands in wild animals.

Mr. SWINFORD EDWARDS. A cyst on the ulnar nerve.

Mr. LANE. Specimen of ununited fracture.

Mr. HORSLEY for Mr. HEATH. Recurrent myxœdematous tumour.

Mr. KNOWSLEY THORNTON. Mass of hair removed from a stomach.

Dr. GOODHART. Tumour of the pituitary body of an anubis.

Dr. SAINSBURY. Tubercle of brain.

Mr. ALBAN DORAN. Broad ligament-cyst developed above the Fallopian tube.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, APRIL 7TH, 1884.

Mr. J. S. TURNER, M.R.C.S., L.D.S., President, in the Chair.

Union of Fractured Incisor.

DR. BELLISARIO, of Sydney, New South Wales, read notes of the case of a gentleman, aged 27, who was thrown out of a dog-cart, striking his face against the stump of a tree. Three of the upper incisors were displaced and the fourth broken across transversely; the lower fragment could be

moved about in any direction, though with great pain to the patient, and crepitus could be distinctly felt. The displaced teeth were brought into their proper position and a thin gag inserted between the molars; only liquid nourishment was taken for several weeks. In the result, not only did the dislocated teeth become fixed, but the fractured incisor also united firmly, and at the end of three months all four were as strong and useful as they had been before the accident, and quite natural, both in appearance and sensibility.

The Influence of Micro-organisms in the Production of Dental Caries.

Mr. Arthur Underwood read a paper giving the results of further investigations on this subject, made by Mr. Milles and himself since the date of a former paper read before the Dental Section of the International Medical Congress in 1881. In this they had shown that certain forms of micro-organisms were invariably present in carious dentine; that no change resembling caries could be produced in the absence of these organisms, *i.e.*, under aseptic conditions; and that under septic conditions a change could be produced artificially which, if not undistinguishable from ordinary caries, certainly resembled it. The fact that organisms were invariably present had since been confirmed by numerous observers. It had been stated by one investigator—Dr. Miller, of Berlin—that the dentine was first softened by acid, that the invasion of micro-organisms was only secondary to this, and that a zone of softened dentine not infected with organisms always existed in advance of that which was so infected. He and his colleague, Mr. Milles, had, on the contrary, always found that the organisms extended as far as the softening; they could not find any softened tissue which did not contain micro-organisms, and they were of opinion that the acid which softened the dentine was produced by the organisms, just as occurred in ordinary processes of acid fermentation. They had cultivated the various organisms found in carious dentine in flasks containing purified blood serum, after the method introduced by Professor Koch, and had ascertained that there were several distinct varieties, but experiments made with the view of finding out which of these were the most active agents, gave negative results. Dr. Miller had stated that he had produced, artificially, caries which he defied anyone to distinguish from that which occurred in the mouth. Messrs. Underwood and Milles had repeated his experiments, and had tried several of their own, but with very partial success, for though a change resembling caries did take place in some instances, it invariably became arrested before it had gone very far. This comparative failure was no doubt caused by the difficulty of assembling in a flask or incubator experiment all the various conditions which were present in the mouth, and instances were quoted from the experiments of Koch, Pasteur, and Nægali, to show that micro-organisms, cultivated under conditions not altogether favourable, became weakened, and even lost their special attributes, so that the bacillus of anthrax, for instance, could be inoculated harmlessly. The authors of the paper claimed to have established that micro-organisms of a special form were an essential element in the production of dental caries. Food gets lodged between the teeth, and undergoes fermentation with formation of acid and bacteria; the acid destroys the enamel, the micro-organisms invade the dentine, and proliferate in its tubes, living at the expense of its organic material, their advance being accompanied by decalcification of the intertubular substance.

A discussion followed, the tone of which was distinctly favourable to the adoption of the views promulgated by Messrs. Underwood and Milles, which, it was remarked, would clear up some points which the purely chemical theory of caries did not explain, *e.g.*, the fact that the dentine was destroyed more rapidly than the enamel. And a hope was expressed that the discrepancies at present existing between the results arrived at by Messrs. Underwood and Milles, and those of Dr. Miller, might soon be settled by the help of independent testimony.

INTERNATIONAL HEALTH EXHIBITION.

INTRODUCTORY ARTICLE.

With due ceremony the greatest temple ever reared to the Goddess Hygeia opened yesterday, the 8th instant.

Our medical readers, through the medium of the daily journals, already know the origin, the scope and objects of the Health Exhibition, and we will not weary them with tales many times told, but in this and succeeding articles criticism will be our aim, the criticism of an expert, from an expert's point of view.

The Executive Council of an undertaking like the present Exhibition is, above all things, bound to make the venture popular and attractive; a financial failure is most to be dreaded, and hence they are perfectly justified in adding attractions and novelties which have but a remote connection with sanitary science. This we allow; nevertheless it is somewhat startling to find the hygiene of the camp and the vessel practically omitted. It surely might have been expected that the foremost naval power in the world would show various methods of ventilating ships—of feeding, clothing, and protecting sailors. Where are the countless appliances illustrated which have enabled, in modern times, British Armies to pass unscathed the malaria of the march, and the plague of the plain? The explanation of these omissions is to be found possibly in the constitution of the Executive Council. Strangely enough, no single member, except Dr. Buchanan, is officially engaged in the sanitary administration of the country. We presume that in any less enlightened land it would have been thought essential, for success and completeness, that half of the Council should be composed of health officers; but in England the rule is to place men in authority who have the advantage of being untrammeled by the prejudices of special knowledge.

The Exhibition has a twofold aspect—the aspect of a Show and a Lecture Room.

The old London street, the 5,000 electric stars, the long rich galleries, the throng of people from every clime, and the waters of the fountains gleaming with an inner weird light, make the exhibition as a spectacle unsurpassed, and render actual the impossible of the Arabian romances.

The handbooks, the conferences, the lectures, the Parkes Museum exhibit, the model dairies, the processes for the utilisation of sewage, and others are so many popular lessons, which will interest each visitor according to his receptive power.

The centre-piece of old London, is a quaint and costly work; the builder (Mr. Williams) estimates the cost roughly at 15,000*l.*; some of the printed descriptions have given the erroneous impression that as it stands it is an actual copy of a portion of the ancient city, but this is far from being the case; a large number of old prints, representing more or less celebrated houses in different parts of London,

have been collated, and from these a selection has been made, the period of the houses represented ranging as early as the fourteenth, and as late as the early part of the seventeenth century. It is scarcely necessary to say that the ground plan, as well as the interiors of the houses, are constructed entirely from imagination, supplemented by such hints as may exist in printed descriptions; the width of the street is also supposititious, and the surface drainage, which probably was then the only drainage, is not represented. Very fortunately, also, the garbage-sodden and odorous surface of the street will have to be left to the imagination. The models will bear a close comparison with the prints; all the details of external structure and ornamentation have been faithfully copied, the size of a few of the houses has been a little reduced, but mostly the size is presumed to be the same as represented in the prints.

"The Rose," of Fenchurch Street, "The Cock," of Leadenhall Street, "The Three Squirrels," "Whittington's House," "Elbow Lane," and "The Butcher's Row," will be to archæological minds delightful, but the professed sanitarian will regret that it was not possible to give some more true picture of the ancient city. Supposing 400 years hence nineteenth century London, vanished and half forgotten, has to be resuscitated in a similar way, what ideas would our ancestors gain of it by erecting Bennett's of Cheapside, Quaritch's of Piccadilly, Squire's of Oxford Street, Whiteley's of Westbourne Grove, the Holborn Restaurant, the First Avenue Hotel, and St. Pancras Church, in a double row, leading into Clare Market? Nevertheless these wood and plaster phantoms, evoked from their imprinted shadows, will without doubt attract thousands, and tend greatly to the success of the exhibition.

All that relates to the construction of healthy dwellings, from the first concept of the general design on paper, to the crowning actuality of chimney pots, is represented; there are bricks, floors, doors, windows, grates, mantel-pieces, tiles and cowls, in endless variety. There is also in construction a representation of a sanitary house, and one the reverse of sanitary. The latter is of course full of defects—damp, close, unventilated, the drains untrapped, the over-flow pipes from the cistern in communication with the sewer, and every ingenious appliance for letting as much bad air in and keeping as much good air out as possible.

In the models of artisans' dwellings, No. 388, Class 20, there is a distinct departure from the ordinary lines, and an attempt to grapple with the tenement question by boldly proposing to build a block in which each room shall contain a family, and in which several ingenious appliances are used to overcome the inconveniences and imperfections of this mode of living; but the details of this important group of exhibits must be left for one or more special articles.

Every hygienist will look with great favour on the competition between the electric lighting companies. Our dream is that, within the next five years at least, every public theatre and hall in the metropolis will follow the good example of the "Savoy," and abolish for ever the glowing alembics distilling carbon and sulphur dioxides, and adding their quota of heat and discomfort to that already emanating from a crowd. When all things are in full swing, twenty-two companies will exhibit; 5,000 of the lamps are incandescent, 300 are arc lamps. The incandescent lamp, in its steady glow, in its feeble heat, and in its general applicability to what may be called æsthetic illumination, is the domestic light of the future; it is scarcely possible that so uniform a light can injure sight in any way. The objections raised by the oculists in the earlier stages of electricity, when the light was a series of flashes, once well founded, are now wholly theoretical.

The three model dairies are well worth the study and attention of all; we have long been of opinion that the public supply of milk should only be in the hands of persons of considerable capital, for they alone can afford the necessary appliances, and take the necessary precautions which will minimise, as far as possible, the danger of drinking an animal secretion.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The ordinary monthly meeting of the Council was held on Thursday last, May 8th. The chief business transacted was the consideration of the Report of the Meeting of Fellows and Members on the 24th March. The first part of the Report dealt with the alterations proposed by the Council; which were of course received and passed. The proposals made by the Fellows and Members at large were next discussed. Concerning the resolutions that Fellows and Members be invested with a larger share in the management of the College, and that no alterations in the constitution or relations of the College be made without the consent of the Fellows and Members; it was resolved that no action be taken. The next resolution was practically carried, by the motion, that an Annual Meeting of the Fellows and Members be called to which a Report of the Council be presented. The next resolution concerned the mode of electing the President. It was moved by Mr. Heath, and seconded by Mr. Cadge, that the question be referred to the Committee on Charters and Byelaws to consider the same, and report thereon to the Council. To this an amendment was moved by Mr. Hulke and seconded by Professor Humphrey, that the election of President should, as at present, rest in the Council. The amendment was carried by a majority of 13 to 5—and was subsequently carried as a substantive motion. After the action of the Council it would not be necessary to alter the Charters, and hence the motion to this effect was not considered. The motion to combine with the College of Physicians and grant a title of Doctor to doubly qualified candidates was considered, and it was decided to take no action in regard to it. Sir Erasmus Wilson's resignation of his seat on the Council was next considered. It was accepted with expressions of regret for the cause of his retirement, and with a vote of acknowledgment of his liberality towards the College, in founding the lectureship associated with his name, and in other ways, and of his zeal in the service of the College. The President and Vice-Presidents presented their report on Mr. Quain's motion, that busts of past conservators be placed in the College; they advised the council should not act on it. Mr. Tweedy's letter concerning the resignation of certain Members of Council no longer in actual practice, which was referred to the President and Vice-Presidents, was further considered. It was decided not to take action, inasmuch as one gentleman to whom it referred had retired, and the other goes out of office in July next. Mr. Treves was introduced to the Council, and received his Jacksonian Prize. A letter was then read from the Hon. Secretary of the Poor Law Medical Officers' Association, asking the Council to petition the House of Commons, and the Local Government Board to make the Permissive Clauses of the Superannuation Act compulsory. Sir James Paget moved a vote of thanks to Dr. Arthur Farre, for the valuable collection of pathological drawings which he had presented to the College; this was passed unanimously. It was decided that the pass and pluck list be no longer published. The usual resolution for holding the annual meeting of Fellows for the election of Members of Council, in July next, was proposed and adopted. The Council then adjourned.

MEDICAL FEES IN GLASGOW.

In closing the session of the Medico-Chirurgical Society of Glasgow at the meeting held on the 2nd instant, Professor W. T. Gairdner, President of the Society, made the following remarks :—

Before sitting down he might mention that within the last few days his attention had been directed to an editorial article in the *Medical Times* of Saturday last, bearing on an important public institution in Glasgow, in which, as some of those present must be aware, there had been on more than one occasion differences between the lay directors and the medical directors, the medical and surgical staff of the institution being presumed to be in sympathy with the latter, but having on the most recent occasion been entirely ignored by the management. In commenting upon the dispute, the *Medical Times* put the following question [Dr. Gairdner read the article in question from the *Medical Times* of April 26th, page 562]. Now he had not the faintest idea who the writer of the article was, and he did not want to know. But it was evidently written by some one having access to local sources of information, and disposed to read a lesson out of the facts to the profession in Glasgow—a lesson which, being well intended, ought to be taken in good part. Therefore, let them, as medical men in Glasgow, ask themselves how far the facts were as the writer put them. If he were disposed to answer the question put, it would be in some way like this: that within his own knowledge the public estimation of medical men in Glasgow, as indicated by the test of the remuneration given to them, had been rising enormously during a considerable number of years. Coming, as he did, in contact with all classes of the profession in the city and neighbourhood, he had a fair amount of knowledge of the facts as regards especially the better class of practice, to which the article pointedly referred. Now he knew that within the last 22 years, during which he had lived in Glasgow, the fees of Glasgow practitioners in good practice had risen enormously; and he sincerely hoped that this very great improvement had not been altogether confined to the better class of practice. To him it would appear a thing improbable and, if true, very unfortunate, that while by the willing consent of the community the remuneration of the higher ranks of the profession had doubled or trebled during the period referred to, it should turn out that the hard-working practitioners doing duty mostly amongst the labouring classes had experienced no corresponding improvement. But as far as his information extended the leverage applied to professional remuneration from above, and this, let them observe, without any kind of pressure or trades-unionism, had, in fact, operated very generally all round, more or less, in Glasgow practice. This was the kind of answer which he would make to the remarks of the writer of the article, as regards remuneration. As to how far the profession had risen in general estimation correspondingly during these years when their remuneration had been increasing, he would not positively say, as it was a difficult and complicated matter to speak about; but most certainly as gauged by their education and general acquirements, it ought to have risen. The state of the preliminary examination of the medical profession in Glasgow, as well as in other parts of the country, was formerly very far from satisfactory. This was largely the fault of the schools, which were miserably wanting in proper provision for middle class education. In order that the profession should not fall short in point of numbers, its doors had to be opened to men who had not the education of gentlemen and who consequently had not and could not have the social status or the rank of gentlemen. In too many places the doctor in these days did not associate chiefly with the squire, or with the clergyman, but rather with the lower ranks of his patients, and from sheer want of mental resources he not unfrequently drifted into bad habits of living. The true way, therefore, to elevate the profession at large was to raise their education. This done, the fees would probably as a matter of course adjust themselves to the higher social status of practitioners. Without venturing to say that the medical profession was even now in all respects what the writer of the Article would desire or approve, it was at all events patent to everyone that a large proportion of its members in Glasgow were a vast deal better off socially than they were only a few years ago. The moral of the article was a perfectly just one. Over and over again he had told young men, that while eschewing anything in the shape of trades unionism, they ought, from the very first in their practice, to take up a good and firm position in the matter of remuneration. Let them, he had told them, say to their employers frankly, such and such were the terms on which they were willing to give their own services, and this, without any reflection, on the scale adopted and obtained by other practitioners. And the consequence was, that he had again and again known quite young men, when of good abilities and carefully trained, settling down in a district demoralised, so to speak, by a low rate of medical remuneration, and at once obtaining, almost as a matter of course, much higher fees than anything formerly paid in the district. Into the dispute, on which the article in the *Medical Times* was founded, he had no intention to enter, as it was by no means improbable that opportunities might yet occur of making a more effective stand than hitherto against a policy, which, as the Editor affirmed, could have been adopted in no other hospital or infirmary in the kingdom. To manage an essentially medical institution without regard to medical opinion was not in the face of it a very judicious or promising venture; and if the profession was only true to itself, it might be safely predicted that such an attempt must needs break down. He desired, however, on the present occasion to avoid, as far as possible, entering on controvertible matter, and would therefore with these remarks bring the Session to a close.

LIVERPOOL MEDICAL INSTITUTION

Royal College of Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners, on the 1st instant, viz.:—Messrs. Arthur F. Stace, L.S.A., Ledbury Road, W., of the Middlesex Hospital; Francis Dean, L.S.A., Albany Street, N.W., and C. R. Edwards, Antigua, W. I., of St. Bartholomew's Hospital; W. R. Puckett, L.S.A., Bath, of the London Hospital, and W. J. E. Sumpter, L.S.A., Clay-next-the-Sea, Norfolk, of University College Hospital. Six gentlemen passed in Surgery, and when qualified in Medicine will be admitted Members of the College; and six candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months; 233 candidates presented themselves for the examinations just completed, as compared with 220 at the corresponding period of last year; of this number 23 were referred to their professional studies for three months, 50 for six months, and two for nine months, making a total of 75 referred candidates. The following gentlemen passed their primary examinations in Anatomy and Physiology, at a meeting of the Board of Examiners, on the 5th instant, and when eligible will be admitted to the pass examination, viz.: — Messrs. Charles H. Melville, Ernest Roberton, Arthur R. Aldridge, Kenneth M. Scott, Caleb Terry, David D. Black, David Hume, Edmund W. Clarke, Ernest T. Roberts, Trevor J. Pritchard, Ernest B. Turner, and John R. Hill, students of the University of Edinburgh; William Calwell, of the Belfast School of Medicine; Edward L. Burd, of the Cambridge School; George M. Fox, of the Birmingham School of Medicine; John E. Stott, of the Liverpool School of Medicine; John Exley, of the Leeds School of Medicine; Francis W. Clark, of the Middlesex Hospital; and William E. Morgan, of the Aberdeen School. Four candidates were referred for three months and one for six months. The following gentlemen passed on the 6th instant, viz.:—Messrs. T. H. Griffith, H. H. Marshall, E. C. Kingdon, F. W. Collinson, A. E. Nevins, E. T. Pritchard, R. W. Smeddle, F. G. Clemow, F. T. King, and John Warnock, of the University of Edin-

burgh School; C. T. Hudson, Bristol School of Medicine; G. A. Ambler, Leeds School of Medicine; Foden Wilson, Liverpool School of Medicine; J. N. Lewis, University College Hospital; William Race, Newcastle School of Medicine; and William Downing, Birmingham School of Medicine. Eight candidates were referred for three months. The following gentlemen passed on the 7th instant, viz.:—W. H. Turton, C. C. Teacher, Arthur Wood, J. G. Glover, J. W. Smith, students of the University of Edinburgh; William Routh, of St. George's Hospital; C. H. Wild, Liverpool School of Medicine; H. S. Fremlin, Westminster Hospital; A. M. Gledden, St. Bartholomew's Hospital; Edward Posnett, Leeds School of Medicine; F. J. Lankester, St. Thomas's Hospital. Twelve candidates were referred for three months and one for six months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 1st, 1884:—

Ackland, Charles Kingsley, Bideford, N. Devon.
Des Vœux, Harold Antoine, 14, Sussex Villas, Kensington.
Hodgson, Gerald George, 52, Montpellier Road, Brighton.
Penny, Francis, Coombe, Crewkerne.
Phillips, Ernest Willmer, 75, Lansdowne Place, Brighton.

The following gentlemen also, on the same day, passed their Primary Professional Examination:—

Jackman, Charles Howard, London Hospital.
Roberts, Leonard, St. Mary's Hospital.

UNIVERSITY OF LONDON.—The following gentlemen have been elected Examiners in the Medical Faculty:—Practice of Medicine: Mr. W. H. Broadbent, M.D., and Mr. W. Miller Ord, M.D. Surgery: Sir William MacCormac, M. Ch., M.A., and Prof. John Wood, F.R.S. Anatomy: Prof. D. J. Cunningham, M.D., C.M., F.R.S. Eng., and Mr. H. Greenway Howse, M.S., M.B. Physiology: Prof. Arthur Gamgee, M.D., F.R.S., and Prof. Gerald F. Yeo, M.D. Obstetric Medicine: Mr. J. M. Duncan, M.D., LL.D., F.R.S., and Mr. John Williams, M.D. Materia Medica and Pharmaceutical Chemistry: Mr. T. Lauder Brunton, M.D., C.M., D. Sc., F.R.S., and Prof. F. T. Roberts, M.D., B. Sc. Forensic Medicine: Mr. Augustus J. Pepper, M.S., M.B., and Prof. George Vivian Poore, M.D., B.S.

UNIVERSITY COLLEGE.—The prizes will be distributed to the successful students in the Medical Faculty, by Lord Kimberley, at 3 p.m., on Wednesday, the 21st inst.

ROYAL MEDICAL BENEVOLENT COLLEGE.—The thirtieth election of Pensioners and Foundation Scholars will take place on Monday, May 26th, and the result will be announced on Thursday, May 29th. In making this statement it may be added, with that regret which will be shared by many readers of the *Medical Times and Gazette*, that for the two vacant pensionerships there are twenty-five candidates, viz., twenty-one ladies and four gentlemen, of which number only five are subscribers to this excellent institution. For the seven foundation scholarships there are just four dozen candidates; still more regretable is it to state that only six of their parents were subscribers to the College.

THE ARMY MEDICAL DEPARTMENT IN THE SOUDAN CAMPAIGN.—Sir Gerald Graham, in his detailed despatches, highly compliments Surgeon-General McDowell on his able administration of the department, and especially mentions the following officers as conspicuons for their care and attention to their important duties in the field on the occasion of the actions at El Teb and Tamai:—Surgeon-Major Wilson, principal Medical Officer of the Infantry Brigade; Surgeon-Major Connolly, principal Medical Officer, Cavalry Brigade; Surgeon Prendergast, who was badly wounded while attending a wounded man at Tamai: Surgeon-Major Catherwood, principal Medical Officer at the base, and Surgeon-Major Greene, at El Teb; Surgeon-Major Venour had charge of the sick on hospital ship at the base (Her Majesty's ship *Jumna*), and, assisted by a detachment of Army Hospital Corps, made every possible provision for the care of the wounded on their passage to Suez.

THE EDINBURGH MEDICAL SCHOOL.—SUMMER SESSION.—Nearly all the classes in the University and extra-mural Medical School were opened on the 1st instant. The classes in the University Faculty of Medicine, except those of Botany, Natural History, Clinical Medicine, and Clinical Surgery, meet now in the University new buildings.

WEST LONDON HOSPITAL.—A short course of lectures to ladies and nurses on, "The Health and the Nursing of Children," will be given at the above Hospital, by members of the Medical Staff, on the following Mondays, at five o'clock in the afternoon:—Lecture I—May 26th, "The Nursery and its Management," Dr. Venn; Lecture II—June 2nd, "Food and Feeding," Dr. Drewitt; Lecture III—June 9th, "The Care of the Eyes," Mr. Vernon; Lecture IV—June 16th, "The Care of the Teeth," Mr. Underwood; Lecture V—June 23rd, "The Early Symptoms of Illness," Dr. Hood; Lecture VI—June 30th, "Simple Remedies and their Application," Dr. Thorowgood; Lecture VII—July 7th, "Care not Over-anxiety," Dr. Goddard Rogers. The fee for admission to the entire course is 10*s.* 6*d.*

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—A *Conversazione* was held at the Charing Cross Hospital Medical School, on Thursday, the 1st instant, on the occasion of the opening of the Summer Session. The building was tastefully decorated, and there were a large number of interesting objects exhibited. The company were received by the Treasurer, Dr. Julius Pollock, and the Dean, Dr. Mitchell Bruce. Besides the members of the staff, which was well represented, a large number of guests attended the meeting amongst whom were Sir William Bowman, Sir Richard Pollock, Sir Joseph Fayrer, Sir Guyer Hunter, Mr. Campbell, M.P., Dr. Quain, and others.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—On Tuesday the Earl of Shaftesbury laid the foundation stone of the new wing of this hospital.

INTERNATIONAL HEALTH EXHIBITION LIBRARY.—In response to an invitation issued by the executive council, who have assigned large rooms to be used as a library and reading-room, in connection with the exhibition, numerous authors and publishers have already sent copies of works on subjects embraced by the two divisions of the exhibition—Health and Education. The books are being classified by Mr. Carl A. Thimm, the librarian, and a catalogue will shortly be published. As it is very desirable that the library should be rendered as complete as possible, and that the catalogue should be issued at an early date, it is hoped that those desirous of sending books, should forward them with as little delay as possible to the Librarian, Albert Hall, W.

A SATISFACTORY DECISION.—Dr. Darley, Q.C., the County Court Judge of Wicklow, recently delivered a judgment upon a claim made by Dr. Halpin, medical officer, against the Guardians of the Rathdrum Union, in that county, which will be hailed with satisfaction by the profession. Dr. Halpin had been directed by the sanitary authorities, under the Labourers' Act, to institute inquiries as to whether certain houses required to have their accommodation increased. After inspecting 22 houses he furnished his account, but the guardians declined to allow him anything for his services, alleging that, being in the receipt of a salary as medical officer, he was not entitled to make any charge. If this plea were valid, the Legislature might accumulate any work they liked upon the sanitary officer, and hold him responsible if he failed to do it. Dr. Darley, however, held a different view of professional rights, and gave a decree of 22*l.*, the full amount claimed.

HOSPITAL PROVISION FOR EPIDEMIC DISEASES IN EDINBURGH.—The work which the Corporation last year took in hand of providing a new hospital for epidemic diseases is slowly approaching completion, but a great deal remains to be done before the building will be ready for the reception of patients. Happily, it is not at present required. The surgical hospital of the Old Infirmary has been transformed into what is intended to be an epidemic hospital, with separate departments for the more distinct forms of infectious diseases—small-pox, typhus, typhoid, and measles; and the interior is being arranged and fitted up under the supervision of the Medical Officer of Health, the Health Committee, and the City Superintendent of Works. The building is a very large one, and is being admirably adapted

to all possible requirements of the city. As workmen are still employed on the building, and as the grounds have yet to be laid out, several weeks will elapse before the hospital can be said to be completed.

CALCUTTA EXHIBITION.—Messrs. Burroughs, Wellcome, & Co., have been awarded eleven medals (three gold, four silver, four bronze), and twelve diplomas of merit, for their exhibit of chemical and pharmaceutical products.

PHTHISIS IN LONDON AND DUBLIN. — Mr. Edward Spencer, who has been making some interesting statistical enquiries into the mortality of phthisis in Dublin, has come to the conclusion that children in London are born under less favourable conditions than those in Dublin, and succumb more rapidly to phthisis at the ages 0—5; that those who survive make a much harder struggle against the disease than the corresponding class in Dublin; and that, in short, consumptive people in London live much longer than those in Dublin.

THE VIENNA MEDICAL SCHOOL.—According to the "Lecture Catalogue," just published, 5,221 students were inscribed at the Vienna University during the winter session 1883-84, and of these 2,013 belonged to the medical faculty. This number of medical students has been increased by 263 for the present summer session.

"TRAUMATIC APOPLEXY" was the euphemistic verdict of a Coroner's jury as to the death of a student in Yale College, who died shortly after having been knocked down in a sparring match with one of his fellows.

APPOINTMENTS.

ALLEN, WILLIAM HAMILTON, B.A., M.B., L.R.C.S. Ire., and L.M.—Medical Officer to the Sixth District, Lincoln Union.
CAMPBELL, ARCHIBALD, M.B. and M.C. Glas.—Medical Officer to the Workhouse, Bingham Union, *vice* Charles Rowland, resigned.
CLEGG, W. T., M.R.C.S., L.R.C.P.—Assistant Surgeon to the Liverpool Hospital for Cancer and Skin Disease.
COOK, J. W., M.B., C.M. Aber.—House Surgeon to the Aberdeen Royal Infirmary.
GILBERT, HENRY, M.R.C.S., L.S.A. Lond.—Medical Officer to the Fifth District, Wolverhampton Union, *vice* John Hancox, resigned.
GREEN, CHARLES, M.D., M.R.C.S.—Medical Officer to the East Relief District, Gateshead-on-Tyne, *vice* George Douglass, M.D., resigned.
GREEN, CHARLES, M.D. Dur., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to Gateshead Eastern District, Gateshead Union.
INGLIS, A.S., M.B., C.M. Aber.—Resident Surgeon to the Aberdeen Royal Infirmary.
KNOWLES, EDWARD, M.B. and M.C. Aberdeen.—Medical Officer to the Third District, Birkenhead Union.
KNOX, CHARLES, M.R.C.S. Lond., L.S.A., L.R.C.P. and L.M. Ire.—Medical Officer to the Second District, Birkenhead Union.
LUPTON, HARRY, L.R.C.P. Lond., L.R.C.S. Eng.—Medical Officer to the Alveston District, and the Workhouse of the Stratford-on-Avon Union, *vice* John Gairdner, resigned.
MALCOLM, J.D., M.B., C.M.—Surgeon to the Out-Patient Department, Samaritan Free Hospital, *vice* Skene Keith, M.B., C.M., resigned.
MAURICE, W. J., B.A. Oxon, M.R.C.S., F.R.C.P.—Assistant Surgeon to the Royal Berks Hospital, *vice* H. G. Armstrong.
MCNEILL, JOHN BOBINSON, M.D. and M.C. Queens University, Ire. Medical Officer to the Workhouse and Schools, Birkenhead Union.
PATERSON, W. B., M.R.C.S., L.D.S.—Medical Tutor to the Dental Hospital of London, Leicester Square, W.C.
STOOKES, A., M.B., C.M., L.R.C.S.—Senior House-Surgeon to the Liverpool Children's Infirmary, *vice* G. G. Hamilton, M.B., C.M., resigned.
STURGES, O., M.D., F.R.C.P.—Physician to the Hospital for Sick Children, Great Ormond Street, *vice* Dr. Dickinson, retired.
WALLACE, WILLIAM, M.B. and M.C. Glas.—Medical Officer to Bolsover District, Chesterfield Union, *vice* J. E. Slaughter, resigned.
WRIGHT, CHARLES J., M.R.C.S. Eng.—Assistant-Surgeon to the Hospital for Women and Children at Leeds.

VACANCIES.

BUCKS COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. (*For particulars see Advertisement.*)
ELY UNION.—Medical Officer for the Downham District, in succession to Mr. F. M. Beckett, resigned. Area, 13,430 acres. Population, 2,407. Salary, £40 per annum.
NORWICH UNION.—Medical Officer to Fifth District, in succession to Mr. Thomas Thwaites Breese, resigned. Population, 16,708. Salary, £30 per annum.
GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, N.—Ophthalmic Surgeon. (*For particulars see Advertisement*).
HOSPITAL FOR SICK CHILDREN, 49, GREAT ORMOND STREET, W.C.—Assistant Physician. (*For particulars see Advertisement.*)
ROYAL SOUTH LONDON DISPENSARY, ST. GEORGE'S CROSS, LAMBETH ROAD, SURREY.—Resident Medical Officer and Dispenser. Salary £100 per annum, with furnished apartments, coals, and gas. Candidates must be doubly qualified and unmarried; they are strictly prohibited from engaging in private practice. Particulars of the duties may be obtained on personal application at the Dispensary. Applications, with testimonials of recent date to be forwarded to the Dispensary, addressed to the Committee, on or before May 12th.
SALOP INFIRMARY, SHREWSBURY.—House Surgeon. Salary £100 per annum, with board and residence. Candidates must be Fellows or Members of the Royal College of Surgeons of England, Edinburgh or Dublin, and hold a qualification to practise medicine. Testimonials, with certificates of qualifications, to be addressed to the Board of Directors, not later than May 13th.

DEATHS.

ARNOLD, JOHN, M.D., of Port of Spain, at Closebrooks, Antibes, France, on May 2nd.
BIBBY, SAMUEL HALE, M.R.C.S., at 60, Green Street, Grosvenor Square, on April 25th.
BISSILL, AUSTIN CHARLES, M.R.C.S., at sea, on board the ship *Parramatta*, on April 9th, aged 25.
CARNEGIE, JOHN, M.A., M.D., at Chesterfield, on May 4th, in his 51st year.
RICHARDSON, JAMES, L.R.C.S., at Castle Hill, near Ealing, on May 2nd, in his 68th year.
WILLIAMS, HENRY FRANCIS, M.D., Deputy Surgeon-General H.M. Indian Medical Service (retired), at Southsea, on April 27th.

NOTES, QUERIES, AND REPLIES.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

DEAR SIR,—Will you kindly insert in your next issue the enclosed copy of a letter addressed to the Honorary Secretary of the Association of Members of the Royal College of Surgeons.

I am, dear Sir, yours, &c.,
May 5th, 1884. WILLIAM HICKMAN.

To the Honorary Secretary of
The Association of Members of the Royal College of Surgeons of England.

DEAR SIR,—Will you please withdraw my name from the Association of Members of the Royal College of Surgeons of England.

When you were kind enough to urge my joining the Committee of the proposed new Association, I understood that other Fellows of the College had consented to act on it, and that the Association would be representative of the Fellows and members generally.

Under present circumstances my presence on the Committee might be misconstrued, and I should be very sorry to take up a position which could under any possibility be considered as one of antagonism to the Fellows.

I am, dear Sir, yours, &c.,
WILLIAM HICKMAN, F.R.C.S. Eng.
1, *Dorset Square, N.W.*,
May 5th, 1884.

Anatomy and Physiology.—The following were the questions submitted to the 177 candidates at the primary examinations for the diploma of Membership of the Royal College of Surgeons on the 2nd instant, when they were required to answer four and no more out of the six questions, between 1 and 3 o'clock p.m., viz.:—*Anatomy*—1. What are the distinctive characters of the male and female pelvis? 2. Give an account of the venous circulation in the cranial cavity. 3. Give the dissection required to expose the anterior surface of the brachialis anticus. Describe that muscle. 4. How would the collateral circulation be carried on after ligature of the innominate artery? 5. Describe the anatomy of the upper and lower lips. Give the attachments and nervous supply of the muscles inserted into them. 6. Give the action and nerve-supply of the muscles which move the femur on the pelvis, and state precisely the action of each muscle.

The following were the questions on *Physiology*, to be answered between 4 and 6 o'clock the same day, viz.:—1. Name the muscles concerned in ordinary inspiration. Describe the alterations in form and position of the diaphragm in respiration. How are these alterations effected? 2. Describe the fœtal circulation, and the changes which occur at birth in the course of the blood-stream. How are these changes brought about? 3. Describe the structure and uses of adipose tissue. What change does this tissue undergo in digestion when taken as food? 4. What is meant by automatic and reflex nervous action? Give examples of each. 5. Describe the physical and chemical changes which occur in striated muscle during contraction. 6. Explain the physiological meaning of the term "cell." Give examples of the different modes of cell multiplication that occur in the human body.

COMMUNICATIONS RECEIVED—

The Registrar of the University of London, London; Messrs. Nash, Stephens, & Co., London; Mr. C. Lowther Kemp, London; The Registrar of the University of Durham; Mr. Cambell, London; Mr. E. Bellamy, London; Dr. Donkin, London; Mr. Covernton, Ontario, Canada; Dr. Makuna, Pontypridd; Messrs. H. W. Carter & Co., Bristol; The Secretary of the Apothecaries' Society, London; The Librarian of the Health Exhibition, London; Dr. J. W. Langmore, London; Mr. Thomas Jones, Calcutta; The Lecturers of the West London Hospital; Dr. Galle, Ceylon; The Director of the Anthropological Institute, London; Dr. Barrs, Leeds; The Secretary of the Royal Institution, London; Mr. T. APPOINTMENTS FOR THE WEEK.

Friday, May 9 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Clinical Society of London, 8 p.m.—Mr. Clutton, "A Case of Intestinal Obstruction caused by a Diverticulum, successfully treated;" Mr. Christopher Heath, "Cases Illustrating the Treatment of Fracture of the Patella;" Dr. Whipham, "Case of Hydrocephalus of old standing, Insanity, Death;" Mr. William Anderson, "Case of Pyelo-Lithotomy;" Mr. Charters G. Symonds will show a case of "Ruptured Brachial Plexus."

Royal Institution, 8 p.m.—Prof. W. R. Smith, "Mohammedan Mahdis."

Saturday, May 10.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Royal Institution, 3 p.m.—Mr. H. M. Westropp, "Roman Archæology: The Palatine Hill."

Monday, May 12.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, May 13.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Anthropological Institute of Great Britain and Ireland, 8 p.m.—Mr. E. H. Man, "On the Ethnology of the Andoman Islands;" Prof. Flower, F.R.S., President, "Additional Observations on the Osteology of the Natives of the Andaman Islands."

Royal Medical and Chirurgical Society, 8.30 p.m.—Mr. F. J. Gant, "A Pelvic and Parietal Tumour of the Abdomen, Removal by Operation, and Recovery;" Dr. George Harley, F.R.S., "An Easy and Safe Method of Sounding for Impacted Gall-stones;" Dr. G. E. Herman, "An Average, or 'Composite,' Temperature Chart of Small-pox."

Royal Institution, 3 p.m.—Prof. Gamgee, "Nerve and Muscle."

Wednesday, May 14.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Epidemiological Society of London, 8 p.m.—Joseph Ewart, M.D., F.R.C.P., on "The Colonisation of the Sub-Himalayahs and Neilgherries, with Remarks on the Management of European Children in India." Council Meeting at 7.30 p.m.

Royal Microscopical Society, 8 p.m.—P. Herbert Carpenter, D.Sc., on "The Minute Organisation of the Nervous System of Crinoids."

Thursday, May 15.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Royal Institution, 3 p.m.—Prof. Dewar, "Flame," &c.

Friday, May 16.

Royal Institution, 8 p.m.—Prof. Odling, "The Dissolved Oxygen of Water."

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.

Physician to the Hospital.

LECTURE I.—*General Principles.*

GENTLEMEN,—When we say that to cure disease is the ideal aim of medicine, we seem to be uttering an obvious truism, and yet I have read of a distinguished French physician, who, referring to one of the horde of "irregular practitioners," observed, "*Ce n'est pas un médecin, c'est un guérisseur*,"—"He is not a physician, he is a mere curer of disease." Let us examine this seeming paradox.

At the time when medicine had no just claim to be called a science; when it was almost wholly an art, founded on a certain number of empirical rules, its *ideal aim* might no doubt be expressed in this simple fashion. But as medicine has become more and more of a science, its ideal aim has necessarily changed somewhat, and we certainly may now say that for many amongst the most distinguished of living physicians, their ideal aim is to *understand* rather than *to cure* disease. In this we see the difference between medicine as a science and medicine as an art. One aims at understanding—the other aims at *curing*. But are not these aims identical? In a large, universal sense they are; in a small, limited sense they are not. To *understand* disease would seem to be the first step towards curing it; but from the nature of things we often have to treat disease, to attempt to cure it, without understanding it in anything approaching a scientific sense, and sometimes without understanding it at all. Now there are those who appear content to deal with disease in this small way, to concern themselves exclusively with the work of encountering disease with such means as they have learned, empirically, to be useful. It is needless to say I am now only speaking of honest men in both senses. The French physician probably included amongst his "*guérisseurs*" a large class whose honesty might be questionable. But if this small view of the aim of medicine is inadequate, unprogressive, and unworthy, the larger view, if kept too exclusively before the mind, is not without its dangers. If we look back over the history of medicine during the past half century we shall notice that a remarkable change has taken place within this period, resulting from the fact that medicine has made extraordinary progress in the direction of becoming a science. In the first place the study of the several collateral and tributary branches of natural science, once closely associated with practical medicine, have become more and more separated from it.

The most learned anatomist used often to be the most

accomplished surgeon; the most renowned physiologist the most popular physician. The teaching of chemistry, botany, comparative anatomy, and histology used not to be thought incompatible with the duties of practising physicians and surgeons. But these collateral sciences have assumed such vast proportions, they have such interesting aims and ends of their own to offer to those who cultivate them, that they are now for the most part followed and taught by men who devote themselves almost exclusively to the advancement of their own branch of science.

Something of the same tendency crept into the study of pathology, and especially in so far as pathology was identified with morbid anatomy and histology, and so it happened that the ideal aim of medicine, viz., "to cure disease" became somewhat overlooked in the active prosecution of those anatomical investigations which had for *their* aim and end the "understanding of disease." The danger attending this tendency was that those who were devoting themselves with admirable energy and industry to so-called pathological studies were growing indifferent to what should be the ultimate aim of all these pursuits, viz., the cure of disease, and this tendency brought with it a scepticism as to the value of all efforts to treat disease which was irrational in itself and injurious to our influence and reputation with the public. But this period of scepticism as to the remedial treatment of disease, this period of exclusive devotion to understanding rather than curing disease, was destined, necessarily, to be of short duration. In the first place the great science of pathology could not be limited to the study of morbid anatomy and morbid histology, for it embraces the knowledge of everything that has to do with disease, and therefore is greatly concerned with the action on disease of whatever agents can be brought to bear upon it, and this is the *treatment of disease.* The treatment of disease is as much a part of pathology in its widest sense as is its morbid anatomy. Our modern pathology has been chiefly analytical; we have pushed the anatomical study of disease almost to its extreme limits, and we are now returning, richly laden with most valuable knowledge, the results of our analytical methods, to a more synthetical pathology, in which the treatment of disease is beginning to vindicate its just claim to scientific recognition, and to again be, as the outcome of all our knowledge, the ideal aim of medicine.

The introduction of the experimental method into therapeutics has contributed much towards raising this branch of medical science to its present position. We possess now a sound basis of physiological therapeutics, the area of which is daily widening, and as it extends it invades the territory of the men "*guérisseur*," and adds it to the domain of the physician because it tends to render the knowledge of disease and the curing of disease co-extensive. One word more as to the distinction between the "*guérisseur*," the curer and the "*médecin*," the physician. A rubber, a kneader, an applier of baths, of electricity; a mesmerist, a conjuror; all these may be *curers* of disease, and many of these, whether they be charlatans or not, often possess a certain skilfulness which is not without its value. But their aim does not extend beyond the cure of the particular person or persons with whom they are dealing. How different is the aim of the physician! He works not for the one, but for the many; not for the individual but for humanity; not for the present only, but for the future, for all time. For he strives to divine the secrets of Nature, and he trusts that the outcome of his life-long labours will be to leave the human race with some infirmity the less, or with some phase of disease conquered or more completely under control. And although we assert that to cure disease is the ideal aim of medicine, we also fully sympathise with him who said, "*Ce n'est pas un médecin, c'est un guérisseur.*"

I commence to-day a task which I think ought to be attempted, and one to which I am inclined by the nature of my previous studies and observations and by the natural tendency of my mind. I propose, in a series of lectures which must necessarily be a long one, though it will naturally be broken into several more or less distinct parts, to gather together and present to you, with such fitting comments and illustrations as may present themselves, the various fruits of our therapeutic researches so far as they have at present advanced.

I propose to deal fully and thoroughly with the subject of the treatment of disease as we have to deal with it clinically. The French and German literatures are much richer in works on the treatment of disease than our own; but valuable as these are, I venture to think there is an English treatment of disease which is nothing behind that of France or Germany, and it is this English method of treating disease of which I shall attempt to be the exponent.

On commencing a task of this kind, we naturally ask ourselves have we any *general principle* to guide us in the treatment of disease? Any truth of universal application? Can we practically (and all treatment is practical) speak of "disease" in a general sense and as a thing that can be considered of itself and apart from the *various* fluctuating conditions or sets of conditions which we call "diseases"? It seems to me that we cannot. The word disease is applied to conditions so widely different as well as so complex, that we can scarcely fit it with a definition. What similarity or likeness for instance can be seen between an opacity of the crystalline lens and delirium tremens? Between a vesical calculus and chorea? Between a carious bone and typhoid fever? Between an innocent fatty tumour and acute tuberculosis? Between a primary venereal sore and epilepsy? I could go on enumerating many other widely contrasted conditions, differing in their nature, differing in all their phenomena, differing in everything but this: that they all present, in a greater or less degree, deviations from normal structure (though it may only be in quantity), or disturbances of normal function, although it may only be in a small degree of activity. This is the only definition I know of, sufficiently comprehensive, to include all those conditions which come under the category of diseases. You should regard the word "disease" as merely a convenient ticket or label applied to a vast number of entirely dissimilar conditions.

Is it rational to suppose that we can arrive at any general principle of treatment, which shall be applicable in common to all these strongly contrasted conditions? I do not see how it is possible. Yet the existence of such words, the use of such words as "allopathy," and "homœopathy," indicate the survival of such a belief.

Both these terms, although they are commonly used as opposites, have this in common, that they are survivals of the pre-scientific period of medicine; they are the most conspicuous surviving representatives of dogmatic medicine.

It is the property of science to displace dogma, to present physical demonstration in the place of metaphysical speculation and hypothesis. Minds of a positive scientific turn see this, and admit it at once; minds of a metaphysical and mystical turn contest it step by step, and cling with desperate tenacity to the old, ragged garment of mystery which is rapidly falling from medicine.

There is no place for dogma in natural science, and as medicine is a branch of natural science, dogmatic medicine must necessarily become a thing of the past. It will die hard, I have no doubt, but die it must.

This being the case, is it worth our while to examine any of these dogmas? I think it is. I think it will be useful to examine one of them, in order to exhibit the exact relation of scientific medicine to it.

I am not going to argue for the purpose of converting any one; or of changing any one's belief. We learn, sometimes with much surprise, as our experience of life and of men widens, that beliefs, or what are called beliefs, are often more entirely matters of will, of temperament, or of feeling than of reason and reflection.

Do you suppose that out of 100 persons who say they *believe* in homœopathy or allopathy, for instance, there is one who has any clear conception of what he means? Who realises that it pretends to apply a general principle to the treatment of disease? That it teaches a dogma, which, if it were true, would be a sort of mysterious revelation to humanity? No doubt there are some who actually do believe this. The dogma *similia similibus curantur*, so long as it was opposed to the other dogma, *contraria contraris curantur*, was simply one error opposed to another error, one dogma to another dogma; and whoever believed in the latter dogmatically had no right to find fault with those who believed in the former. But I repeat it is the property of science to displace dogma, and scientific medicine has no dogmas.

The doctrine of similars (or the doctrine of contraries), is, as you will see, a mystic dogma, for it teaches that drugs contain a mysterious power of indicating their own uses, by producing in the healthy organism an image or semblance of the diseases they can cure!

It is pitiful to think how much time and energy have been expended over this wretched figment of the imagination. The question of dose is one entirely distinct from this dogma; whether a drug should be given in a dose of a grain or a millionth of a grain is altogether a matter of experiment.

The same may be said of the selection of drugs; and apart from their dogma, which I maintain has been altogether injurious to medical science, I believe that the homœopathists have, in many instances, called attention to the value of drugs which had been too much neglected. I might daily and hourly use every drug in their dispensatory, and in the smallest possible doses, nor should I hesitate for one moment to do so; but I should not, on that account, be a homœopathist; the only test for me in such matters, being experiment. My mind is absolutely open on such points, and free from prejudice. We must prove everything that is capable of such proof, by the laws of experimental science; that is the only test of truth in medicine that I know of.

But although I maintain that, in the nature of the case, there can be no absolutely *general* principles applicable to the treatment of disease in a general sense, it may be quite possible to find principles of partial application—principles applicable to certain groups or classes of disease. Such a principle, of which a good deal was made at one time, was that of *elimination*. It was argued that in certain diseases some of their phenomena, or symptoms, were due to an effort of the organism to throw off, or *eliminate* the *materies morbi*, the disturbing matter in the body acting as a cause of the disease, and that it was an obvious duty to endeavour to aid Nature in her attempt. For instance, in typhoid fever there is an eruption especially affecting some of the intestinal glands, which become infiltrated and swollen, and then ulcerate. This is often attended with diarrhœa, and occasionally with hæmorrhage and perforation of the bowel. This has been regarded as an attempt to *eliminate* or throw off the poison of typhoid fever by the intestinal glands, and it has been urged that, this being the case, we ought not to attempt to check the diarrhœa, but, at least, let it have its course.

Again, in acute rheumatism—one of the phenomena of that disease is a profuse secretion of acid perspiration, and this has been regarded as indicating an effort of Nature to eliminate the poison in the blood through the agency of the cutaneous glands; hence it has been regarded as useful and proper in the treatment of this disease to promote and encourage this effort at elimination.

Regard to the same principle is implied in the common practice in the treatment of the eruptive fevers, of doing nothing that can "check the eruption."

It was a belief in this principle that led at one time to the giving of purgatives in cholera.

But a very little reflection will be sufficient to show that considerable risk attends the incautious or too liberal application of this principle. In the first place it is not altogether certain that what we look upon in these instances as processes of elimination really are such. In the second place it is quite certain that in some cases, as in typhoid fever for example, if the process I have referred to as occurring in the intestinal glands is a process of elimination, that process itself may be *the* chief danger in the case, and instead of promoting the process of elimination the chief object of treatment must be to moderate or retard it.

Another principle of partial application in medicine and one which we may have unconsciously practised in many instances, is the principle of *antiseptic* treatment. This principle is founded on the germ theory of disease. Its object is to introduce into the organism substances or conditions which shall prove hostile to the life and development of the parasite upon which the disease depends. The most remarkable application of this principle is in the case of syphilis—here mercury and iodide of potassium seem hostile to the life and growth of the syphilitic fungus. The same principle probably explains the action of quinine and arsenic in intermittent fever; it has been applied also to the treatment of whooping-cough, diphtheria, phthisis, and other diseases believed to be caused by the presence of an organism or "germ" vegetating within the body. It seems not improbable that this principle may exert a very decided influence on the therapeutics of the future.

Sir Joseph Lister recently dwelt upon the important fact that the organisms which produce particular diseases are only able to develop under very special conditions, and instanced the case of the bacillus, which produces septicæmia in the house mouse, being unable to produce any injurious effect on the field mouse; which showed that the very slight difference in the blood of these two animals was sufficient to alter the conditions favourable to the development of the bacteria; and that so it was possible to conceive that, by the administration of some medicine, sufficient alteration might be produced in the blood of the human system to kill off or to prevent the development of any special bacteria on the first appearance of the symptoms of the disease in the patient.

There are, however, but very few instances in medicine of such partially applicable *principles* of treatment.

Yet there is one principle of very wide application in the treatment of disease which acts sometimes with, and frequently without, our co-operation. It is the oldest known principle in the treatment of disease that exists, being as old as disease itself. It has often been mistaken and misunderstood, and while it is itself true it has been the parent of much error and misconception. It is one which must always traverse our observations and experiences, and one which we must in no wise despise or disregard.

I allude to the influence which the mind is capable of exerting over the condition of the bodily organs. This principle of itself is equal to accounting for the

successful results which attended many of the oldest therapeutic processes, as well as some of the most modern. Amulets, charms, music, incantations, were amongst the earliest remedies for disease and pain, and these must have acted through the mind. The application of this principle to its fullest extent required an age characterised by strong religious belief in the supernatural, with little or no insight into natural science. It has less influence in an age of scepticism and positive enquiry like the present. Still, it must ever remain a potent influence in dealing with certain organisations, and to disregard it, or to neglect to avail oneself of its aid, would be as unwise, from a practical point of view, as it would have been for the Church of Rome, in dealing with certain races and classes of mankind, to have dispensed with its image worship, its music, its pictures, its incense, and all those sensuous attractions of which it has made such effective use, in order to excite and maintain the religious emotions. It was the recognition of this great principle which led to the early association of the art of healing with the priestly office. The power of influencing the physical conditions of the body, through the operations of the mind, was not likely to be overlooked by those whose aim it was to exercise an unlimited sway over human actions. We shall run considerable risk of error and confusion in our results if we neglect this important consideration—the power of grief to produce jaundice, of fright to produce chorea, of suspense to produce polyuria, and the influence of imitation in the production of disease should teach us to be ever on our guard against the disturbing influences of mental states, even in connection with those functions which seem most subservient to physical laws.

I think, then, we may safely conclude that there is no "*general* principle" universally applicable to the treatment of disease, and that there is never likely to be any. But there are many general maxims and rules partially applicable and true, in a greater or less number of instances, and these we shall become acquainted with as we advance in our course, and as the particular instances come under consideration.

The most skilful and successful treatment of disease depends on the application of the principles of common sense, resting on as full and complete a knowledge as is possible of the conditions that exist.

It is certain—I would counsel you to carry this fact in your minds—I say it is certain that the intelligent portion of the public are occasionally in advance of some of us in these common sense matters. A circumstance which arises from the fact that they have no professional prejudices, predispositions or jealousies to influence them. This is especially notable, now and then, in our manner of dealing with new remedies and new methods of treatment. At first they are ignored, then they are sneered at, then they are abused, and all manner of conflicting charges brought against them; then, after a long time, they are examined, and finally, they are accepted.

If you will look into Carlyle's "History of Frederick the Great," you will find that when Frederick visited the Low Countries at the commencement of his reign, he was attacked with quartan ague, which hung about him and tormented him for a long time. The king asked his physicians to give him quinine, which had just then been introduced as a remedy for this disease, but they "shook their heads" and gave him Pyrmont water! At last, getting no better and having important work on hand, the king—who was the incarnation of practical sense, whatever his faults may have been—insisted on having quinine, and he was immediately cured.

Now, gentlemen, that terrible "head shaking" seems to cling to our profession like an inherited vice. You see it is much easier than examination, reflection, and reasoning, and to the very simple it has the semblance of wisdom; but it is not an exercise which I should recommend you to cultivate. When you are tempted that way, let me beg of you to call to mind the great practical Prussian monarch, whose physicians, when he was shivering with his ague fit and begging for quinine, "shook their heads and recommended Pyrmont water!"

Many of our most valuable remedies have passed through this "head shaking" ordeal. The history of one of these is so instructive that it merits being mentioned here. I allude to the bromide of potassium. I need not tell you how indispensable this remedy has now proved to be—what a valuable resource it has proved in many of the most distressing nervous affections. Yet the College of Physicians introduced this drug into the "London Pharmacopœia" of 1836, and after fifteen years, during which they had the opportunity of testing its value in every possible way, in the next "Pharmacopœia" of 1851 they deemed it worthless, and omitted it from the officinal list of remedies!

There are a few not unimportant matters connected with the administration of remedies which I had better allude to now, though we shall probably have opportunities of referring to them again when we are dealing with the treatment of particular maladies. In the first place, you must be prepared to encounter very great differences in the way in which different persons and even different classes of persons are affected by the same remedy. As a general rule, the class of patients we meet with here in our hospitals are less sensitive to the action of medicines than are those whom we meet with in private practice. Many young practitioners get into trouble by forgetting this, and they are surprised to find what decided effects follow, in sensitive organisations, a dose of a drug that they have been accustomed to see given, commonly, in the hospital without any remarkable result. This is often the case with aperient substances generally. With tonics also, and especially with quinine given as a tonic. Some sensitive persons cannot bear the smallest doses of quinine when given as an ordinary tonic; and yet I have seen such persons, when attacked with low forms of disease, take a large quantity of quinine without inconvenience.

Others are intolerant of opium, a moderate dose of morphia producing alarming faintness. But I have found also, in some of these cases, the combination of ammonia with the morphia render it perfectly well borne. Indeed, there are a vast number of small but important details to be learnt in the administration of medicine, and a knowledge of them often makes all the difference between a successful and an unsuccessful practitioner.

You are aware of the remarkable sensitiveness of some patients to iodide of potassium.

Then, again, the variation in the strength of the drugs we use often embarrasses and surprises us. This is especially the case with the vegetable extracts. It is easy to understand how this may occur. The careful or careless selection of the plants from which they are made; the soil in which they have grown; the season, whether a dry or a wet one; the exact period when collected; the care in manufacture; the amount of heat employed, &c., all these circumstances may make a decided difference in the action of an important drug. I have noticed this particularly with extract of stramonium: employing the same dose, I have sometimes observed the drug to be almost inert, and at other times to have an alarming activity. Patients constantly remark on the difference in the effect of the same prescription when compounded at different places.

If you are not aware of these facts, you are liable to

deceive yourselves as to the efficacy or want of efficacy of particular remedies.

Nor is it by any means a matter of indifference in what particular form a remedy is given ; or at what particular time.

For instance, a drug, the influence of which on the constitution it is desired to obtain, but which might prove irritating or nauseating to the stomach, should be given when the stomach is full of food, and it may be enclosed in some soluble capsule or coating, or diffused through some unirritating medium.

Oil of sandal wood is very irritating to the mucous membrane of the stomach, and when incautiously given, will often set up much gastric disturbance ; but if it be diffused through liquorice powder and honey, after the manner of the Confectio Terebinthinæ of the " British Pharmacopœia," it is perfectly well borne.

It is important also to see that your remedy is not administered in an insoluble state. I have recently seen a patient who was very greatly benefited by creasote, taken in the form of pills after every meal. These pills, however, when taken for a recurrence of the symptoms, failed to have the same effect as formerly ; but on examining the evacuations, the pills were found in them unchanged ? English pharmacy has been marked by a want of intelligence, a coarseness, and an adherence to routine altogether discreditable ; and we are now, in consequence, largely using American and French pharmaceutical preparations, which our pharmacists are slowly beginning to imitate.

The time of administering medicines, with regard to food, should also be carefully attended to. Medicines which we wish should be absorbed quickly and act rapidly must not be given when the stomach is full of food, but in a stomach which is nearly or quite empty. So also with medicines which we wish to act on the gastric surface itself, as is often the case when we give bismuth or nitrate of silver.

It is obviously undesirable to give saline, or rapidly acting aperients on a full stomach ; they should be given after digestion is accomplished, so that they may only sweep away the residue of the food. Numerous other considerations of a like kind will occur to us as we advance in our course.

I hope I have said enough on this occasion to convince you that a complete examination, from a clinical point of view, of the various resources at our disposal for the treatment of disease, is a subject which demands and will richly repay your careful attention.

A CASE OF RABIES, WITH REFLECTIONS.

By L. PARKS, A.M., M.D., Harvard University, &c.

March 12th, 1884.—The subject of the following notes was a " dachshund " male, seven-and-a-half years old ; tenderly brought up, always in the same family, from the age of four months ; of an affectionate and gentle disposition ; never allowed to go at large, but in the habit of airing himself daily in a square in front of his master's residence, or in a garden ; not known ever to have even seen a rabid animal.

For several years the dog had been subject to abrasions on his back, arising from his gnawing himself there to relieve itching. This usually happened when he had been over-fed. Some four weeks previous to the above date he had such an abrasion, an inch-and-a-half square (say), which healed after being touched with nitrate of silver, and subsequently smeared with benzoated zinc ointment. Whether the abrasion in this instance was started as usual by the subject himself, or by the bite of a passing mad dog, it is impossible to ascertain.

[An unimportant uncertainty exists as to whether the item now immediately following in the record, belongs to this date or to the morning of the 13th.]

While Mr. X., the owner, was dressing, he heard his dog quarrelling with other dogs in the above-mentioned square. When dressed, Mr. X. went down to the door and drove him into the house. His dachshund, he learned, had been fighting with another dog of his own size. A large colley caught him in the act, got him down on the back, and appeared to throttle him ; the prostrate creature biting, or trying to bite back. The colley was driven off, with nose bloody, by a servant. From which of the combatants the blood came was not known. The dachshund lay motionless for a few seconds, as if dead ; then got up and attacked two other dogs on his way home, driving them off sorry. He had never before been guilty of such behaviour, though he would have an occasional tussle when " badgered " by another of his species. On entering the house he was found to have his nose bloody, and his under lip slightly abraded and swollen. He was put into a tub of warm water and washed, submitting quietly. He ate and drank as usual.

About this date he absented himself for three or four hours—a thing he had almost never done before.

March 13th.—He was let out at 3 p.m. and disappeared. [The record has now become definite as to dates.]

March 14th.—Still absent ; supposed to have been changed in temper, and to be now attracted away, as well, by some female in heat ; was advertised as lost ; was noticed by a friend of his owner to be wandering about the grounds of the barracks, not far from his home.

March 15th.—Returned, voluntarily, at 7.30 a.m., dirty, footsore, and languid ; was followed by an angry woman, who declared him mad, saying he had bitten her dog, and subsequently two others, on his way home—a short distance. A *sergent de ville*, summoned by the woman, also made his appearance, and looked at the animal ; but, in common with the owner, could find no signs of rabies. The dog drank freely ; ate bread soaked in milk reluctantly, swallowing only a few morsels after persuasion. The owner had been for some days considering the expediency of purging the animal on account of the irritable back, and took the opportunity of doing it then. Putting on thick buckskin gloves, and taking the creature between his knees, he held the jaws open while an attendant poured castor oil down the throat. He then led him to a neighbouring stable where he had him shut up in a loose box.

March 16th.—The dog was found by Mr. X. still languid, but he was pleased to go to walk. He was led by a strap a circuit of about a mile. All other dogs were driven away, but one of them slipped up behind, unawares to Mr. X., getting a savage bite on the cheek. Drinks freely, but eats nothing.

March 17th.—Dog visited in the morning—no longer languid—very demonstrative of affection. As on the day before drinks freely, but eats nothing. A woman opens the stable door a little, whereupon the dog forces his way out and rushes for home. Stops in full career to bite a nearly grown pup. On entering the house is attacked by a cat that had kittened two days previously, and gets a bad scratch on the nose which bled freely ; sends the cat off with a bitten and bloody paw ; was led back to the stable.

At 1.30 p.m. the owner, by way of precaution (having reflected somewhat seriously), takes the animal in a *fiacre* to a veterinary surgeon—Monsieur Larrouy. While doing so fancies (not knowing, however, how much to attribute to imagination) a red glare

in the eyes. Monsieur Larrouy does not like the expression of the face, but suspends his diagnosis. He chains the dog in a roomy kennel in a stable, where the solitude is broken by the frequent passage of grooms.

March 18th.—No change noted except a suspicious sound of the bark and cry. Mr. X. speaks to him through the grating of the kennel. The poor animal is delighted, thrusts out his tongue to lick, and when left cries after his master.

March 19th.—At 9 a.m. the surgeon made a *favourable report:* the dog had drunk a half-litre of water at a time, had eaten a little meat, and was quieter.

On this very day, however, a change for the worse took place. He refused to eat or drink, burying the meat given him in the straw. In the night he became violent; bit and swallowed some of his straw; bit at his chain; knawed the door of his kennel around the grating, tearing off strips of the wood; barked or cried with a sound characteristic of rabies—*cri du coq.* Towards morning of the 20th, sunk exhausted and motionless. Monsieur Larrouy found him dead.

A partial autopsy was made. The head was not opened, because the surgeon had no microscope to examine the brain with. The tongue showed three lacerations, attributed to the dog's own teeth; one of them had begun to heal. There was marked redness occupying the pharynx and the larynx, and also extending for several inches down the trachea and the œsophagus. The mucous membrane of the larynx was swollen. A straw was found in the œsophagus, showing that the subject had had the propensity, to which mad dogs are liable, to swallow non-edible substances. There were two ulcerations, each of the size of a pea, at the back of the pharynx.

The stomach had black patches, supposed to be bile, on the mucous membrane, of the size of a bean each, and several in number. The liver was greatly congested, and, I was told, a great quantity of bile escaped from it when it was cut open.

These appearances (which were shown to the writer) were said to be common in mad dogs; and, taken in connection with the history and symptoms, were the basis of an unqualified diagnosis of *rabies.*

We have here an example of the gradual manifestation of the disease, leading from mere suspicion, through uncertainty, to conviction. The police, and also all persons whose dogs were known or supposed to have been bitten by the subject of these notes, were promptly warned. The wounded cat was drowned at once. The veterinary surgeon declared that the bite of this dog was "venomous" at any time during that week preceding his death, when his behaviour was noticed to be strange; and yet the animal drank water freely up to within 24, or at most, 36 hours of the fatal event. Hence, if the veterinary surgeon's statement be correct, we derive the important lesson, that *a dog may have rabies upon him, and his bite be communicative of the disease, all the while that he is freely drinking water.*

Did the rabies arise in this dog *de novo*, or had he received a *rabid bite?*

Two or three times a year it is given out that a mad dog has been seen in this place; and the police, during some four weeks, lasso and sequester dogs going at large. Nothing of the kind had occurred for three months or more before the subject of the above notes showed his first symptoms. But this does not answer the question, as will appear from the following statement:—

The autopsy of the dog under consideration was witnessed, and the morbid appearances, with the conclusions drawn from them, corroborated by a gentleman of large experience in rabies—Mr. W. C. Standish—a former master of foxhounds in England. It was about 1864 that some of Mr. Standish's hounds became mad. They were killed. Later on, others of the pack became mad, and were killed. This process was repeated again and again, till the losses in value of dogs amounted to about one thousand pounds sterling. He informs me that "every care was taken from the commencement of the outbreak to prevent the disease spreading, the hounds being chained up in separate kennels and watched; but the disease kept showing itself up to eight, ten, and even fifteen months."

Two specimens of the infected hounds were sent to the leading veterinary surgeons of the day in London; one specimen being of the violent kind, the other showing the "dumb-madness," so-called. They were both pronounced indubitable cases of the disease.

A question was put by Mr. Standish as to how long a time must elapse, after a rabid bite, before a dog, showing none of the symptoms, might be considered safe from its effects? The answer of the authorities on canine affections was "eight months." Now Mr. Standish isolated one of his hounds that had been bitten by another that was rabid, and kept the former *fifteen months*, at the end of which time the animal under observation went *mad.*

I may mention, by way of parenthesis, that some time subsequently to the events just mentioned, the friend of another master of fox hounds, at a distance, wrote to Mr. Standish that rabies had got into the pack, and asked advice as to what he had best do. Mr. Standish replied that it would prove the cheapest in the long run to exterminate the whole of them at once, even if the proprietor had to purchase anew. The pack was accordingly destroyed, but it was replaced by gratuitous contributions from different packs—five from this—ten from that—and so on; Mr. Standish, at whose instance the general contribution was made, furnishing his quota.

To resume. The above facts warrant the following inferences, viz.: First, it is within the bounds of possibility that Mr. X's dog had been bitten by a mad animal *as much as fifteen months* previously to the outbreak of the symptoms in the former; and, therefore, the question whether the disease had arisen *de novo* in this case is transferred into the region of conjecture. Secondly, the most obvious way to stamp out rabies from an infected district—short of general extermination—would be a regulation strictly enforced, and continued, without interruption, for a long period, to impound all dogs not *effectually* muzzled, when away from home, and whether led or not. At short intervals, the animals thus impounded, if not properly taken charge of by their owners, might as well be destroyed. As to what precise limit of time should be applied to this regulation, the writer has not as yet formed an opinion, except that it should not be less than *fifteen months* (the incubation of hydrophobia in man being sometimes much longer than that). Thirdly, we should be chary of handling dogs at all indisposed (even though they do not refuse to drink) until the nature of their disorder be fully declared. Finally, the case above reported illustrates an important maxim—avoid killing a dog suspected of madness until the diagnosis is clearly made out. Isolate him! If, then, he prove to be mad, your warnings to those whose animals may have been bitten by him, will carry force; and, moreover, will shift the responsibility upon those owners. If, on the other hand, the peculiarities which have brought your dog into suspicion should, happily, develop into some other form than rabies, or subside, all apprehensions of his having transmitted such a terrible disease to man or beast are completely set at rest.

It would seem unnecessary to add that every dog, or other brute, that has been bitten by a rabid animal should (unless carefully isolated for purpose of

experiment) be immediately put to death, before he has a chance of contaminating others, and that on the score of both principle and prudence. Yet, strange to say, this precaution is not always taken.

Pau, France, May 5, 1884.

AN EXAMINATION OF THE THEORY OF AËRIAL DISSEMINATION OF SMALL-POX INFECTION.

By MONTAGUE D. MAKUNA,
Late Medical Superintendent of Fulham Small-pox Hospital.

The object of this paper is to demonstrate how the infection of small-pox is disseminated by ordinary channels, and thus prove that the theory of aërial dissemination of small-pox infection at long distances, as enunciated by Mr. W. H. Power, of the Local Government Board, in his Report "On the influence of Fulham Small-pox Hospital on the neighbourhood surrounding it," is purely speculative. He conducted his investigations in January, February, and March, 1881, and because he could not ascertain the sources of infection of cases in the districts of Kensington, Fulham, and Chelsea, he started this theory, and by an elaborate series of tables he has tried to make it applicable to the years 1877, 1878, 1879 and 1880. The following history that I have collected during these years will prove that his data are erroneous, inasmuch as he has not known the facts and history of the local outbreaks of the disease, the mismanagement of the institution, overcrowding, and other conditions of the population in the locality. In the parish of Fulham, according to the Census of 1871, there were 4·9 persons to a house; while, according to 1881, there are 7·3. Nearly all the houses in Fulham, within half a mile of the hospital, are of recent growth, and inhabited by labouring and artizan classes, migrating from the country and from parish to parish, according to the activity of trade and agriculture, extension of railway works and manufactures in the locality. They come, unguarded by vaccination or re-vaccination, live for a short time in infected haunts, and thus fall a prey to the unknown foe. In West Brompton, within half a mile of the hospital, the building operations have also been active. The houses in Adrian Terrace and Ifield Road (it is one long street, and both the names are used indiscriminately), where the disease has been most prevalent, built for a superior class, have come to be occupied by the artizan and labouring classes. These streets are overcrowded, the intercommunication between the houses is very free, and the population ever changing. They form the borderland of the central circle of Mr. Power's "special area." Higher up are houses in Coleherne Road, Westgate Terrace, Redcliffe Gardens and Square, and the turnings through them, Tregunter Road, Cathcart Road, and Fawcett Street. Still higher up are the Boltons and Onslow Gardens. On leaving the area of the central circle, we find the houses are occupied by superior classes, and in the area between half to one mile distant from the hospital some of the highest and noblest live. When cases of small-pox do occur in their houses, they are chiefly among servants who have in considerable numbers contracted it by visiting their friends in haunts of infection. It would be monstrous to draw calculations from these houses, the number of which increases the further we go from the hospital, and consequently gives a higher average on the poorer houses in Chelsea and Fulham in the same "special area round the hospital," and thus add an argument to the speculation that the vitality of the infection diminishes the further we recede from the hospital. There are no houses within a quarter-mile of the hospital in Chelsea. Beyond this are those in Fulham Road, King's Road, Church Street, and intersecting streets. These main streets, especially Fulham Road, which is a boundary line between Kensington and Chelsea, are composed of shops. The people in West Brompton, especially the poorer classes, deal with these shops. Had one cared to investigate the prevalence of the disease in these shop-houses in Chelsea, where there was no isolation of the sick, and everybody went in and out unguarded, sufficient cause of infection would have been found. There are numerous small laundries in Chelsea where infected clothing was washed; the workers took small-pox and continued at their occupation. Chelsea is notorious for infected haunts, and its old houses are quite unlike the mansions in Brompton, or the cottages in Fulham. All who know the different characteristics of Mr. Power's "special area" will bear me witness when I say that to draw averages on houses in this area, counting them as so many units, is like buying and selling books by weight. It would be an egregious blunder to lose sight of these facts and circumstances in investigating the origin and spread of an epidemic disease midst such a mixed population. An epidemic disease, when once introduced among the poorer classes, becomes endemic, gives rise to so-called sporadic cases, which, under favourable circumstances, lead to fresh outbreaks of epidemics time after time. Again, infection, unless it is directly attacked, retains its vitality for propagation for years, and harbours in nooks and corners, adhering to many household articles, furniture, clothing, &c., with a tenacity scarcely conceivable, but which has been repeatedly demonstrated by investigators in all parts of the world. The most systematic and scientific disinfection, and renewing of hospital wards, ships, barracks, huts, houses, and their belongings, have been futile in many cases. Bearing this fact in my mind, I for one cannot realise the idea that the dwellings of the poor of London can be thoroughly disinfected after the occurrence of infectious cases as is done at the present day by the local sanitary authorities. When I was at Fulham Hospital I noted the fact of cases occurring in the same house time after time, and year after year, the fresh victims in many cases being quite unaware of the previous cases.

Small-pox is, socially speaking, a misfortune, because no sooner is its existence in a house known than its inmates are thrown out of employment and shopkeepers lose their trade. Under these circumstances, concealment of cases, even among well-to-do classes, is frequent, if not discouraged as it should be by medical men, is connived by authorities among their friends and the death certificates falsified. We know more of these practices in poorer localities, because their means of isolation and concealment are few, their methods of evading all enquiry less refined, and through many causes the tendency of the disease to spread among their class more general. I have known many well-to-do people leave town to shake off infection and the houses either changed altogether or renewed. Their servants, as a rule, being not re-vaccinated, take the disease, and are either sent home ill or removed to the hospital.

I have sometimes found that when all the efforts of the sanitary authorities to get at the sources of infection were baffled through the disingenuity of the people, the truth was revealed to me through children in the hospital on the offer of small enticements. Add to this concealment of cases or facts bearing on the primary cases, the numerous cases of varioloid among the vaccinated adults at work and children at school,

besides the treatment of such cases in public dispensaries and out-door departments of hospitals for other affections, and we need not have recourse to hypothesis to account for the mischief. Taking all these and many other circumstances into consideration, I contend that the infection of small-pox in certain localities in London is ever existent, a thorough and systematic disinfection has been rendered impracticable, and the explanation of its spread through air is a confession of our inability to cope with the disease, and of our iguorance of its immediate sources. I do not deny the dissemination of contagion through air, the very word *infection* means it, but it is difficult to conceive atmosphere as a mere carrier of infection at long distances. Have heat, light, moisture, ozone, and other constituents of the air no influence on the economy of animal and vegetable life?

The conditions that favour the spread of small-pox are the absence of re-vaccination among adults, non-vaccination at all ages, overcrowding, malnutrition of the body, accumulation of filth in clothing and linen, defective sanitation in houses, free intercourse among houses and families, children playing together in streets. All these causes abound among poor people. With these facts before me I have felt surprised, not because I have not been able to account for the cases that came to my knowledge, but because of the repeated escapes of so many people in an infected locality. Mr. Power began his enquiry nearly four years after the establishment of Fulham Hospital, surrounded by such a locality, and his Report gives us no idea of the condition of the houses in the *special area* forming a circle round the hospital within the radius of a mile, which includes many magnificent and palatial residences in Brompton as well as wretched hovels in Fulham, and old and inferior houses in Chelsea, upon which he calculates averages, taking houses as so many units, irrespective of all other conditions, to support his dazzling theory. It was not possible that he could study the locality in a few weeks. Had he confined himself to the explanation of a few cases he enquired into I should not have felt it necessary to criticise his Report. But by the addition of a series of tables and maps, professing to explain the outbreaks of the disease in previous years by mere calculations and averages, he has tried to harmonise facts in a manner contrary to my experience as the Medical Officer of the Fulham Small-pox Hospital.

With this introduction, I shall narrate the history of the hospital, and the incidence of the disease in Kensington, Fulham, and Chelsea. For the sake of convenience I shall adopt the same terms used by Mr. Power for defining several areas.

Special Area (S. A.,) means the area included in a circle with a mile radius, having the hospital for its centre.

Outside Special Area (O. S. A.,) area beyond the special area.

Central Circle (C. C.,) means the area included in a circle with quarter mile radius, with the hospital for its centre.

Half Mile Ring (½ mile R.,) means the area between the central circle and a circle described, with a half mile radius.

Three Quarter Mile Ring (¾ mile R.,) means the area between ½ mile R. and a circle described with three quarter mile radius.

One Mile Ring (1 mile R.,) means the area between ¾ mile R., and a circle described with one mile radius.

Small-pox became epidemic in London in the summer of 1876, when the Stockwell Small-pox Hospital was the only one available for the metropolis. Very soon Homerton was opened, and it was followed in the November of the same year by Hampstead. In March, 1877, Deptford and Fulham Hospitals were established. Hence it becomes necessary to know whether small-pox was existent in the locality before the opening of the Fulham Hospital, on the 10th of March, 1877. We find from the returns of the Metropolitan Asylums Board, that there were 31 admissions from Fulham, 50 from Chelsea, and 115 from Kensington at other small-pox hospitals up to the latter date. During the same period the Highgate Small-pox Hospital had admitted 24 from Kensington, of which seven were from Brompton, 30 from Fulham Union, of which fourteen were from Fulham Parish, and eight from Chelsea. During the year 1876, there were 736 deaths from small-pox in London, of which ten were in Kensington, three in Fulham, and four in Chelsea, while the Metropolitan Asylums Board Hospitals had admitted 2,120 cases of small-pox. This conclusively proves that the admissions to these institutions does not mean incidence of the disease in the metropolis. A death certificate sometimes reveals an outbreak in a locality of which the sanitary authorities had no knowledge. Many mild cases are treated, as cases of chicken-pox, measles, skin affections, &c. Dr. Dudfield informs us, in his annual report for 1876, that during the year there were about 30 cases treated at home in Kensington. He had traced the spread of the disease through laundries, and among the victims were several ironers, manglers, and laundresses. Another feature noticed by him was, that in Brompton the victims were mostly adults, many being domestics, while in the Kensington Town Sub-district they were of all ages. The same peculiarities had been recorded by him in the epidemic of 1871–72, and they go to prove that the sources of infection in Brompton must be outside the district. On my visits to the locality in January and February, 1877, I was informed of nearly a dozen cases of small-pox in the Central Circle and ½ mile Ring. It is evident, therefore, that the sources of infection were rapidly multiplying in the locality, and especially in the small shop-houses and laundries, with the rise of the epidemic in the metropolis before the hospital was opened.

The Fulham Small-pox Hospital was opened on March 10th, 1877, and during the first week it received convalescents, and during the second week some acute cases, the admissions being confined to males over 7 years of age. The children and females were either treated at home or taken to other hospitals. This arrangement was unavoidable, and it would have been well had the managers not opened this hospital in its then incomplete state, and thus saved one blot on the management. The southern wing, with five wards, was barely ready to receive patients. The administrative block and the northern wing were fenced off to prevent the workmen and patients mixing together. Some workmen were re-vaccinated and were engaged to finish the kitchen and laundry, which were also incomplete. A room to keep disinfected clothing had been forgotten; a wooden shed with venetian walls was soon erected as a substitute. The disinfecting chamber was put up in the engineer's workshop, as no provision was made for it. The mortuary was not ready for months, and coffins were first used to remove the dead bodies from the wards, and piled up one on the other in the room. Out of the five wards of the southern wing, one was used as a store-room and mess-room for male attendants, and another as their dormitory. The medical officer, assistant medical officer, and the steward had each a ward scullery for their residence, offices, and dispensary. The attendants were males and their wives. Some of them slept outside with their families, and had their lodgings generally in Walham Green. Most of the workers in the kitchen and laundry slept outside. The washing of the staff was sent out for weeks, while the patients' clothing and bed linen were left to accumulate for days, in

expectation of the completion of the laundry. A porter's lodge had not yet been provided, and a temporary gate was put up nearest the southern wing by breaking through the boundary wall. The reception-room was used as the gate porter's lodging-room, admission and discharge room for the patients. The non-resident staff left in the evening, to return in the morning. The resident went out every evening, and half-day once a week. Cases of small-pox occurred in their families and among their friends. They were either treated at home or sent to hospitals. The administrative block and northern wing were ready in May. The former building was unfit for its purpose, as it was wanting in rooms of every description. There was no provision for a dispensary: it was fitted up in a small corner room. There was no bath-room for superior officers, and only one bath for the rest of the staff, both males and females. There was no provision for the assistant medical officer. The steward was expected to reside outside. There was no coal-cellar for the whole of the block, excepting one for the apparatus for hot-water pipes. Only one scullery for the whole block. The washing of plates, &c., was all done in the kitchen. The sleeping accommodation for the staff was insufficient. Now and then two girls have slept in one bed, and in rooms too small for one. Two wards had to be used as dormitories, one for the males and the other for the females. There was no adequate provision to keep sexes among servants separate, and all manner of dereliction of duties had to be excused. The rooms were all poorly and badly furnished. The surface drainage, roads, and paths in the grounds were left unfinished by the contractors, and the passengers and ambulances had to wade through mud and stones. The firegrates and scullery fittings of the wards were condemned before they were used, and had to be gradually replaced and deficiencies gradually supplied. The washing of the staff was at first done with that of the patients, and after many remonstrances a sort of a separate provision was made. The drying horses were few, and a portion of the grounds was set apart with wooden poles and iron cords to dry washed clothing and linen in the open air. The walls of the wards and the rooms in the administrative block were left bare and dirty, as workmen left them, without paper, paint, or limewash, till the year 1880. The porter's lodge was not ready, and the proper gate was not in use till about the middle of the year 1879. Many parcels and presents for the patients were brought in by the traders' carts, nurses, &c., who visited the patients' friends at home, and I had to exert a most rigid supervision to keep many improper things out of the wards. The nurses did their knitting and sewing in the wards, and carried the work outside in handbags, which were every now and then turned out of wards by me. Although they changed their dresses when going out, they always passed along the corridors, and sometimes spent hours in out-door garments in the ward sculleries and receiving-rooms when tired of walking the streets. They had no kind of recreation or sitting-room except the mess-room, which was also their pantry. Reports, reprimands, discharges of servants, did them no good, and the institution every now and then lost a good servant. Numerous complaints of the spread of the disease from the hospital were made, and they were explained away in one way or another. If the complaint was that the members of the staff slept outside, they would reduce the staff and adopt some means for a time to report that no one slept outside. If the complaint was that the refuse of food caused the spread, they would stop it and report none left the premises. If the complaint was that poultices, rags, &c., that went out of wards with the dust, caused the disease, they would issue an order to burn them and report it as such. When cases of small-pox occurred amongst friends and relations of the staff, they would suddenly disappear before they came to light or could be investigated. Many patients, and male and female servants married away from the hospital.

In the Hampstead Hospital trial it was proved in court that the hospital was mismanaged as far as the safety of the public outside was concerned. Had they taken advantage of their experience, done away with many abuses, and investigated the local outbreaks, there would not have been any necessity for Mr. Power's Report, nor for pleading through a Royal Commission for their errors, nor for a compromise with the opposite party at the expense of the public purse, and acceptance of the dogma of aërial infection. Had these allegations of mine been known and considered by Mr. Power, he would not have been led astray. Let me ask those who adopt the theory of aërial infection, whether we are to forget all the foregoing facts which point to so many ways of the spread, and for a while roam in the region of fancy and philosophy to search after something new to pacify the public mind?

I shall now make a detailed statement of the incidence of the locality in Kensington, Chelsea, and Fulham for the years 1877, 1878, 1879 and 1880, which will show that Mr. Power's figures of the incidence are inaccurate, and his method of counting of houses in the circles and rings of the special area misleading.

(*To be continued.*)

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

CANCRUM ORIS—SPREAD OF THE DISEASE—ABSENCE OF MICRO-ORGANISMS IN THE BLOOD—DEATH—AUTOPSY.

(Under the care of Mr. CHRISTOPHER HEATH.)

(We are indebted to Mr. VICTOR HORSLEY, B.S., F.R.C.S., for these notes.)

CHARLES L., aged 12 years, was admitted into the hospital on January 31st. He had first noticed a blackish lump on the right side of the mouth, close to the bicuspid tooth a week ago. This has gradually spread. He has had a disagreeable taste in his mouth, and the odour from the lump has been very fetid. Four days ago he went to see a medical man. He has no idea what started the disease.

On admission, the gum on the right side of the lower jaw was spongy and ulcerated, and opposite the first molar it was gangrenous, and covered with a greyish slough, more extensive on the inner than the outer side of the gum; it did not extend beyond the reflection of the mucous membrane from the jaw, on to the tongue: several of the teeth were loose, and painful when pressed upon. Strong nitric acid was applied, the patient being under chloroform.

February 1st.—The cauterised part had assumed a brownish-yellow colour, with very little redness or swelling around: early in the day there was little or no pain, but towards evening pain came on, and opium had to be given internally, while glycerine and belladonna were applied externally.

February 2nd.—The lower lip was swollen, and the gum about the incisor teeth dark red, and covered with

a greyish slough: the tongue remained healthy. The glands, both in front of and behind the sterno-mastoid muscles, very tender.

By February 7th, the ulcer had extended considerably; it was in a sloughy condition, and its base very tender. The under-surface of the tongue and the mucous membrane of the cheek were now implicated. The cervical glands much swollen and very tender; the temperature ranges between 101° and 103·8° F. He was fed with a tube. Mr. Heath had the patient put under chloroform in the afternoon, and carefully scraped the surface of the ulcer with a sharp spoon, and then applied the actual cautery, the mouth being afterwards washed out with glycerine and carbolic solution.

On February 10th, the sloughing was found to be again extending; he had had his mouth swabbed out at intervals with glycerine of carbolic acid, and had used a gargle of chlorate of potash. There was noticed yesterday a copper-coloured papular rash on both buttocks, and on the lower part of the legs. His chest was carefully examined, but beyond a little rhonchus, nothing abnormal was found.

February 12th.—The sloughing in the mouth was extending, his tongue was raised, and pushed backwards and upwards, and was rather swollen.

February 15th.—The boy begins to be very anæmic. His blood was examined for organisms; but none were found. On counting the corpuscles there seemed to be a diminution in the number, both of the white and the red.

February 16th.—Condition remained about the same. The blood was again examined; there was an excess of white corpuscles, many of which were undergoing fatty degeneration; some of the red discs were breaking down; the blood when fresh drawn had a thin watery appearance; there were still no organisms.

February 18th.—The patient passed a restless night; he was constantly crying out, refused nourishment; now he lies in a semi-conscious condition, very much exhausted. The lips are covered with dark sordes. The blood is still more watery in appearance, and coagulates feebly. In ten squares of the hæmocytometer there were only forty-five red and eight white corpuscles. Under the microscope, no organisms were detected; the white corpuscles appeared larger than normal, some showed amœboid movements, and some granular fatty degeneration. Death.

Autopsy by Mr. Horsley:—The skin is dusky; rash has disappeared; there is a hard thickening on the right side, extending from the angle to just beyond the symphysis of the lower jaw. On cutting through the tissues in front of the neck, they are found to be œdematous as low as the upper third of the pectoralis major muscle. The gangrene has reached the corium at a point opposite the middle of the body of the lower jaw. On reflecting the skin, the right cheek is found to be destroyed for its anterior and lower half. The buccinator muscle is converted into a foul, dark grey slough, the fat covering it is infiltrated and œdematous, and is hard on section; it, however, still preserves its yellow-white appearance. This infiltration of the fat extends for about one inch beyond the margin of the slough. On exposing the jaw, the right half is found to be bared as far as the tip of the coronoid process, the attachment of the temporal muscle separating from it, owing to the suppuration, which has reached back to the pterygoid region. Posteriorly, the limit of exposed bone corresponds to the line of attachment of the masseter and internal pterygoid muscles respectively. Below, it reaches to the lower border of the body both in front and behind. The whole of the alveolar border is blackened, more especially along the canine and incisor sockets. The mucous membrane, where ulcerated, is covered with a greyish-yellow slough, and is sharply marked off from the remainder by a hyperæmic line of demarcation. The sloughing process extends into the base of the tongue, destroying the frænum, forming a polypoid mass of granulations and slough; and forcing the tongue upwards and backwards. The rest of the mucous membrane of the mouth appears to be perfectly healthy; the œdema which is noticed as extending in front of the hyperæmic border in the loose connective tissues of the cheek is absent from the mucous membrane of the mouth. The lymphatic glands on both sides of the neck are enlarged, but more especially on the right side, some portions appearing intensely congested, others, especially the medullary portion, of a pale white colour.

The pleuræ contain about three ounces each of pale straw-coloured serum, which coagulates into a firm jelly on the addition of blood; there are a few petechiæ on the right side. The peritonæum is apparently normal. Parietal pericardium shows a few petechiæ The heart cavities contain a small quantity of fluid blood. The visceral layer of the pericardium on the anterior surface of the right ventricle shows a mass of petechiæ along the distribution of the left coronary artery: a similar condition is found on the posterior surface. The endocardium is rather bloodstained: a few petechiæ are found on the septum. The petechiæ in places extend into the muscular substance for a distance of about 3 mm. The heart muscle is everywhere pale, but preserves its normal density. Valves all healthy; aorta healthy. Lungs: Right. The outer and under surface of the upper lobe is covered with recent lymph, and there are small patches scattered about elsewhere: there are also a few petechiæ here and there. The bronchial mucous membrane is perfectly normal, except in one branch in the upper lobe, where it is congested in places. The upper lobe is œdematous, airless, and of a dark red colour, showing on section broncho-pneumonic patches; middle lobe presents small areas here and there of congestion, is otherwise normal; lower lobe slightly congested; left lung much in the same condition; none of these congested areas are more than 3 mm. in diameter; liver is normal in shape, but increased in size; it has a homogeneous, ground-glass appearance; bile ducts are distended. The spleen is slightly enlarged, but not otherwise markedly changed. Intestines: In the cæcum there are two small ulcers, each surrounded by a hyperæmic border. The right kidney presents a few petechiæ beneath the capsule; the organ on section is pale and bloodless; left kidney on section is found in the whole of its depth, to be of a pale yellowish-white colour, surrounded by a congested border; both kidneys are normal in size: nothing noteworthy in the intestines, or bladder, or pancreas. On the under surface of the dura mater, covering the posterior half of the left inferior frontal convolution, and the lower half of the fissure of Rolando, there is an effusion of blood, and beneath this, the whole of this side of the vertex is sprinkled over with numerous hæmorrhages, especially along the line of the intra-parietal sulcus. These hæmorrhages run in the line of the cerebral veins. On the right side there is a similar patch of hæmorrhage over the posterior half of the middle frontal convolution; the rest of the dura mater covering the vertex is similarly sprinkled with small hæmorrhages. The arachnoid and pia mater are infiltrated and œdematous, and there are also scattered about small hæmorrhages.

Remarks by Mr. Victor Horsley:—In the foregoing case there are two points of interest. (1) The continuance of the disease, and (2) the immediate cause of death. As for the first it may be fairly assumed, in view of the most recent observations of the necrosis of tissues following the growth of organisms in the same, that the cauterising agents failed to reach the foci of

development of the parasite, and that the disease simply spread unchecked. Microscopically, however, the spreading border of the gangrene simply exhibits œdema, and infiltration of the loose tissues with leucocytes, and I have only been able to demonstrate the existence of bacterium termo in those parts which were putrid during life. (The *post-mortem* was performed within half-an-hour after death, and the tissues were put into absolute alcohol.) As negative evidence this fact is of course worth very little, and it is only mentioned here in the hope that other cases will be examined in the same direction.

The cause of death appears to have been a simple case of sapræmia, the excessively foul condition of the ulcerated mouth affording constant and large supplies of sepsin, which was swallowed by the patient in considerable quantity, even soon after his admission. The certain absence of organisms in the blood during life, and the whole *post-mortem* appearances point in the same direction. In connection with the latter it must be remarked that the ulceration of the cæcum is a very slight representative lesion, when the results of experimental sapræmia are remembered.

Medical Times and Gazette.

SATURDAY, MAY 17, 1884.

At the meeting of the Ophthalmological Society on Thursday se'nnight, a good deal of business was done. There were not so many patients as we have sometimes seen, but there were some very good drawings on view. Amongst them were two of Mr. Nettleship's, one of central guttate choroiditis, the other of peculiar lines in the choroid, the exact interpretation of which might be open to some doubt. Mr. Morton showed a drawing of a hæmorrhage at the macula, dependent on gout, the chief interest being the shape of the hæmorrhage, Mr. Milles recorded a nævus of the choroid, which, we believe, has not hitherto been subjected to the proof of a microscopical examination. Dr. Stephen Mackenzie added another to his list of cases of tortuous vessels in the retina.

Dr. Fitzgerald described some cases of acute spasm of accommodation, and Mr. Higgens summed up his experiences in the operation for extraction of cataract on 200 cases, since his paper on the same subject was read a few years ago at the Royal Medical and Chirurgical Society. The paper which attracted most interest, however, was the joint production of Dr. James Anderson and Mr. Gunn, on a case of alleged uniocular diplopia. The paper itself deserves the highest praise, for it was very thoughtful and thoroughly impartial. As to the general question whether such a disorder can be *bonâ-fide*, we shall probably express the opinions of the majority when we say that the natural attitude of ninety-nine men out of a hundred would be one of absolute incredulity. We think, however, that it is only fair to the authors of this paper and of previous communications on this subject to the Society, that so active a form of disbelief should be exchanged for some more passive scepticism. The affection has not yet proved its right to official recognition, but is quite entitled to claim a fair hearing.

The relative merits of the various modes of treating fractured patella were once more discussed at the meeting of the Clinical Society, on Friday last. True to a pledge which he had given at a meeting of the Society six months ago, Mr. Christopher Heath produced for inspection a case which he had then treated by the immediate application of a plaster of Paris bandage. Mr. Henry Morris, who had been called upon to treat a case upon the same day, also produced his patient. In both cases firm fibrous union had taken place, and in both, the patients had been able to walk freely with artificial support to the knee-joints. These results, admirable as they are at the present time, can hardly be reckoned upon as the ultimate outcome of the treatment. The experience of all surgeons would seem to agree that some further separation of the fragments is sure to follow upon fibrous union, as soon as artificial support is dispensed with, and hence no close union, other than that by true bone, can be looked upon as a permanent condition. True bony union, however, is only to be obtained by means of the operation of wiring, and a very general opinion seems to prevail that this operation is at present only justifiable in very skilful hands, as, *e.g.*, in those of its originator, Sir Joseph Lister. (In another column we have given an account of some foreign views with regard to the treatment of this accident.)

A case of abdominal section, undertaken for the relief of internal strangulation of bowel, was read by Mr. H. H. Clutton. The author was deservedly congratulated, not only upon its triumphantly successful issue, but upon the skill displayed in dealing with a case of extreme difficulty. With each successive victory over the dangers attendant upon intra-abdominal surgery, confidence becomes proportionately increased, and we would cordially re-echo the hope expressed by many of the speakers in the subsequent debate, that operations for the relief of internal herniæ may be placed upon a similar footing to those for the commoner forms of external rupture. To delay an inevitable operation, when the benefit of the doubt is so rarely found to be a benefit to the patient, seems somewhat irrational, and has long since been abandoned in the simpler class of cases.

An interesting case of old-standing hydrocephalus, leading to insanity and death, was read by Dr. Whipham, and two remarkable cases of rupture of the brachial plexus were exhibited by Mr. C. J. Symonds. Towards the close of the meeting attention was called by the President to the number of papers still remaining unread on the eve of the last meeting of the session. No definite expression of opinion was elicited on his proposal to hold an additional meeting, and the question will be decided at the next meeting, on May 23rd. This practice and that of indefinitely extending the time of individual meetings, is one which has

grown of late in other societies, as well as in that presided over by Sir Andrew Clark. The appetite for work displayed by the attendant members is in the highest degree satisfactory; but the custom is in itself unbusiness-like and inconvenient, and is one which we believe but few members are willing to see extended.

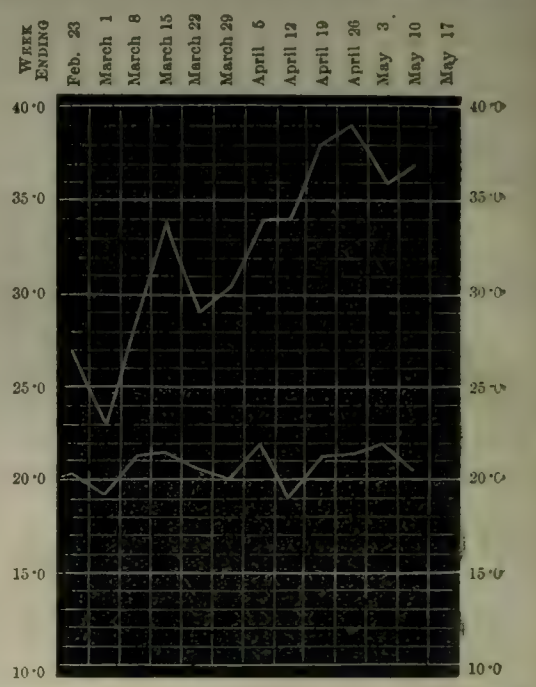
At the meeting of the Royal Medical and Chirurgical Society on Tuesday last, two papers were read. That by Mr. Gant, on the removal of a pelvic tumour, not offering much scope for discussion, was soon disposed of. The paper by Dr. George Harley, on an easy and safe method of sounding for impacted gall-stones, was, however, vigorously discussed. The boldness and originality of Dr. Harley's procedure were admitted, but it was pointed out that the argument that most organs of the body have been punctured with a fine exploring needle without ill result, is not a very strong one in favour of a further application of this practice.

The third General Meeting of The Hospitals Association will be held at No. 11, Chandos Street, Cavendish Square, W., on Wednesday, the 21st May, 1884, at 8 p.m., when Mr. Henry C. Burdett will read a paper entitled, "How can the Hospital Sunday and Saturday Funds be made more useful to the Hospitals?"

We may hope that the action of Friday last will be allowed to close the series of persecutions to which Messrs. Bower and Keates have been subjected. The issue was as satisfactory to the defendants as, under the circumstances, it could be, and that without the necessity for placing in the witness-box several eminent medical authorities who were ready to give evidence for the defence. Some compassion may be extended to the father of the dead child, who has evidently become a prey to the haschisch of litigation, and is bent on running a-muck, regardless of consequences to himself. It is to be hoped, however, that his career in the law courts will at length be checked, or at any rate that his attacks may be directed in another quarter. Messrs. Bower and Keates have been sufferers without a parallel in the history of medical prosecutions.

The Inaugural Dinner of the Oxford Graduates Medical Club will take place on Thursday, 22nd inst., at 7 p.m. The chair will be taken by Dr. Fincham, and a large gathering is expected. It is hoped that any gentlemen who have not received notices of the Club's formation, will at once communicate with the Secretaries, Dr. Samuel West, or Mr. John H. Morgan.

The most significant fact in the Registrar General's weekly return is the increase of the small-pox epidemic. During the week the number of cases in hospital rose from 502 to 737, and the fatal cases numbered nineteen. We are evidently in for a considerable epidemic. The number of deaths from other zymotic diseases still continued high, viz., 264, or 57 above the ten years' average. The chief culprits were still measles and whooping cough, which represented respectively a mortality of 93 and 119. In spite of the excessive number



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of last quarter, and the first six weeks of the present quarter.

of zymotic fatalities, the general death-rate fell to 20·6 per 1,000, having been, as may be seen from the chart, 22 in the preceding week. The deaths from respiratory diseases, viz., 326, were six below the average, and 32 below the previous return.

The return of Dr. Koch and his fellow-labourers, Dr. Gaffky and Dr. Fischer has been celebrated during the past week in Berlin with the enthusiasm which their recent labours in Egypt and India so fully justify. Whatever be the ultimate result of their researches upon the progress of cholera in either country, there can be but one opinion amongst all scientific workers in the four quarters of the globe as to the vigour, perseverance, and honesty of purpose which have characterised their endeavours to unravel the tangled skein of causes which combine to originate and maintain the ravages of epidemic disease in the East. The congratulations of their own countrymen, from the veteran Emperor downwards, have been lavishly bestowed, and no one in our own or any other nation will begrudge them the honours which they have reaped. Good work is nowhere more thoroughly appreciated than in England, but it is not the British custom to praise the workman before his work is concluded, and hence no public expression of gratitude has as yet found its way to the distinguished leader of the German Cholera Commission.

Dr. Koch and his comrades, however, are to receive something more than barren praise. A proposal has been laid before the German Reichstag to divide

amongst them the sum of 135,000 marks, or 6,750*l.*, 5,000*l.* of which will be Dr. Koch's share. The Ministry have decided that money down will meet the conditions of the case better than pensions. It may prove, they think, that the health of the members of the Commission has suffered, and that their lives have been shortened by their stay in a tropical climate, in which case a life pension would not be an equitable reward. The German government, not having a crowd of old Indians on their hands, evidently overrate the probable effects on health of a summer spent in Alexandria, and a winter in Calcutta. Still, their treatment of their scientific workers demands our admiration, and—what it will not get—our imitation.

Herr von Bötticher, in proposing the bestowal of the honorarium, spoke in very graceful terms of the services of the Commission. "It was entirely owing to Dr. Koch's readiness to place himself at their disposal, that the Government were able to send out the Commission so quickly." "The reports of the leader of the Commission had been published at once, on account of the importance and generally interesting nature of the results they contained, and the House would have recognised with pleasure, in common with the whole scientific world, and all sections of the public who were interested in the sanitary welfare of the State, how thoroughly, how competently, and how carefully the investigations of the Commission had been carried out. They might hope that when the results of these investigations had been scientifically worked out, they would succeed in arresting the spread of this destructive plague in their country. And if they ever should arrive at that result, it would be to these men, who had sought, in a fearless spirit of self-sacrifice, self-denial, and disregard of death, to solve the problem placed before them, that their thanks would be due." The proposal was carried by acclamation on Tuesday, Professor Virchow adding his eloquent testimony to the merits of the Commissioners.

The discovery of micro-organisms in connection with infectious disease is an affair of yesterday, but the gradual extinction of epidemic disease has been steadily progressing for centuries; and although the more complete knowledge of the laws which govern them must aid in their more rapid extermination, still the fact is as obvious now as formerly, that true progress lies in the improvement of the hygienic conditions under which crowded populations have to live, rather than in the destruction of this or that bacillus. The teachings of previous experience are more powerful even than the startling revelations of the present. Notwithstanding the swarms of micro-organisms with which our forefathers must have been infested, we are somehow able to show a cleaner bill of health for a vastly increased population.

The hygienic section of the Viennese Medical "Doctoren-Collegium" has lately issued an elaborate series of regulations, framed with the view of stamping out the infectious disease generally known as tubercular phthisis, and familiarly termed in the Austrian capital, from its local ravages, "the disease of Vienna." The measures proposed in this document are indeed drastic, including as they do the isolation from their relatives of all those in whom pulmonary cavities or intestinal ulcers have become developed; the prohibition of marriage under certain circumstances, and a timely caution against the use of milk derived from cows which may be suffering from bovine tuberculosis! Precautions in the way of disinfection are detailed with great minuteness, but of all these prophylactic proceedings, one, more than all the rest, seems worthy of serious application, viz., the disinfection of tubercular sputa, the rationale of which really rests upon ascertained facts, and not upon unproven theory. We shall await with interest the result of these regulations in checking the occurrence of Vienna's arch-enemy, the tubercle bacillus.

Professor Jaccoud in a lecture recently delivered at the Pitié, on the bacillus in relation to the treatment of phthisis, declares that the discovery of Koch has not in the slightest degree advanced this, inasmuch as the measures now employed were already in use by himself and others prior to the discovery being made. This we presume is not the question at issue, but whether this discovery is a fact, for if it be proved such, of course any means of treatment that may have been empirically and conjecturally employed prior to this, will be placed on a scientific basis and will be pursued with more perseverance and confidence. Professor Jaccoud shows that the same prophylactic measures, such as ventilation, disinfection, separation of the phthisical from the healthy, &c., had been taught by him in his work on the curability of phthisis; and also that he had shown that the agglomeration of the subjects of phthisis in the same hospital is innocent or dangerous to those in attendance upon them accordingly as full disinfection and abundant ventilation are put into force or not. This, too, is why contagion of the disease is unknown in the mountain sanitaria. Prophylaxis of phthisis in families in which phthisis has prevailed must commence from the very cradle; and so strongly does Professor Jaccoud believe this, that he interdicts maternal suckling even when the mother is healthy and the father only the subject of phthisis, in the fear that the wife may contract the disease from the husband and contaminate her milk. Our sole reliance has been and continues to be on the exact observance of a good hygiene. Professor Jaccoud also attaches much importance to the mechanical effects of the repeated inspiration of compressed air, which leads to an increase of respiratory capacity and its beneficial consequences. "It leads to the disappearance of the inertia of the upper portion of the lungs, ensures pulmonary ventilation and circulation, and thus prevents those stases, the consequence of inertia, which are so favourable to productions of a low order, like tubercle. The best preservative against such imperfect formations is circulatory and functional activity, and such double activity attains its maximum by this method." Professor Jaccoud has an easy task in showing that Koch's discovery has led to no introduction of new curative agents, and the blame which he attaches to the wild attempts to inject antibacteric agents into the pulmonary tissue will be echoed on all sides. "Neither

the pharmaceutical, the climatic, nor the hygienic treatment of phthisis has been influenced by the discovery of the bacillus. Its import is merely nosogenic. It simply adds another means of diagnosis, and that is the only service it has rendered, for as regards the ætiology, symptomatology and treatment it has done nothing and can do nothing." Even supposing its operation will remain as limited as here prophesied, the discovery, if it holds good, will be of no mean importance.

It appears from the "Medical Students' Register for 1883," just published, that the number of students yearly entering the medical profession is still diminishing. From 1870 to 1875, the number of new entries in each year was fairly stationary, averaging in the three kingdoms from twelve to thirteen hundred. During the next lustrum there was a rapid increase, the yearly figures steadily running up until, in 1881, the largest number hitherto recorded, viz., 2,171, was reached. Since then there has been a considerable decrease, the number falling in the year before last to 1,862, and last year to 1,783. In Scotland alone has there been no decline, last year's record, 596, being the highest yet reached. It does not speak very well for the conditions of medical education in this country to find Scotland, with a population of about one tenth of that of England, educating, and receiving payment for educating, considerably more than half as many medical students as are educated in England.

During the last five years the Registrar of the Medical Council has taken the trouble to tabulate the number of students, according the places at which they commenced their medical studies, and from these returns we have drawn up the following table, which may interest some of our readers. It may be remarked that the numbers given seldom accord with the returns published by the medical schools, for in the latter, students are often counted who commenced their studies in the provincial schools or with a registered practitioner, and who appear under these heads in Mr. Miller's tables—

A.—Metropolitan Schools.

Medical Schools.	1879.	1880.	1881.	1882.	1883.

It will be seen at a glance from this table, that while in 1879 the number of students beginning their education in London was more than twice the number of students beginning in the provinces, and only fifty less than the number beginning their studies in the three Scottish centres; in 1883 on the other hand the proportion of London to provincial students was not much more than as three to two, while the Scottish schools beat the London schools by as many as 143. In other words the number of students entering on their studies at the London schools has in six years fallen from 461 to 377, while the number entering at the provincial and Scottish schools has increased from 734 to 761. If the increase and decrease continue in the same ratio in future years, it will not be long before the conditions of medical education come to be recognised by every one as a very burning question. We ourselves have recognised and preached this long since.

We have received the draft of a bill about to be introduced into the Legislative Assembly of the Province of Ontario, enacting further provisions respecting the public health. We do not know what laws already exist in that colony, but the present bill appears to be intended to supplement the "Revised statute respecting the Public Health," by regulations for the constitution of Provincial and Local Boards of Health, distinct from the other local authorities, and by special enactments, drawn up on the lines of our Public Health Act, in respect of nuisances, offensive trades, unsound meat, and the prevention of infectious diseases, and establishment of hospitals for the same. The definition of a "house" is decidedly preferable to our own, including as it does "schools, factories, and other buildings, huts and tents used for human habitation or work, whether such use is permanent or temporary, and whether the same be stationary or moveable." Our definition most unaccountably excludes workshops where fewer than 20 persons are employed, and it has been ruled that a caravan, in which small-pox occurred, could not be treated as a house, because it was not fixed to the soil. The constitution of Local Boards of Health in every township, incorporated village and town, as well as in combined districts, is compulsory, but the appointment by such boards of a Medical Officer of Health, or of an Inspector of Nuisances, is left optional. The notification of all cases of infectious disease, *i.e.*, small-pox, diphtheria, scarlatina, typhoid fever, and cholera (typhus is not mentioned), within 24 hours of their recognition, is enjoined on both householder and medical attendant, and neither the patient nor his clothing may be removed from the house without the knowledge and approval of the Board of Health, its medical officer, or the medical attendant. Two very comprehensive schedules describe the duties of Boards of Health and their officers, and lay down rules for the construction and ventilation

of drains, closets, &c., and also provide for extending the notification to measles and whooping cough, when these assume the proportions of an epidemic, with the exhibition of a notice board on infected houses. The Medical Officer of Health is required to furnish to all medical practitioners forms for giving full particulars of every case of infectious disease, including the name of the schools attended by any children from the infected house, and the termination of the case in death or recovery.

The University of London Lodge of Freemasons, which has long been talked about, was formally consecrated at Freemasons' Tavern by Lord Carnarvon, Pro.-G. M., on Wednesday last, after the annual presentation ceremony at the University. The new Lodge will take rank with the Apollo Lodge of Oxford and the Isaac Newton Lodge of Cambridge, and will be confined to Members of the London University. Brother F. A. Philbrick, Q.C., was installed as W. M., and among the medical graduates who were founders and first officers of the Lodge are Dr. Meadows, Dr. Gooding, Dr. Sansom, and Dr. Curnow. A Banquet was held in the evening. Amongst the speakers at it were Sir Francis Burdett, Mr. S. Pope, Q.C., and Mr. Edward Clarke, M.P., all of whom expressed the heartiest good wishes for the welfare of the new Lodge. In these we may cordially join. It will doubtless be a great gain both to Freemasonry, which will secure an increased number of recruits from amongst University graduates, and to the University, which has long needed some such bond of union amongst its members.

It is with great gratification that we are able to announce that Dr. Buchanan Baxter, after passing through a prolonged and anxious illness, is at length well enough to resume his work.

A copy of the official catalogue of the International Health Exhibition is before us; it is the most confused and the worst compilation of the kind we have ever seen. The cardinal defect is the omission of a classified index, so that it is impossible to know how many exhibits illustrative of a particular subject exist, save by reading most of the catalogue itself; the text is interspersed with little feeble essays on food, dwellings, &c., and advertisements. We trust a second edition will immediately replace this unfortunate production. Why should not the catalogue of the first Health Exhibition be a literary work in the truest sense of the word, one that students of hygiene would bind and preserve? Such a catalogue would have redeemed many little defects in the management, and if properly arranged, would have enabled the visitor to at once find any particular object he happened to be in search of.

Professor Gaillard Thomas, in a lecture recently delivered at the New York College of Physicians and Surgeons, drew attention to the fact, that among the nineteenth-century women there are two classes; the distinction between them has probably existed for many previous centuries, but to the exigencies of modern civilisation seems to be owing its present broad and well-marked outlines. The one class, we are told, comprises those women who desire, above all things, to become pregnant and to bear children; and the other, those who are anxious, above all, not to bear children. With the latter class the lecturer does not further concern himself; as regards the former, he points out that their disappointment is, in many cases, due to a habit of aborting; and further, that about eighty per cent. of miscarriages take place at the end of the third month of utero-gestation.

Two factors make for such an occurrence. Firstly it is at this period of intra-uterine life that the placenta is becoming completely formed, while the chorion is disappearing; and this period of change in the method of fœtal nutrition from the chorionic—in which blood is derived from the whole intra-uterine surface—to the placental—in which blood is drawn from only a limited portion of the uterine wall—is a critical one, fraught with liability to dangerous complications. Secondly, it is at the end of the third month that the pregnant uterus begins to rise above the pelvic brim; and if its supports be weak, so that the organ suffers something of a flexion or a version, the nutrition of the fœtus may be thereby deranged, and the further continuance of utero-gestation imperilled.

Putting aside various possible causes, such as slight but irritable cervical lacerations, irritable granulations about the os uteri, extreme nervous conditions, &c., there are two great *causes* of habitual abortion. The first is stated to be a posterior displacement of the uterus, which interferes with the proper development of the organ. This may often be so slight as almost to escape detection in the non-pregnant state; but a careful digital examination, with the woman standing in the erect posture, will show the uterus to be lying a little posterior to the line of its normal axis; and a slight further deviation backwards, such as is apt to occur in the pregnant organ from its increased weight, is sufficient to induce miscarriage at the third month. As regards treatment, should a woman in this condition, who has previously aborted, again become pregnant, she should be carefully watched, and be examined every four or five days, or at the longest once a week. If by the end of the second month the uterus is found bent farther backward than at the end of the first month, the patient should be placed in the genu-pectoral position, the uterus gently pushed over into its proper place, and a pessary inserted to maintain it in position. Supported in this way the uterus is able to rise out of the pelvis as it enlarges, and pregnancy is, therefore, allowed to go on.

The other great cause of abortion at this period is, of course, syphilis. "The moment I see a woman who tells me that she aborts regularly at the end of the third month, I am so certain of the cause that I say to myself, that she has either a slight or a great displacement of the uterus, or else there is syphilis in the family." "Syphilis," says Dr. Thomas, "certainly developes accidentally sometimes;" and he thinks it

unwise of the physician to scout and disbelieve the statements as to the extraordinary and unusual methods by which the disease has been innocently contracted, which are occasionally put forward. As a case in point, he gives one instance which is ingenious, if not convincing. "I have known," he says, "of the case of a sewing woman in this city who became infected with a true Hunterian chancre, followed by a secondary eruption, apparently in the following way: she accidentally pricked herself in the breast with a pin which had, probably, retained upon it syphilitic virus from the hand of the woman in France who had made it, and who had, doubtless, just been dressing her chancre previously to sticking the pin on the paper to send to this country, where it was destined to infect her innocent sister." Charity, doubtless, may well be accorded a place in many a clinical lecture; and something, perhaps, may be said for that charity which—beginning (and staying) at home—makes an unknown foreigner the "doubtless" cause of the disaster, and which appears to credit every workwoman in France with "her" evidences of a loathsome and disreputable malady; but we cannot concur in the desirability of setting such a story before students as an example of the way in which a scientific physician gathers his evidence.

"NON POSSUMUS."

The hopes which a few sanguine spirits entertained, that the great meeting of the Fellows and Members of the College of Surgeons in March would possibly mark the commencement of a new era in the policy of the College, have been rudely dispelled. The Council devoted the greater part of their protracted sitting on Thursday week to a consideration of the resolutions adopted at that meeting, and their decision on the various proposals submitted to them was recorded in our last issue. To all but one of these proposals their reply is simply, "Non possumus." That such would be the case, one was almost prepared to expect, considering the rumours which have been freely circulated in professional circles during the last few weeks. Still the report of the Council's proceedings will have been read with not the less widespread disappointment, because their action had in many quarters been accurately forecasted. The Council, we believe, have finally decided to carry into effect the changes which they had already agreed upon, and which they only submitted to the meeting of March 24th *pro formâ*; but, as we have already said, with one exception, they have determined *not to take action* on any of the independent resolutions which were passed by the meeting, on the Council's express invitation. One concession they have made, it is true, but in such a modified form as to deprive it of all meaning. They are willing to allow an annual meeting of Fellows and Members to be held, at which *a* report of the Council shall be "presented." But they have carefully guarded themselves against the assumption that they are in any way responsible to such meeting by striking out the words "received and adopted." The Council, in short, preserve their right of reporting to the meeting, but apparently will not admit the right of the meeting in its turn to discuss or criticise their report. Could any concession have been made in a more grudging or pedagogic spirit?

How much is likely to be gained from such a series of annual meetings may not unfairly be estimated from the results of that recently held. The Council evidently either decline to accept the major premiss, which we hold in common with all other advocates of reform, viz., that there is strength in the popular principle of representation, and hence see no force in our conclusion, that their power will be living and beneficent in proportion to the breadth of the base on which it rests; or else they have decided that the March meeting was not a sufficiently representative one to warrant their taking action on its proposals. In the former case we have nothing further to say, but must patiently wait for a more modern-minded Council. In the latter case, *i.e.*, if the meeting were not felt to be representative enough, surely it is incumbent on the Council to summon another before applying for powers to carry out those changes in the charters to which it was thought necessary to gain the assent of the Fellows and Members. If the absence of a large proportion of the holders of College diplomas implies consent in the one case, it ought to imply consent in the other. In fact, the Council must know that the proposals of Mr. Paul Swain are cordially acquiesced in by the vast majority of the Fellows and Members, who would undoubtedly have attended in much larger numbers had they not accurately foreseen—as the event proves—that all action on their part would be fruitless.

We deeply regret the course of action—or rather of inaction—pursued by the present Council. It cannot fail to stir up a feeling of resentment, which will more and more estrange the Fellows and Members from the College, and add to the proverbial instability which characterises a house divided against itself. As to the great desirability of a truly representative Council, no one, except the members of the present irresponsible executive, is in doubt; while few will question the value to the profession at large of a sense of personal responsibility on the part of its members to some central Institution, or the controlling effect of such a sense of responsibility on the actions of each individual Fellow or Member. The College of Surgeons, almost less than any other public Institution, appears to exercise authority—good, bad, or indifferent—over its members. There is an entire absence of *esprit de corps*, and an entire want of interest among the members, both in the parent Institution and in each other. In this respect the College is curiously unlike all other public Institutions, and this failing is not only an inevitable source of weakness, but a cause of many of the backslidings that are unfortunately to be found among the rank and file of the profession. We shall watch with some curiosity the further development of events. The Fellows will presumably show that they know how to exercise the power which they undoubtedly possess. The election to the Council of Fellows pledged to bring about the much needed and wholesome changes, is the first and most obvious if not the only effectual method of rousing the Council to a sense of their representative position, and to the necessity of doing that which will meet the wishes of the majority.

But the Members, too, must organise their forces. By their numbers, if in no other way, they can exercise great weight at the annual meetings which are now to be held; they can petition Parliament against any changes of the present charters which do not bring with them that direct representation on the Council which will give them a voice in the management of the College. But for this something better than the present association of members will have to be organised. Time and trouble and money are required to call into existence an association which shall be representative of 16,000 men. A more propitious meeting time and place must be arranged by mutual consent, and if the promoters of the movement are wise they will elect to rally their forces at a time when some public occasion draws medical men together, such as the meeting of the British Medical Association. It is easy enough to indicate the directions in which good work may be done; let it be done good-naturedly and quietly. The successful result is but a matter of time.

THE SOCIETY OF THE ART AND MYSTERY OF APOTHECARIES.

Mr. Henry Bullock, in a letter which we publish elsewhere, complains that in our leading article of last week we have done "a considerable amount of injustice to the Society of Apothecaries, and through them to the ten thousand licentiates." He has evidently not grasped the meaning of our remarks if he thinks we shall admit that injustice to the Society is the same thing as injustice to their licentiates; but we do not even admit that we have been unjust to the Society, nor do we think Mr. Bullock's letter will persuade any reasonable being that we have been unjust. We cannot again discuss the constitution of the Society, but we may state briefly, that of the four-and-twenty gentlemen who rule it, the oldest must be over eighty and the youngest can scarcely be less than sixty-six; that the masters and wardens are evidently elected solely by seniority; and that there is so little circulation, except as the result of death, in the Court of Assistants, that, according to the last published list, only two retired members of it are in existence. Mr. Bullock asks whether certain members of the Court of Examiners are not fit and proper persons to have a voice in the direction of the medical education of the future? It will be time enough to answer this question when Mr. Bullock has assured us that the representative of the Society on the English Medical Board, supposing one to be granted, would be chosen by the Court of Examiners. Of course, if this were so, if, too, the apprenticeship system were still recognised as an integral part of the medical curriculum, and if, again, the Society still elected general practitioners as its examiners, and not young consultants, why, then there might be some semblance of an argument in favour of the proposed representation on the Medical Board. But Mr. Bullock places himself in this dilemma: Either the representative would be elected by the Court of Assistants, in which case he would be chosen by a self-elected committee of very senior gentlemen, with no recent knowledge of the conditions of medical education and examination, or he would be elected by the twelve members of the Court of Examiners, nine of whom are Members or Fellows of the College of Physicians, and have therefore presumably no special claim as general practitioners—even accepting Mr. Bullock's view—to influence medical education. But we do not accept Mr. Bullock's view. We have the greatest respect and admiration for general practitioners, but we cannot admit that they are more practical men, or a whit more likely to conduct examinations on practical lines, than "pures and specials." We cannot for the life of us see why the twenty-four gentlemen who govern the Society, or the twelve gentlemen whom they choose as their examiners, have any greater right to seat a member on the English Medical Board than any twenty-four senior general practitioners, or any twelve junior consultants chosen at hap-hazard.

Mr. Bullock says that the Society was, in 1815, constituted "an examining body in the Art and Science of Medicine." If so, it is unfortunate that it should still retain on its diplomas the style and title which stands at the head of this article. The perpetuation of the word "mystery," smacking as it does of the worst traditions of medicine, would seem to show that the modern scientific spirit has been felt as little in the cloistered peace of Apothecaries' Hall, as, to judge from some recent evidence, it would appear to have been felt amidst the turmoil of Printing House Square close by. There are many of course who will regard this cleaving to old fashions as a point in favour of the Apothecaries' Society. No one, indeed, who has any reverence for time-honoured institutions will fail to regret the inevitable sacrifice of the Society to the logic of events. There seems, however, to be no help for it. For, once accept and legislate on the principle that there shall be a uniform qualifying examination for all medical practitioners, and there remains no longer any excuse for the existence, as an examining body, of a corporation whose *raison d'être* hitherto has consisted in its power and practice of giving an inferior qualification. The Apothecaries' Company is now suffering, or doomed to suffer, as a result of the short-sightedness of its executive in the last generation. If, forty years ago, the Society had re-constituted itself on a popular basis, changed its name, which has always been a stone round its neck, and, strong in the loyal support of its licentiates, had strenuously resisted the attempt of the College of Physicians to give a general practitioner's diploma, it might have become the most powerful and popular medical body in the kingdom—occupying something of the same position that the British Medical Association now holds. But it preferred to retain its gerontarchical constitution, and to let the College of Physicians oust it from its own particular field, so that no one but its own licentiates, and probably not very many of them, would now stir a finger to prevent its being relegated to its old position as a simple City Company. Even the writer in *Blackwood's Magazine*, who fights strenuously enough in behalf of the other Corporations, is forced to admit that the Apothecaries' Society must submit to effacement.

We sincerely trust that the Government will not be persuaded against their better judgment to reinstate the

Society in the place from which they have so wisely excluded it. That would be to take away from it every incentive to reckon with circumstances and boldly to strike out a novel line. If they could only see it, the rulers of the Apothecaries' Society have the possibility of a great and successful career still open to them. Before the Medical Bill, should it pass without tangible modification, has been in operation for many years, it is quite likely that there may be a great and irresistible demand for a lower grade of Medical Practitioners. Even now medical men are above the places which many of them must take, and when the law demands of them a still higher culture, and a still more prolonged and costly education, it will be found, we fear, that the poorer populations in town and country will be entirely deserted by the doctors and left to the tender and ignorant mercies of the herbalist and prescribing chemist. Then there will be an outcry, and the public will demand either that the chemists shall receive some smattering of medical education, and be allowed to visit patients and treat them, or else that a lower grade of medical practitioners shall be called into being for the service of the poor. The latter course would certainly be the more sensible one, and if we could once get over the old idea, which has met with little support outside the profession, that a doctor must of necessity be a gentleman, a very useful and excellent career would be opened to many of the picked pupils of the Board Schools. They would not be above their work, and would not regard their fees, as so many medical men in poor districts do now, as out of all proportion below the value of their services. The doctor of to-day often feels that to take a small fee is to do injustice not only to himself but to his profession, the standing of which, as a whole, seems lowered by his act. He has moreover to keep up a certain position in accord with his assumed social superiority to the trading classes, and he cannot do that on exiguous fees. But once recognise a lower grade of practitioners recruited from a lower class, and trained in a less costly manner, and no indignity would be felt by them in accepting the only fees that the labouring classes can afford to pay. And the community would be a direct gainer from the fact that a class of cases which now fall into the hands of chemists and herbalists, would then be treated by men with some medical training, however short it might fall of our present standard.

If this innovation be ever brought about, it will be to the Apothecaries' Company or to the Pharmaceutical Society that the Government will turn, as the proper authorities for controlling this new departure. And the two Societies, as suggested by the writer in *Blackwood*, might very advantageously form an alliance for the examination of the new practitioners who, if their education is to be a really cheap one, must be in great measure trained on the old apprenticeship system. In such a case the Apothecaries' Society would have a fair claim to control the examinations. The new practitioners must of necessity be allowed to keep open shop, as were the apothecaries of old, for the economical conditions of poor neighbourhoods do not admit of that more expensive specialisation of function which obtains amongst the well-to-do. If then the Apothecaries' Society can make up its mind to give up its hopeless attempt at rivalry with the Colleges of Surgeons and Physicians, and be content to take a lower place, it may still in the not far distant future find a useful and lucrative *rôle* opening before it. Otherwise, it seems to us, it must put up with a position, distinguished only from that of other City Companies, by its trading privileges. These views that we have put forward will no doubt be considered in many quarters as heretical. But the heresy of one generation is not unapt to become the orthodoxy of the next; and no advantage is gained by holding on to worn-out conventions when the current of events is sure, sooner or later, to tear us away from them. As it is, the line of cleavage between the doctor who dispenses and the doctor who prescribes is much more clearly marked than any that exists between the physician or surgeon and the general practitioner. There is at present no single differentia sufficient to distinguish every physician from every general practitioner, and as time goes on, and the upper ranks of the profession become more crowded and the lower more ambitious, the faint line that at present divides them will become a vanishing one. It would be unadvisable, even were it possible, to perpetuate it, for the course of events will inevitably draw the line elsewhere. The State has already acknowledged the principle of a lower grade of practitioners by constituting the "Dentists' Register;" and as every man of sense saw at once that it was impossible to demand that every dentist should be a perfectly educated medical practitioner, so, we believe, it will one day be admitted, that if the poor are not to be left in the hands of the chemists, we cannot enforce an ideal medical education on their attendants, but must be content to institute a lower grade of medical practitioners, who will stand in the same relation to the regular practitioner that the apothecary once held in relation to the physician.

SMALL BEER IN LUNATIC ASYLUMS.

Dr. Murray Lindsay, in his report on the Derby County Asylum, for the year 1883, is content to "chronicle small beer," or rather to record with enthusiasm the triumphs of that system of which he is an earnest apostle, of depriving pauper lunatics of their small beer. We admire his courage for writing as he does on the subject, while living within a few miles of Burton-on-Trent, and with the solemn names of Bass and Allsopp ever sounding in his ears, but we cannot help thinking that he misapprehends the points at issue in this great contest on beer, by which the medico-psychological world is now torn asunder. The question is not whether it is economical to withhold their modest tumbler of malt liquor from the inmates of our asylums, but whether it is justifiable to do so; not whether it is convenient, but whether it is humane. To mix up with this question discussions as to the utility of alcohol as an article of diet, or as to the social advantages of total abstinence, is to betray hopeless confusion of ideas. A lunatic is not, we apprehend, by the mere fact of his lunacy reduced to the status of a lower animal, or of a baby-in-arms. The

whole modern system of the treatment of the insane is founded on the recognition of the fact that a lunatic retains his manhood in spite of his disease, and is to be treated as a reasonable being, except in so far as his own safety, or that of others, demands that restraint should be imposed on him, or in so far as it may be necessary to insist on a certain course of treatment as conducive to his restoration to health. Now Dr. Lindsay will not contend that a glass of beer jeopardises the safety of the lunatic, or of the public, or, in ninety-nine cases out of a hundred, interferes with his prospect of recovery. Why then should a grown man, who has been in the habit of taking a glass of beer all his life, be converted into a teetotaller against his will? Why should he, when labouring under a grievous affliction, when separated from his family, and shut up with anything but desirable companions, have his sufferings aggravated by being denied what he regards as a solace, and what is at any rate a harmless indulgence? Custom and association have made a glass of beer a symbol of comfort and enjoyment to many of the most respectable of the working classes, and we know of no argument by which compulsory blue-ribbonism, any more than compulsory Mohammedanism, or compulsory agnosticism, can be defended.

Alcohol is unnecessary as an ordinary article of diet, says Dr. Lindsay. Of course it is, but the term unnecessary, as he uses it, is a very comprehensive one; and if pauper lunatics are to be cut down to what is absolutely necessary, their existence will become somewhat bald. Tobacco is unnecessary, beef and mutton are unnecessary, and so are tea and coffee. Does Dr. Lindsay propose to put a stop to the use of these articles in the establishment under his care? Those elaborate theatrical performances that Dr. Lindsay provides for his patients, and in which the asylum officers so proudly strut in fancy costumes, are, it must be allowed, quite unnecessary. Oh! but Dr. Lindsay will reply, these entertainments are eminently beneficial, by inducing a cheerful frame of mind, and that is just what we would contend for in the case of the small beer—that it is eminently beneficial by inducing a cheerful frame of mind, less, like the theatricals, by its inherent qualities, than by the associations that its name and outward semblance summon up. Let a vote be taken by impartial authorities amongst the patients in Dr. Lindsay's asylum, between theatrical performances and small beer. We have not a doubt that the drama at the Derby Asylum, with all its pomp and histrionic ability, will have to give place to the despised and unnecessary beverage.

Dr. Lindsay asserts that the health of the inmates of his asylum has not in any way deteriorated since the beer ration was stopped. Now it is quite possible that a considerable deterioration of health may take place in a community without any evidence of it being discoverable in the death-rate or medical returns, and Dr. Lindsay is not entitled to speak dogmatically on this point unless he has a very complete series of weighings of his patients, with and without the beer ration, to appeal to. And even then the point would not be definitely settled. Our prison authorities will tell Dr. Lindsay that it is possible to put a man on bread and water for three days once a fortnight for a considerable period without any loss of weight indicating failure of health; but can any medical man doubt that such a regimen would result in impairment of health and vigour in the long run? Comfort is a safe practical guide to health, and if a small quantity of beer in the dietary of an asylum conduces to the comfort and satisfaction of the inmates, then it may fairly be argued that it makes for health. But Dr. Lindsay himself supplies grounds for believing that the withdrawal of beer cannot have contributed to the higher health of his patients. This withdrawal has, he says, resulted in a saving of 410*l.* per annum, that is to say, about 1*l.* per patient. But the whole food of each patient, as far as we can judge from the accounts, does not exceed 10*l.* per annum, and thus about one-tenth of the nutriment formerly allowed to them has been taken away. The dinner of the patients on one day a week consists of one pint of soup and six ounces of bread, on another, of six ounces of bread, fourteen ounces of meat, and potatoes, pie, and fourteen ounces of suet pudding, and anyone who is familiar with public-institution cookery on the large scale will believe that on the suet-pudding day at any rate a pint of small beer would be an agreeable addition to the mid-day meal. There would have been less objection to the withdrawal of beer from the asylum dietary had compensation in the form of meat or milk been given, but to stop the beer and pocket the price of it is scarcely a commendable proceeding. Asylums are not workhouses, but in hospitals and asylums economy is a secondary consideration when compared with efficiency and the comfort and happiness of their afflicted inmates. That the stoppage of beer in asylums is a tyrannical proceeding is evidenced by the fact, that in the case of nurses and attendants who can make their grievances heard, the value of the beer has been paid to them in money, so that they can buy their own beer; while in the case of the patients, who have no appeal, no compensation of any kind for the intercepted small beer has been granted.

REVIEWS AND NOTICES OF BOOKS.

LAWSON TAIT ON DISEASES OF THE OVARIES.[1]

We doubt if there be any surgeon of the present day less trammelled by authority, or bolder in risking his reputation than Mr. Lawson Tait, of Birmingham. His courage and his skill have brought him an enormous field for experiment, and been rewarded with unprecedented success. Therefore, a book by him on his special subject, must excite the interest, and command the attention of all who are ever called upon for their advice in cases of the kind described in it. Mr. Tait's work is full of originality. That which chiefly detracts from its excellence as a scientific treatise is that we are generally called upon in it to

[1] The Pathology and Treatment of Diseases of the Ovaries (being the Hastings' Essay for 1873), by Lawson Tait, F.R.C.S., Ed. and Eng., Surgeon to the Birmingham Hospital for Women, &c. &c., fourth edition, rewritten and greatly enlarged, pp. 357. Birmingham: Cornish, Brothers, 1883.

take the results with simple, unquestioning faith in the accuracy of Mr. Tait's judgment. He does not sufficiently supply the information from which an independent thinker might form an opinion for himself. We do not for a moment attribute to Mr. Tait any intention other than that of arriving at the truth, and making it known as fully and exactly as he can; nor do we doubt that his conclusions are supported by the facts of the cases under his own care, so far as they are known to him. But he does not state his reasons and results in such a form as to convince a scientific sceptic that every discoverable source of error has been eliminated. We could imagine him saying to the medical world—

> "We'll not insult thy majesty by time,
> Person, and place: the where, the when, the how,
> And all particulars that dull brains require
> To constitute the spiritless shape of Fact
> They bow to, calling the idol, Demonstration"—

were it not that the tone of this quotation is far too deferential to accord with that of Mr. Tait's writings. He uses ambiguous phrases without explaining what he means by them. For instance, speaking of the removal of diseased Fallopian tubes, our author says (p. 66), "All my patients—22 in number—have recovered, and of those in which a sufficient time has elapsed since the operation, I can say confidently that they are all completely cured." This seems to us a sentence devoid of definite meaning, unless we know (1) what is "a sufficient time," and (2) how many of the cases have been watched during that "sufficient time."

But it will be more profitable, without lingering on features which disappoint us, to give our readers some idea of the important peculiarities in opinion, and novelties in practice, which are put before the profession in this work. The chief among them are already familiar to most, from the discussions upon them which have occupied our medical societies. Mr. Tait is a strong disbeliever in Listerism; he thinks it worse than useless, and rather prejudicial to success than otherwise. He brings forward strong arguments, as well as the astonishing results of his own experience, in refutation of the popular belief on the subject. It appears to us, that if Mr. Tait's opposition is regarded as directed only to certain details with which he dispenses, he has established his case. But a broad fact which Mr. Tait cannot overturn, is this: that there exist hospitals which, before Sir. J. Lister's teaching became influential, were little better than slaughter-houses, in which, since their surgeons have adopted Listerism, the major operations in surgery have been performed with unprecedented success—we allude, of course, to hospitals on the Continent; and that in London hospitals, we see cases in which, before Listerism, a free discharge of so-called "laudable pus" was thought a healthy sign, but in which now the surgeon reproaches himself if he sees any pus at all. When these results can be obtained without Listerism, then Listerism will be dead, but till then Mr. Tait's attacks will not kill it, and, we hope, will not check its use.

Mr. Tait has introduced the extirpation of diseased Fallopian tubes. In this we believe him to be a true pioneer; but he is not a road-maker, for he frankly says that he cannot teach others how to diagnose the cases or perform the operation. The establishment of this operation, as a recognised resource of surgery, has to be done in the future.

Mr. Tait points out one useful diagnostic point between ascites and ovarian dropsy, which we do not remember to have seen described before. It is, that in ascites by deep pressure a dull percussion note can often be altered to a resonant one; the explanation being, that by this manœuvre the layer of fluid over the intestine is pressed away, and the clear note of the bowel becomes audible. In ovarian dropsy, on the contrary, by deep pressure a resonant note will be changed to a dull one, because by such pressure the abdominal wall is brought into more extensive relation with the tumour, and any intestine overlying it is squeezed aside. Mr. Tait advances an important view with regard to the relation of ovarian dropsy to malignant disease. He holds, "that the growth of ovarian tumours is associated with a tendency towards malignant disease." If this view be correct, it establishes, as he points out, "the absolute propriety of removing ovarian tumours at a very much earlier stage of their existence than has been, till recently, the accepted rule in practice." It follows further, that tapping should be discarded, except under very exceptional circumstances, as being attended not only with some immediate danger, but with a risk of secondary infection of the system with cancer. Mr. Tait does not place confidence in the diagnostic conclusions which, according to some observers, are to be drawn from the microscopic examination of the fluid removed.

The first chapter of the work treats of the anatomy and physiology of the ovaries, and in this field, as well as in the clinical one, Mr. Tait has observed and thought for himself. He rejects the view of certain German investigators, according to which the ovary forms a singular exception to rule (very difficult, it always seemed to us, to understand), in being, unlike every other abdominal viscus, devoid of a peritonæal covering. Mr. Tait finds, as the result of a special research, that this investment is represented by a layer of squamous epithelium which covers the whole gland. Another new and interesting point is, that in a few cases he has seen "a crescentic double fold of the posterior layer of the broad ligament pass down behind the ovary," covering it like the hood of a "Nepenthes" gland. "In all such cases," he tells us, "the women have been sterile, probably because this hood has prevented the application to the ovary of the opening of the oviduct." Another commonly accepted belief which Mr. Tait would overturn, is that as to the medico-legal value of the corpus luteum. He says, "After a very extensive acquaintance with ovaries, I would not venture to give an opinion from any number of corpora lutea, as to whether they indicated past pregnancy or not." His view on this point is supported by a paper by Dr. Popow, read last year before the Obstetrical Society of London.

The pages dealing with the clinical aspect of imperfect development of the ovaries and oviducts, seem to us to contain statements open to grave doubt. Thus, we are told, "epilepsy is only too common an accompaniment of arrested sexual development in women," and the drift of the passage (page 39), too long to quote in full, is to leave the impression that the epilepsy is the result of the developmental error. On the next page we find, "the great bulk of cases of this kind are those which are afflicted to a less degree, but whose sufferings are nearly always sufficient to require medical assistance." It is a fact, as Mr. Tait mentions in his next sentence, that many of the subjects of this sexual defect are women of "splendid physical development," and (which he does not say) free from any symptoms of ill-health beyond the non-performance of some sexual functions. Is it not probable, from the obvious fact that persons who feel well do not commonly seek medical treatment, that the subjects of the type last mentioned, whom gynæcologists see, are less numerous than those whom they do not see? Is it not also well known, that all conditions of serious ill health, affecting girls in

whom puberty would be otherwise at hand, tend to delay it? And among such conditions are not idiocy and imbecility—conditions often associated with epilepsy and with deficient physical development generally—prominent? Looking at these facts, it appears to us sounder pathology to regard the cases in which, with deficient uterine and ovarian development, no symptoms are present—the subject, indeed, enjoying robust health—as the rule; and as a demonstration, furnished by nature, that deficient sexual development does not cause ill health: and to regard the condition of the sexual organs in the class of epileptics alluded to, as merely one result of the generally defective health. Mr. Tait recommends the galvanic stem in cases of deficient uterine development. We should much like to see published a series of cases in which this instrument has been used. Our author does not supply it. He has removed the ovaries for "menstrual epilepsy," but the cases are too few and too recent to warrant any conclusion from them.

Mr. Tait does not mince his language. Indeed, he sometimes uses words stronger than seem to us warranted. Thus (p. 43), we are told that the sound, which many gynæcologists consider useful, and employ thousands of times in the course of every year, without any suspicion that they are submitting the patient to an appreciable risk, is a "most dangerous implement . . . it has done an infinite amount of mischief, and probably we should have lost nothing if it had never been invented." On p. 159, we are told, "the patient died on the fifth day, as was usual when the clamp was employed." Surely, when 75 per cent. of the patients recovered, it is too strong to speak of death as "usual."

As an example of readiness, boldness, and originality of resource, and of what may be done with success, we may quote the following:—"A few days ago I removed a tumour universally adherent, full of pus, and quite rotten. I tore across the pedicle before I had recognised it, and its vessels bled profusely. Like the rest of the tissue it was quite rotten, and the more I tied the vessels, the more they bled. The cautery was equally useless. I therefore secured all the points by means of forceps, and left them *in situ* in the abdomen, closing the wound over them. I reopened it in twenty-four hours, removed the forceps, refastened the wound with a drainage tube at its lower angle, and the patient made an uninterrupted recovery" (p. 283).

Mr. Tait, in describing the history of ovariotomy, seems to have much sympathy with Mr. Baker Brown, and to regard him as a man whose career was cut short by unjust condemnation. On the other hand, he seldom mentions Sir Spencer Wells, except for the purpose of implied or expressed disparagement. All that we need say on this point is that Mr. Tait has either not studied the controversy which ended in Mr. Brown's discomfiture, or he judges that surgeon's conduct by a standard very different from our own.

Our notice has reached a greater length than we intended. The extraordinary interest and value of the book have drawn us on as we wrote. To sum up our judgment (many points in which space forbids us to illustrate), we do not know any work which gives so full, so clear, and so practical an account of the diagnosis of ovarian tumours, the performance of ovariotomy, and the after-treatment of the the patients. We think it has seldom happened that a book on any subject has been published which breaks so much fresh ground, points the way to such brilliant victories over disease, as the one before us. But, as we have said, its merit is that of a pioneer, of an explorer, not that of a road-maker; to use the military metaphor, Mr. Tait seems to have conquered a new territory, but he has not yet so organised it, that it is safe for other travellers to follow. The work is suggestive and dogmatic, rather than demonstrative.

DENUCÉ ON INVERSION OF THE UTERUS.[1]

We have much pleasure in expressing our high appreciation of this most laborious and valuable work. It is a historical and clinical treatise, of an elaborate and exhaustive kind, on an exceedingly rare disease; and for this reason is of more interest to specialists than to general practitioners, most of whom will, probably, pass their lives without ever seeing a case of the kind. Some such monograph was needed; for, since the publication of Crosse's famous essay on uterine inversion, a great advance has been made in its treatment, in the use of the repositor perfected by Dr. Aveling. Improvements have also been made in the methods of removing the inverted uterus in cases in which reduction is deemed impossible.

Dr. Denucé's essay is clearly written, and very well arranged. He has spared no pains to make it complete; indeed, the only fault that we are inclined to find is that too much trouble has been taken; that little points of detail are discussed at a length, as it seems to us, out of proportion to their importance, and that obsolete modes of treatment are described as fully as those which have superseded them. But these are, if we may use a paradoxical phrase, good faults. We beg leave to congratulate Dr. Denucé on his work, and to thank him for it.

Year-Books of Medical Progress: Therapeutics for 1883. Dr. Amidon, pp. 247. *Surgery for* 1883. Dr. Knight, pp. 197. Putnam's Sons, New York and London, 1884.—The two books alike in all save their subject-matter, are intended each to give a condensed review of some of the many contributions made during the past year to the subjects of which they treat. We gladly welcome such aids to universal knowledge, for memory is often treacherous; without such reminders as the perusal of these books afford us, good papers are apt to escape us, and much useful information to be lost which might otherwise prove useful to us. The surgical book loses much of its value from being issued without either a table of contents or an index. The therapeutics would be improved if the index were more copious. If such works are to be really useful, besides being as complete as possible, they should be well up to date, and every paragraph within easy hail of the reader. The paper, printing, and style are beyond praise.

Scrofola e Sifilide; studio del Dott. Sebastiano Giovannini (Scrofula and Syphilis). Bologna: Gamberini and Parmeggiani, 1884.—This "study" is the reprint of an article which recently appeared in the *Bullettino delle Scienze Mediche di Bologna.* It consists of 139 pages of closely printed matter; it is not divided into chapters; it has no table of contents, no headings to the paragraphs, no catchwords, and no index. Under these circumstances, the book is not likely to attract readers. The gist of the "study" is to show that its author sees no reason to admit of the existence of a special scrofulous habit. The milder forms of scrofula (so-called), both of the skin and of mucous membranes, are merely the ordinary phlogistic processes; they have minor analogies with syphilitic affections; the remaining (so-called) scrofulous processes are really localised manifestations of tuberculosis. Both scrofulous and syphilitic processes have an infective origin: the former can be carried in the air, the latter cannot; both produce local lesions at first, which tend to generalise themselves if the soil prove suitable. The scrofulous virus may propagate itself acutely, as general miliary tuberculosis, in this respect resembling acute syphilis, but with very different sequelæ. When scrofula and syphilis affect the same person at the same time, each runs its own peculiar course. The possible origin of scrofula from a worn-out syphilitic diathesis is discussed; the author appears rather to lean to such a view.

ABSTRACTS AND EXTRACTS.

SURGERY.

THE ADMINISTRATION OF ETHER BY THE RECTUM.—M. Mollière, Surgeon-in-Chief of the Hôtel Dieu, Lyons, gives an account of some operations for which, at the recommendation of Dr. Yversen, of Copenhagen, he induced anæsthesia, by administering ether by the rectum. Only a small quantity was required, which was given by means of a double tube and Richardson's pulverizer. The results were very satisfactory, and M. Mollière believes that this method is likely to render great services. It suppresses the stage of excitement, and the dose employed, which is reduced to a small quantity, can be strictly measured, while in operations on the face, the apparatus is not in the way of the operator. The inspiration of ether, too, which to some patients is so odious, is avoided. Further trials are required to fully estimate the value of this mode; but, thus far, it may be stated that in order to obtain deep anæsthesia, with a very small quantity of ether, it suffices to introduce a caoutchouc tube into the rectum, and bring this into communication with the ether flask, placed in a recipient containing water at from 40° to 60° C.—*Lyon Médical*, March 30th.

TREATMENT OF FRACTURED PATELLA.—Dr. Jalaguier, in an eminently French, but very interesting, paper in the March and April numbers of the *Archives Générales de Médecine*, discusses the "new methods" of treating fractured patella—aspiration of the effused blood or other products, and suture of the fragments, after opening the joint—the former operation being "*une étape de transition*" between the old method, which respected the joint at any cost, and the new one, which lays it freely open. The author gives summaries of all recorded cases, and traces the histories of the two operations. It is curious to note that the line of argument against aspiration of the joint, when this operation was first introduced, is very similar to that used now-a-days against the infinitely more serious one of free incision. For aspiration met with a very adverse criticism at the hands of the Société de Chirurgie of Paris, in 1872, when M. Dubrueil related a case in which he had practised this operation, which was followed by formidable complications and ultimately proved fatal. It had long been recognised by surgeons that effusion, either sanguineous or not, into the knee joint after fracture of the patella was the chief cause which interfered with the approximation of the fragments; no wonder, however, that after such an expression of opinion by the Surgical Society, the operation languished, and, indeed, never became popular in France. In England and Germany, however, it has been practised with success, and by many surgeons is even now considered the best operation in order to bring about coaptation of the fragments. The graver operation of opening the joint is legitimately a subject on which there is room for differences of opinion. Many surgeons reject the operation because satisfactory results can be obtained without it. Such a position is absolutely unassailable, and Verneuil thinks it unjustifiable to run grave risks by opening the knee, while such results can be obtained. Our author discusses all the *pros* and *cons*, and concludes his instructive paper thus: Without wishing to prejudice the fate which may be in store for this new operation, and without forgetting the remarkable successes which Lister and others have obtained, we must recognise in recent simple fractures of the patella, that suture of the fragments after free opening of the joint is a method so hazardous that it ought not to be had recourse to in the first instance. On the contrary, in certain old fractures, with a view to remedy severe functional disturbance, it may be tried, but even then the operation is not free from dangers. The author refers also to the influence of atrophy of the quadriceps muscle as a factor in the pathology of loss of use of the limb; and he remarks on the absence of any attempt to prevent or treat it surgically.

The same subject has recently been discussed by Dr. J. L. Little, who describes (*New York Medical Journal*, March 29th) a method which he has practised with success since 1863. The traumatic effusion into the synovial cavity having subsided (aided if necessary by the application of pressure), a posterior splint of two thicknesses of flannel (strengthened in the middle, under the knee, by two extra layers) and plaster of Paris, is made long enough to reach from a little above the ankle to above the middle of the thigh. Above and below the knee joint it should be wide enough to embrace two-thirds of the circumference of the limb, but at the joint it should only just cover the condyles of the femur. The splint is further attached to the limb by a three-inch wide strip of double flannel and plaster encircling it and the limb at each extremity. Having been thus applied, the splint is maintained in position by a *dry* roller bandage firmly applied over all until the plaster has set. When the plaster is firm, the bandage is removed, and two other strips of double flannel, an inch wide, and long enough to overlap on the posterior surface of the splint, are soaked in freshly-mixed plaster, and then tightly applied cross-wise above and below the patella, while the fragments are held in position by an assistant. A dry roller bandage is then applied rapidly with figure-of-eight turns over the strips, and the surgeon then, with thumb and finger of each hand over these coaptation bands, forces the fragments into close approximation and holds them there until the plaster has set. The bandage is then removed, and the dressing is completed by applying a fresh dry roller over the whole length of the limb. The patient may sit up or get about on crutches. The dressing is not a heavy one, and the site of injury can be at any time inspected by merely removing the external bandage; if any displacement of fragments have occurred, it can be corrected by removing the coaptation bands and applying fresh ones. Very satisfactory results—including cases of bony union—appear to have been obtained by this method.

RUPTURE OF BOTH QUADRICEPS EXTENSOR TENDONS.—Two cases of this accident have recently been recorded. In the first case (*New York Medical Journal*, December 29th, 1883), the patient, ten years ago, fell, detaching the quadriceps extensor on the right side from the patella. Six years later he had another fall, when a similar accident occurred on the left side. A year ago the right knee-joint became the seat of acute arthritis, was opened and washed out several times, and subsequently healed. At the present time the quadriceps extensor femoris on either side appears to be quite absent, so that the finger can be thrust deeply behind the upper border of the patella, and rest well in the inter-condyloid notches. On a level surface the patient walks fairly well, and he has very few falls. If the legs are flexed, he cannot extend them at all. The right leg can be extended to 170° and flexed to 75° passively; there is much grating, and the patella is fixed; there are several cicatrices about the knee. The left leg can be flexed and extended passively through normal arcs. The second patient, seventy-two years of age, was recently shown at the New York Surgical Society (*Philadelphia Medical News*, April 12th). He had ruptured both his quadriceps extensors, producing an abrupt depression above the upper margin of the patella on both sides, sharp edges indicating where the aponeuroses had not been ruptured, and furnishing two strong fibrous bands which enabled him to make some extension of the limb at the time of the injury. There was also a good deal of extravasation. The accident was caused by slipping upon a piece of ice, one knee giving way, and the other tendon rupturing almost immediately afterwards. The patient was treated by placing the limb in a straight position; a large amount of effusion took place in one joint, but not in the other. The injury occurred three months before, and the man is able to walk slowly both tendons having united equally well.

TRAUMATIC DETACHMENT OF THE LOWER EPIPHYSIS OF THE FEMUR.—M. Delens, of the St. Antoine Hospital, after analysing the cases of this accident that have been hitherto published, arrived at the following conclusions:—(1.) It has been almost exclusively observed in boys, and especially

between the tenth and eighteenth year. (2.) The detachment is ordinarily proved by forced extension of the limb, whether combined or not with torsion and tearing away. The posterior ligament of the knee-joint plays, in the mechanism of this fracture, a part analogous to that of the anterior ligament of the radio-carpal articulation in fracture of the lesser end of the radius. (3.) The detachment most frequently takes place at a point nearer to the extremity of the diaphysis than that of the epiphysis. It is often accompanied by the separation of a scale from the end of the diaphysis. (4.) It has sometimes been confounded with dislocation of the knee. (5.) Among the primary complications, one of the most frequent and most serious is the perforation of the skin, and the protrusion of the end of the diaphysis. When this cannot be reduced, it should be immediately excised. Primary amputation should be reserved for cases in which there is rupture of the popliteal artery. Secondary amputation is sometimes rendered necessary by sphacelus or other dangerous complications. (6.) Excision of the end of the diaphysis allows of the preservation of the limb, and does not prevent the complete re-establishment of the motion of the joint. The ultimate increase in length of the femur, although strongly influenced is not arrested by the excision.—*Archives Générales*, April.

Statistics of Ear Diseases.—Dr. Bürkner from tables which he has constructed from cases observed by himself, and from numerous statistical reports published by others (making a total of 58,645 cases) arrives at the following conclusions:—(1.) The most frequent causes of diseases of the ear are catching cold, affections of the nose and pharynx, and the existence of acute infectious diseases. (2.) The predisposition to these affections increases from birth to the fortieth year, and diminishes from then to old age. (3.) Men suffer from diseases of the ear more than women in about the proportion of three to two (4.) Of the entire number of cases in about 25 per cent. the outer ear is affected, in 67 per cent. the middle ear, and in 8 per cent. the internal ear. (5.) The left ear is more frequently diseased than the right, in the proportion of five to four. (6.) Acute affections of the middle ear occur seldomer in summer and autumn than in spring and winter. (7.) Of the entire numbers of diseases of the ear treated in the polyclinics (out-patient department), about 53 per cent. are cured, 30 per cent. are relieved, 7 per cent. remain uncured, and 0·3 per cent. prove fatal. Dr. Bürkner points out that the worth of such statistics is much diminished by the fact that the cases are treated at the polyclinic, so that it is difficult to follow the course of a great number of them, as would be expected also from more males than females forming the subject of them. The proportion of cured cannot also be exactly given, for while many aurists regard a case as cured, even when the completely normal hearing-distance has not been restored, the others would only place it amongst the improved.—*Centralblatt für Chirurgie*, March 29th.

Foreign Bodies in the Ear.—A lecture delivered by Dr. Sexton at the Clinic of the New York Eye and Ear Infirmary, in which numerous cases are referred to (*Philadelphia Medical News*, March 1st), contains several useful practical observations. "Foreign bodies," he observes, "are not often met with in the ears of very young infants, unless put in by playmates—a difficult feat, on account of the collapsed state of the canal in these subjects. Older children frequently introduce them themselves. The entrance to the meatus is often, especially in children, naturally contracted by the elastic fold of its posterior border, which comprises that portion of the cartilage forming the bottom of the concha and beginning of the canal. When foreign bodies are slipped beyond this constriction, they are indefinitely retained, since they cannot fall out again of themselves, nor can they be removed by jarring the patient's head. In syringing for their removal, escape at this point is difficult, and should, therefore, be facilitated by drawing back the auricle, and completing the extraction by means of the hook or forceps. Illumination by means of the head-mirror is a *sine quâ non*. There should never be undue haste or precipitation in the efforts at removal. In young and restless children it is quite often necessary to administer an anæsthetic before beginning operative procedures. The operator should first carefully ascertain the exact location of the object, and its size and character; and as to this matter, the statements of the patient or friends should not be implicitly relied on, as they are frequently misleading. Regarding the choice of instruments, Dr. Sexton advised, that when the patient was old enough to keep quiet, and the object was found just within the lumen, the hooked curette was usually alone sufficient; but even in such a case as this, if the body had been started further in on being touched, it was well to direct a small stream of warm water into the canal, well to one side of the stranger, if possible; and this should be quickly followed up until successful—not forgetting that the child must usually be firmly held by a competent assistant. Should the body, however, be found well down in the *cul de sac* and impacted, as is too often the case from previous unsuccessful efforts, syringing may be unavailing, and the foreign-body forceps will often be needed—indeed, they are of the greatest value when the object is impacted anywhere in the canal, since, when held in their bite, very great traction can be made. When the hard, or smooth and hard, nature of the object prevents a secure hold being thus obtained, the hooked curette is the most serviceable instrument; for it can be, in nearly all cases, forced between the object and the walls of the canal, and from its firm hold—the teeth being set so that, on withdrawal, they become fastened, or firmly impinge against the object—effective traction can be made. Of course, when a firmly-impacted body has once been started, efforts should not be relinquished until successful, even though the canal be considerably lacerated, for such wounds are generally found to heal very promptly. When the body lies in contact with the drum-head, it requires great tact and dexterity to avoid injury to that delicate structure; but in the great majority of instances the operation may be safely performed. In these difficult cases of deep impaction, it is often found that the foreign-body forceps will grasp hard and smooth objects more successfully than would be supposed, and patient effort in this direction should not be too quickly relinquished. The surgeon must *under no circumstances try to fix the forceps without distinctly seeing what he is about.* If the parts are moistened with blood, mucous, &c., this should be carefully wiped away before proceeding. Sometimes the bleeding may be checked by light syringing with *hot* water before wiping the parts. Should the operator carelessly poke the forceps about in the neighbourhood of the drum-head in efforts at seizure, he may easily lacerate that membrane.

The Treatment of Hepatitis and Hepatic Abscess.—After pointing out the difficulties of diagnosis of hepatic abscess, and how utterly erroneous are the descriptions given in the text books, Dr. Manson ("China Customs' Medical Reports for 1883") describes his operative treatment. An abscess in the liver, he argues, ought to be treated exactly as an abscess anywhere else would be. The object of the present communication is to show how a free opening may be made into a deep-seated abscess without the danger of profuse hæmorrhage or of setting up peritonitis, and without incurring many other risks that might well be urged against the operation. Having ascertained the presence and site of the abscess, Dr. Manson punctures with a large trocar and cannula; after withdrawing the trocar he passes down the cannula a long stilette, on which, by means of a small eye at one end and a piece of string, he has stretched a piece of perforated indiarubber tubing; whilst inserting this he withdraws the cannula, so that the rubber tube is grasped tightly by the tissues. On cutting the string which keeps this stretched, it tends to rebound towards the fixed end, *i.e.*, towards the abscess cavity; the stilette is next withdrawn, when the wound, both in the liver and abdominal wall, will be found to be securely plugged by the tube. This can then be connected with a bottle to receive the discharge, which at first would be too great to be merely received into the dressings. The whole operation is done under antiseptic precautions, and one of its not least advantages is that it can be done by a man single handed.

Reindeer Tendon as a Ligature.—Dr. Putiloff, of Omsk, in Siberia, reports that he has found the thread made from the tendon of the reindeer, for sewing, in Siberia, a highly useful substance in surgical practice. For this purpose, it is first steeped in ether for 24 hours, and afterwards, for the same time, in a five per cent. carbolic acid solution. Thus prepared, the tendon is found to be stronger than catgut, and as soft as silk, and is completely absorbed in the wound.—*Centralblatt für Chirurgie*, March 22nd.

Coccygodynia.—In exhibiting a carious coccyx which he had removed from a patient who had manifested all the classical symptoms of a very bad coccygodynia, Dr. Goodell referred to two other cases of the mimetic variety of the disease. To one patient, who suffered from very exacting coccygeal symptoms, an operation was at length proposed. As soon as the day and hour were fixed, she lost all pain in the coccyx, and had suffered no return of it during the last six years. Another very obstinate and severe case, which had a traumatic history and which had been treated for a long time unsuccessfully, quickly disappeared under the influence of an exciting family jar.—*New York Medical Journal*, March 15th.

The Orthopædic Surgeon as a Mechanical Engineer.—Dr. Shaffer contends (*New York Medical Journal*, January 26th), that every orthopædic practitioner ought to furnish specific details of every appliance which he requires, and should, if necessary, be able to make it, or at least *know how* to make it. He claims that there is nothing degrading or unprofessional in attending personally to the details of the mechanical department of orthopædic work; and contends that every scientific orthopædist competent to give to his patients the skill which they have a right to demand should become responsible for everything pertaining to the manufacture of the instruments to be used. In direct connection with the New York Orthopædic Dispensary, there is a fully equipped mechanical room in which four or five men are constantly employed in making apparatus directly under the instructions of the surgeons; no apparatus is made without a drawing, and careful measurements — accompanied by actual outlines when necessary—are given with every order; no repairs are executed except by personal instruction of the surgeons. A similar shop, fitted with steam power, has been established in connection with the University Hospital at Philadelphia. It is stated that the entire cost of this building did not exceed two thousand dollars, and that it is now almost self-sustaining—actual cost of production only being charged to those patients who are able to pay for it.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Friday, May 9th, 1884.

Sir Andrew Clark, Bart., M.D., President, in the Chair.

Intestinal Obstruction (by a Diverticulum) successfully treated by operation.

The following is an abstract of the paper by Mr. Clutton:—A boy, aged 10, was brought to Mr. Clutton's notice by Dr. Powis, of Greenwich. He had had several other attacks of a similar kind, but lasting only two or three days, and always terminating with a copious evacuation from the bowels after enemata. On this occasion he was taken ill suddenly at the seaside with vomiting, and great pain in abdomen. He was brought home to Greenwich on the third day, and as treatment by enemata and opium proved of no avail, Mr. Clutton was asked by Dr. Powis, on the fourth day of the illness, if operation would be likely to afford him relief. He was at once transferred to St. Thomas's Home, where, after the administration of an anæsthetic, the abdomen was opened. A collapsed portion of bowel was soon found, and on bringing it to the surface a tight ring-like cord could be felt and seen to be the cause of strangulation. This band was clamped by two pairs of forceps and divided, each end was then ligatured with catgut and the forceps removed. The bowel was found after the division of the constricting band to have been set free from strangulation. It was not thought desirable to make more than a cursory examination for the origin of the band causing the obstruction as the boy was much collapsed before the operation commenced. The two catgut ligatures formed the means of recognising the original position of the now divided band. One of these ligatures was situated at the extreme point of a diverticulum two inches in length, and the other was placed upon the wall of the same loop of intestine at a distance of about six inches. A portion of bowel of about three inches in length between these two points of attachment was the part strangulated, and was of an extremely dark colour with a deep sulcus at each side. The boy made an uninterrupted recovery and left the hospital on September 12th. The explanation of the condition found in the abdomen seemed to Mr. Clutton to be as follows:—The vitelline duct had been obliterated at the umbilicus, and set free from the abdominal wall, but remaining patent towards the ileum, the lower end had become a pouch-like diverticulum from the intestine. This diverticulum terminating in a pointed extremity or cord—part also of the vitelline duct which had been obliterated—had remained floating about among the intestines till it became attached, as we have seen, to the bowel in contact with it. The gut between the two points of attachment had slipped beneath the cord which united them, and being unable to extricate itself had become strangulated.

Dr. Coupland congratulated Mr. Clutton on the success of his case. Of several operations which he had himself seen not one had been successful, but he thought that the strength of the patient mainly determined the issue of the case. This form of strangulation under Meckel's diverticulum was the most common and he had seen many such cases. He quoted one in which a distinct depression of the umbilicus had been caused by the attachment of the band to it. Such depression might occasionally assist the diagnosis. In another case he had made a *post-mortem* examination and had found that a portion of bowel had passed through the mesentery of such a diverticulum.

Mr. F. Treves remarked that Perrot had recorded twenty-nine cases of internal strangulation, only seven of which were caused by Meckel's diverticulum. In the cases which he had himself collected the proportion was about the same. He thought that this must be regarded as the most acute form of strangulation; cases did not often survive the fourth day. The fact that the strangulating medium was itself bowel might be held to account in some measure for the extreme nervous disturbance produced. In cases where the diverticulum was not attached to the umbilicus it was generally found to be united to the mesentery. He considered that a history of previous attacks of obstruction was not of much importance in the diagnosis. With regard to the pain, he believed that it was generally continuous in cases where the strangulation was complete; as diagnostic of the seat of obstruction, however, it was of no value, being generally localised in the neighbourhood of the umbilicus. He thought that further clinical details would be of interest, especially with respect to the relation of the pain to the vomiting. Mr. Clutton's case was probably the first successful operation on record in which a tubular constricting band had been divided.

Dr. Mahomed thought that, although such cases were well-known, there were many points upon which discussion might throw additional light. He felt certain, from his own

experience, that paroxysmal pain was not of necessity indicative of partial stricture. He thought extreme distension generally pointed to strangulation of the large intestine. He preferred to make the incision to the outer side of the right rectus, instead of in the median line.

Mr. TREVES explained that he had examined the reports of 50 cases of complete obstruction, and in only five had the pain been paroxysmal.

Mr. C. J. SYMONDS asked for further information with respect to the seat of incision. In the cases in which he had operated with Dr. Mahomed, he had made the opening at the point of greatest distension. Was such a rule a safe guide? He himself preferred the middle line, thinking that bands were more commonly found about the level of the iliac crests. He referred to the high mortality in these cases which he considered might be reduced by more immediate treatment, as in cases of hernia.

Mr. H. MORRIS referred to a case operated upon directly after admission, the incision being made in the middle line. The patient was the subject of double inguinal hernia. The sac on one side containing the nipped intestine was found to be displaced. When the large intestine was strangulated, the cæcum was generally the seat of the greatest amount of distension. He mentioned the advantage of colotomy, in cases where the seat of strangulation was doubtful, and related a case in which much relief had been given by evacuation of fæces by this means, although the presence of a second strangulation led to a fatal result.

Mr. CLUTTON, in reply, recapitulated the chief points in the clinical history of the case. He thought that, even with complete strangulation, life might be prolonged beyond the fourth day, and mentioned an illustrative case which proved fatal on the ninth. In the present instance the constricting band was a solid fibrous cord, and not tubular. He would oppose the practice of opening the abdomen anywhere than in the middle line, which, he thought, was by far the best situation, more especially in doubtful cases.

The Treatment of Fractured Patella.

Mr. CHRISTOPHER HEATH read a paper, of which the following is an abstract, in fulfilment of his promise at an early meeting of the Society, to produce patients treated immediately after the accident by plaster of Paris. He gave Mr. Hutchinson the credit of first combating the old teaching that separation of the fragments depended on muscular action, and agreed with him in believing that it was the fluid in the joint which was the difficulty. Mr. Heath proposed to get rid of the fluid by aspiration, and had never seen any bad result from the practice, but preferred, when possible, to prevent effusion by at once enclosing the joint in plaster of Paris. This required renewal in about six weeks, and at the end of three months a leathern splint was applied to the knee and thigh so as to control the action of the extensor when the patient was walking. Two women and a man were shown, in all of whom the plaster was applied within an hour of the accident, with very good results as to short fibrous union.

Mr. HENRY MORRIS had treated a case of fractured patella on November 7th, 1883, in which a very wide separation had taken place, the upper fragment being drawn up towards the thigh. The patient had been able, however, to bring it down to some extent by kneading. He thought that the laceration of the fibrous capsule of the joint had a great deal of influence in permitting this wide separation. He had often proved the fact on the dead body, and did not himself think that the fluid effusion into the joint could possibly be the sole cause. At the Middlesex Hospital the cases were treated by elastic traction upon the upper fragment. He showed the splint employed after six weeks' treatment, its special advantages being that it allowed of a graduated movement of flexion, whilst still supporting the limb, and preventing any danger of accidental twist or strain. In his own two cases there was hardly any displacement. He did not, however, believe that true bony union had taken place.

Dr. JULIUS ALTHAUS enquired whether these cases exhibited the knee-jerk phenomenon.

At the suggestion of the PRESIDENT, he examined the cases present, and reported that the phenomenon was present in all the cases.

Mr. R. W. PARKER thought that, whatever the cause of the separation, there could be no doubt that effusion into the joint was the cause of the difficulty of bringing down the upper fragment. The practice of tapping the joint was until lately regarded in Paris as unjustifiable, a view which was not in accord with Mr. Heath's teaching of aspiration as a routine procedure.

Mr. C. J. SYMONDS asked what amount of fluid should be removed; whether it was any good to remove small quantities. In one very successful case he had applied Martin's rubber bandage, before fixing the joint in plaster of Paris.

Mr. G. R. TURNER had examined many museum specimens of fractured patella and had only seen one in which, with a transverse fracture, there was complete bony union, although it was more common in the starred fractures. In some cases with complete separation of the fragments, but with intact capsule, the joint remained good and useful. He would like to see these cases a year later, when they had left off artificial supports, believing that separation would be sure to take place, as in all other instances of fibrous union.

Mr. R. J. GODLEE thought that wiring alone could give a really perfect result. Portions of the capsule or of fibrous tissue frequently became squeezed between the fragments and prevented union. No operation could be justifiable, however, unless the operator was confident of his own powers of maintaining complete antiseptic precautions.

Mr. CHRISTOPHER HEATH did not think that Mr. Morris's case was conclusive as to the continued contraction of the muscle. He now caused all his cases to be put up in plaster of Paris when quite recent, and hence aspiration was rarely necessary. From three to four drachms was generally enough to remove.

Hydrocephalus, probably of old standing, followed by Insanity and Death.

Dr. WHIPHAM read notes of the following case:—The patient, aged 39, was one of twins, his brother having died in infancy of effusion on the brain. In early years the subject of the communication had been uncertain in temper, and had occasionally squinted. After 12 years of age he enjoyed remarkably good health; his intellectual capacity was above the average; he was well informed on most subjects, and fond of exercise. He had suffered in early manhood from a soft sore, but never had syphilis. On October 7th, 1882, he consulted Dr. Whipham, because "he had been mad." It then appeared from inquiries through his wife and friends, that he had been for eighteen months, from time to time, strange in manner and irritable, and that he often sat by himself at his club, muttering; that in conversation he often lost the thread of his discourse; that he had written inexplicable letters to a relative and to a friend. Of late he had become very drowsy, and even went to sleep occasionally while at meals. His memory had been failing for eight months or so. He had been a regular, but not excessive, smoker. At the date above mentioned his expression of face was vacant, and, unless questioned, he stared vacantly at space. His answers were inaccurate, and he had one or two delusions. His gait was steady, his grasp feeble, his special senses natural. He became more and more captious and irritable, and his usual reading was distasteful. Once or twice he was obstinate and somewhat violent in the streets. By Dr. Blandford's advice, he went to Folkestone for change, but derived no marked benefit. On one occasion he started for a walk by himself in the middle of the day, and returned, without being able to give any account of himself, at nearly midnight. On his return he became morose and sullen rather than violent, and was eventually sent to

Munster House. Soon after his arrival it was noticed one day that the left pupil was larger than the right, and he had a fit during dinner. Ten days later he was again violent and noisy, wet and dirty. Two days before his death, when walking with the support of an attendant, he suddenly fell headlong to the ground, sustaining no injury save an abrasion of the nose. The patient died early on December 28, 1882, and on the morning of the previous day had been excited and very noisy. Subsequently he became unconscious for some hours. At 7.30 p.m. he recovered, and was more rational than at any time since October 10. This condition lasted for a quarter of a hour, when he again became drowsy, and at last unconscious till his death. At the autopsy the ventricles of the brain were so distended as to contain about three-quarters of a pint of fluid. The dura mater was adherent generally to the skull-cap. No other lesion of the brain was found. Dr. Blandford, who was called in consultation, rather inclined to the diagnosis of general paralysis, basing his opinion on the elation, incoherence of ideas, and inability to concentrate his attention. Dr. Savage, in the *Journal of Mental Science*, July, 1880, records a case in which great dilatation of the ventricles was found in a female, aged 35, who was insane for eight months before her death. In this case, however, there was the complication of granular kidneys. In the case before the Society, all the symptoms of general paralysis were not present, and a certain diagnosis was not made. Elation certainly existed at one time, but only lasted for a day or two, and the gait, save on one or two occasions soon after the attack, was remarkably steady. In the absence of any evidence of other disease, the symptoms must be referred to the hydrocephalus, presumably of long standing.

Dr. Blandford remarked that in this case there had been many features present which were characteristic of general paralysis of the insane, and he had expected that an outbreak would take place, but a condition of stupor seemed to have taken its place, and showed remissions from time to time very difficult to account for.

Dr. Althaus enquired if there had been a history of syphilis in the case.

Mr. R. W. Parker asked if there had been atrophy of choroid.

Dr. Whipham replied that there had been no reason to suspect syphilis. The eyes had not been examined by the ophthalmoscope.

The President drew the attention of the Society to the fact that the next meeting was the last of the session, and that several papers still remained to be read. He suggested that an additional meeting might be held, but left the point for decision at the next meeting.

The following living specimens were exhibited :—

Cases of Fractured Patella.

By Mr. Christopher Heath, and Mr Henry Morris.

Two Cases of Rupture of Brachial Plexus.

By Mr. C. J. Symonds, and Mr. Davies Colley.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, May 13th, 1884.

George Johnson, M.D., F.R.S., President, in the Chair.

A Pelvic and Parietal Tumour of the Abdomen. Removal by Operation. Recovery.

Mr. Gant related the particulars of a case in which a tumour grew from the ileum, and lay between the muscles of the abdominal wall. The question of diagnosis had reference principally to the distinctive characters of a tumour thus situated, and an ovarian or a uterine tumour; but the differentiation between a pelvic fibroma, as in this case, and other forms of pelvic tumour was also noticed, and the circumstances which indicated its parietal relations were considered. The operation was then described, including the precise relations of the tumour, and the antiseptic dressing employed. The descriptive and histological characters of the morbid growth were specified. Some references to similar cases were appended, but they were rare in the records of surgery. All such cases agreed in two particulars: they had occurred only in women who had borne children; and that, whether fibrous or apparently recurrent fibroid, the growth had not returned after removal by operation. The increasing and sometimes rapid growth of these pelvic and parietal tumours demanded surgical interference; but the liability of opening the peritonæum, accidentally or unavoidably, and the almost certain result of a ventral hernia through the weakened abdominal wall, might so far deter the surgeon from having recourse to operation were it not for the assurance that he had to deal with a tumour which had hitherto proved to be non-recurrent.

Mr. Barwell congratulated Mr. Gant on the success of the operation. In tumours which arose from the inner parts of the pelvis, it was difficult to say whether they were malignant or innocent. Hence the reluctance with which surgeons interfered. The non-appearance of a ventral hernia was probably partly explained by the fact that the tumour developed outside the transversalis fascia, which covers the peritonæum in this situation.

Mr. Gant, in reply, thought that surgical interference with cases of malignant disease of this site should be undertaken with great precaution. The hard and painless character, with slowness of growth of his tumour, led him to think that the new growth was innocent. In the operation it was important not to "button-hole" the peritonæum.

An Easy and Safe Method of Sounding for Impacted Gall-Stones.

A paper on this subject was communicated by Dr. George Harley. The method recommended in the paper for indubitably ascertaining the existence of impacted biliary calculi was illustrated by the narration of a case in which it was successfully performed in the following wise :—the patient, a lady aged 36, who had been (under the care of Dr. Diver) for many weeks suffering from the signs and symptoms of obstructed bile duct, was placed under an anæsthetic. Dr. George Harley inserted a six-inch long French exploring trocar midway between the umbilicus and margin of the liver an inch and a half to the right of the median line. Its point being pushed upwards and backwards in the direction of the common bile duct, no hard substance was met with, on the stilette being withdrawn ascitic fluid came away, and the cannula could be moved freely in all directions. The instrument was withdrawn and reinserted an inch higher up, and about two inches to the right of the umbilicus. On pushing it in the same direction as before, to the depth of six inches, its point struck into a hard substance, presumed to be a biliary calculus. It was endeavoured to estimate the size of the stone by pressing the end of the cannula without the stilette firmly against the hard substance, and moving the point of the instrument all round it. The inference was that the stone was the size of a hazel-nut. The punctures were closed by means of sticking plaster, and the abdomen bandaged. The signs of obstruction now began rapidly to disappear, and it was supposed that the operation had caused the stone to change its position in the duct, and had thus enabled it to pass along into the duodenum. Convalescence at once set in, but was of short duration, for an attack of enteritis supervened, followed by peritonitis, and the patient succumbed

twenty-seven days after the sounding, and twenty-four after the stone had evidently left the duct. At the autopsy the thirteen calculi shown to the Society were found still in the gall-bladder, the longest being an inch in length, the next the size of a hazel-nut, the remainder all much smaller. The facets on the opposite ends of the large calculus showed that another stone, the size of a hazel-nut, must have existed, but come away. The paper ended with the following conclusions:—(*a*) That the presence of an impacted gall-stone may be readily as well as safely ascertained in the way described. (*b*) That not only the position, but even the size and shape of an impacted biliary calculus may be instrumentally ascertained. (*c*) That a knowledge of these facts may possibly induce surgeons to undertake the earlier artificial removal of dangerously impacted gall-stones than heretofore; an operation which the author of the paper thought ought to be, under ordinary circumstances, no more hazardous to the life of the patient than the operation of lithotomy. He believed that the fatality that had hitherto attended the operation had been almost entirely due to the fact of its having been delayed until the exhaustion of the patient precluded the possibility of recovery.

The PRESIDENT said the paper had opened up some very interesting questions. A case was mentioned in which a stricture was found, though a calculus had been diagnosed. He would like to be sure that bile was innocuous in the peritonæal cavity, but the evidence adduced on this point was, up to the present, insufficient.

Mr. F. B. JESSETT said that Mr. Lawson Tait had reported four cases of successful removal of gall-stones from the gall-bladder by operation. He questioned whether it would not be better to make an exploratory abdominal incision, which need not be large, and might be made parallel to and a little below the margin of the ribs. The stitching of the divided walls of the gall-bladder to the edges of the abdominal incision had been advocated by Mr. Lawson Tait. This would prevent bile gravitating into the peritonæum.

Mr. GANT paralleled the operation with that of nephrolithotomy, the main difference being that urine could not escape into the peritonæum. He was acquainted with the fact of peritonitis being the result of the extravasation of bile. Would it not be safe first to empty the gall-bladder by means of an aspirating syringe?

Sir WILLIAM MACCORMAC asked how Dr. Harley could speak of the operation as a safe one, seeing that peritonitis followed the procedure in the case he had related. He could not help thinking that the employment of an instrument blindly moving in the abdomen was dangerous. He preferred an exploratory incision such as was now made for so many morbid conditions within the abdomen.

Dr. DYCE DUCKWORTH thought the discussion had somewhat wandered from the subject of the paper. The method of sounding was not, in his opinion, an easy or safe one. The operation was, he considered, one of extreme difficulty. He wished to know what further procedure was necessary after the operator had supposed that he had ascertained the presence of a biliary calculus. Gall-stones were sometimes impacted very tightly in the gall-duct. A clumsy hand working in the dark in such an important region was very likely to do great mischief.

Dr. O'CONNOR asked Dr. Harley whether the liver was enlarged, how large the gall-bladder was, and whether there had been any severe paroxysmal pain. He did not think the method was a safe or an easy one.

Mr. BARWELL said there was much dislike on the part of patients to be subjected to an incision, unless they could be promised beforehand that something would be found. In this regard Dr. Harley's method might be looked upon as a valuable preliminary. He suggested that the fundus of the gall-bladder should first of all be explored. If calculi be detected there, Dr. Harley's instrument might be used as a guide in the performance of a subsequent operation. The mode of exploration was, however, regarded as of possible future value. The assumption that bile was innocuous in the peritonæal cavity was very hazardous. Needles might penetrate the human heart without ending fatally, as Mr. George Callender had shown.

Dr. C. J. HARE enquired as to the site of impaction of the gall-stones. Was it in the gall-bladder itself or in the biliary duct? Sometimes the gall-bladder was distended with fluid; at others it was empty. The gall-bladder was not always at an equal depth from the abdominal surface. The instrument had only given information of the existence of one gall-stone, when there were so many others. How was this? He looked with fear and trembling on the method.

Dr. GEORGE HARLEY, in reply, began by saying that very few medical men knew much of gall-stones, either in England or elsewhere. Erroneous notions concerning gall-stones were alarmingly prevalent. He recommended the perusal of M. Cyr's recent work. The difficulties of diagnosis were spoken of: cancer, stricture, ulceration of the duodenum, and other conditions sometimes exactly simulated the impaction of gall-stones. Most of the organs of the body, including the intestines and urinary bladder, had been punctured with a fine instrument without evil result. He emphasised the fact that this patient greatly improved after the surgical exploration. Sickness and vomiting were the invariable signs of impaction of a gall-stone in the gall-duct. Undoubtedly there was risk in exploring by the method advocated, but then it must be remembered that danger existed in almost every surgical procedure.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE II.

THREE SYSTEMS OF SEWAGE DISPOSAL.

THERE are three typical exemplifications of processes of sewage disposal at the Exhibition. In that adopted by the Manchester Corporation, the refuse matter derived from human beings, animals, vegetable matters, dust, &c., is all carted away to one place and destroyed, or manufactured into useful products. In Moule's earth system there is no manufacture, but simply conservation for a limited time, and restoration direct to the soil of that which has been derived from the soil; and, lastly, there is an exhibit of the A B C process carried out at Aylesbury. Each of these exhibits is worthy of special notice.

The Manchester System.

Manchester, a city of over 34,000 inhabitants, has for the past ten years adopted a "pail system," keeping all refuse matters as far as practicable out of the sewers, and has been able to manufacture a saleable manure and certain other products. Water-closets are of course excluded, but the excreta are received into a pail, and mixed with fine ashes; this mixture is effected by the ashes being shot against a sort of sifter, the fine ash-dust falling into the pail, the coarse into a special receptacle. The pail is of a special construction, it is made of steel, and provided with a caoutchouc rim, on which a cover is securely and hermetically clamped by a simple mechanical arrangement; the pails are of the capacity of ten gallons, and are removed daily or at longer intervals, according to circumstances, in a collecting van, which has two compartments, one for the pails, another for house refuse. The following table gives an idea of the quantities annually dealt with by the Corporation:—

	Tons
Fish, bones, dead animals—dogs, cats, &c.—boots, hats, &c.	137
Slaughter house refuse	1,295
Human excreta	31,817
	33,249

Vegetable matters—	
Cabbages, potatoes, straw, oil cloth, matting and brushes	38
Wet and dry cinders	36,210
Domestic dust	11,932
Glass and stone bottles, broken pots, flags, mortar and brickbats	480
Rags, paper, iron, wire, and tin	110
Total	82,019

These several matters are dealt with as follows:—The animal matters are deprived of their fat, which is worked up into soap, grease, &c., and treated with sulphuric acid to fix the ammonia; then the dried mass is broken up, powdered, and sold to the farmers as manure. The excreta are treated very similarly.

A model of the machines by which the drying and grinding is effected is exhibited, and great ingenuity has been displayed in its construction.

The cinders are used in the furnace fires, in order to effect the evaporations. The rags, paper, iron, wire and tin, are sifted out and sold. Some of the refuse is made into bricks, mortar and concrete.

The manure, the bricks, and samples of all the manufactured products are in the exhibit.

Manchester has adopted this system for ten years, and is satisfied with it, but the death-rate is still high, fluctuating between 24 and 25 per 1,000. It is often said that this high death-rate is due to Manchester being mainly a city of cottages; but this explanation can hardly be the correct one, for such a death-rate is slightly higher than that of the majority of the London tenement streets, so that if the disposal of refuse has so much to do with the mortality, as is generally believed, Manchester will not compare with towns in which the water carriage system is in force; that the old death-rate was 33 per 1,000 is a fallacious argument in favour of the new system, for at that time there were 60,000 cesspools, enough to have made a sufficient quantity of mephitic vapour to have infected a third of the population with all kinds of pythogenic maladies.

Moule's Earth Closets.

Moule's earth closets, Class XXIII. 535, have been lately improved, and as now made are in action automatic; a hopper is charged with earth, and by either pulling a handle or by the mere act of rising, a certain quantity of earth is thrown into the pail. In the same exhibit may be seen the model of an upstairs closet; by a lift arrangement earth can be conveyed to the closet from behind, so that it is unnecessary for the requisite supply of earth to be conveyed up the stairs; in the same way the pail or truck receiving the excreta may be removed.

The system as applied to schools is exemplified by means of a model. There has long been little difference of opinion that the earth system is a very cleanly good system for isolated houses in the country, or small communities; it has been in use at the Charter House School, Godalming, for some years; at the Board Schools, Sutton; at New College, Oxford, and at Girton College, Cambridge, and it appears to meet with the approval of the managers of these establishments.

The A B C Process.

In a detached building, the Native Guano Company exhibit the A B C Process for the disposal of sewage. This process has been in operation at Aylesbury for eight years, at a net cost to the town of 250*l.* a year. The town of Aylesbury differs in regard to its sewage, from other towns of a similar size in the enormous quantities of waste liquid from its tanneries. The sewage is all concentrated into one point, is pumped into a reservoir, is mixed there with blood, charcoal and clay, and then precipitated with sulphate of alumina; the precipitate is allowed to settle completely, and the supernatant fluid, which is perfectly colourless, is supposed to be in a condition to flow into a river without polluting it. The precipitate is dried and worked up into a saleable manure.

The exhibit showing these details is a very complete one, containing working models of the whole process in action; models of the works at Aylesbury, samples of the manure, and of vegetables grown on soil fertilised by the manure.

OBITUARY.

ANDREW WHYTE BARCLAY, M.D. Cantab., M.D. Edin., F.R.C.P., Lond.

Dr. Andrew Whyte Barclay, whose death, after a very short illness, at the age of 66 years, we have briefly noticed, was a scion of an old Scotch family; and, after receiving a good general education, became a student at the famous Medical School of the University of Edinburgh. He took the degree of M.D. there in 1839; but having been led by circumstances and an honourable ambition to settle as a physician in London, and finding that his Scottish degree would not, in those days, easily open fully to him the portals of the Royal College of Physicians of London, he entered as a student at Cambridge, and took the medical degrees granted by that University. He was elected to the Fellowship of the London College of Physicians in 1851; and in the following year he took the M.D. degree of Cambridge. He was for some years Physician, and finally Consulting Physician to the Chelsea, Belgravia, and Brompton Dispensary; and having been elected on the Staff of St. George's Hospital, he faithfully and assiduously discharged the duties of Assistant Physician, and full Physician till a year or so ago, when he retired, and was elected Consulting Physician to the Hospital. He was also Lecturer on the Principles and Practice of Medicine in the Medical School of the Hospital. Dr. Barclay was a highly educated physician, an acute and close observer, and a most honourable gentleman and trusty colleague; and he possessed social and mental gifts that endeared him to a large circle of friends; but he did not possess all the qualities that are necessary to command large and popular success as a practitioner. The profession in London showed their appreciation of his high character as a physician by electing him President of the Royal Medical and Chirurgical Society; and he did good service to the public, not only as Physician to St. George's Hospital, but also as Medical Officer of Health for Chelsea, an appointment which he held till the day of his death. He served the College of Physicians well and faithfully for several years in the capacities of Councillor, Examiner, and Censor; and only a few months before his death had been elected to the dignity of Treasurer to the College. He was not a large contributor to the literature of the profession, but he was author of works on "The Progress of Sanitary Measures and Preventive Medicine"; on "Medical Errors," and on "Gout and Rheumatism in relation to Diseases of the Heart;" and he contributed to the Transactions of the Medical and Chirurgical Society, vols. xxxi. and xxxv., papers on "Statistics of Valvular Disease of the Heart"; besides papers to some of the Medical Journals. He was best known, however, by his "Manual of Medical Diagnosis," which was first published in 1857, and attained the honour of a third edition.

GENERAL CORRESPONDENCE.

THE APPEAL OF THE APOTHECARIES.

[To the Editor of the Medical Times.]

Sir,—I have read with extreme regret your leading article, entitled "The Appeal of the Apothecaries," in which you have done a considerable amount of injustice to the Society of Apothecaries, and through them to the ten thousand licentiates. I trust, therefore, you will give a prominent place in your next number to the few remarks I am about to make.

The Society of Apothecaries is one of the City Companies, and is governed, as the others are, by a body called the Court of Assistants, the members of which are elected from the Liverymen (in the case of the Apothecaries, mainly by seniority), the body of the Society consisting of

about 350 members, who are nearly all general medical practitioners, and become members by patrimony, apprenticeship, or purchase.

The Society was constituted an examining body in the Art and Science of Medicine by the Act of 1815 in consequence of the refusal of the then College of Physicians to examine general practitioners as to their fitness to practice medicine, and in that expression lies the gist of the whole matter, and from it arises the question, what does such fitness consist in? Without, however, attempting to answer that question, I will ask, who so fit to ascertain the fitness of the general practitioner to practice medicine as the general practitioner himself? Consequently I believe that the great merit of the Society of Apothecaries as an examining body consisted in the past in the fact that a considerable number of the examiners were general practitioners, and consists in the present in the fact that they are still represented.

You say that a score of old general practitioners should not have the privilege of seating a member in perpetuity on the Board which is to direct the medical study of the future. I appeal to the constitution of the Court of Examiners of the Society of Apothecaries, both past and present, as good evidence that that Society *should* have a voice in the direction of the medical education of the future. Were not Druitt, Corfe, Semple, and Webb, and many others who might be mentioned, fit and proper persons to have such a voice? And are not Randall, Savage, Withers Moore, Burgess, Thorowgood, Carpenter, and all the other members of the present Court of Examiners fit and proper persons to have a voice?

Whatever the examinations of the future may be, the element of fitness to *practice* medicine and surgery must be steadily kept in view, and if the general practitioner is to be excluded from all voice in those examinations, I predict that the minimum examination of the future will satisfy neither the profession nor the public, and that gradually a new class of practitioner will arise, recruited from the ranks of the pharmaceutists, who will gradually elbow out the present general practitioner.

By all means let the examinations for the Membership of the College of Physicians, the Fellowship of the College of Surgeons, and of Graduates of the Universities be conducted by pures and specialists, and on the most scientific lines, but do let the minimum examination of the general practitioner be conducted by practical men and on practical lines. That such has hitherto been the aim of the Society of Apothecaries through their Court of Examiners, and I think not without success, is my firm belief.

Let me, in conclusion, state that the Society of Apothecaries does not benefit pecuniarily by their examinations, and that the Court of Examiners is paid a fixed sum, without reference to the numbers passed or rejected.

I remain, Sir, yours faithfully,
HENRY BULLOCK, F.R.C.S., M. & L. S.A.,
Undergraduate (1st M. B.) London, late Member of the Court of Examiners of the Society of Apothecaries.

P.S.—I may state that I have written the above on my own responsibility, and without communication with any other member of the Society.

HYDRO- AND PYO-SALPINX.

[To the Editor of the Medical Times.]

SIR,—It is a very difficult thing for me to express adequately my obligation to Dr. J. Kingston Fowler, for his contribution to the pathology of these interesting diseases. When I was asked by Dr. Horrocks, at the Obstetrical Society, how it was that I came across so many of these cases, and there were none found at Guy's, I had to answer to the effect that they did not look properly for them. From me this was, as a matter of course, not regarded as a satisfactory reply, but when the answer comes as emphatically as it has done from Middlesex and St. George's Hospitals, doubtless it will be regarded as complete.

It is a very curious thing, that though I have challenged discussion on this subject over and over again, without the result of getting anybody to tread on the tails of my coat, there are constantly being repeated to me all sorts of insinuations made behind my back. Once more I shall bring up the whole subject by a paper at the Medical Society, early next session, when I trust it will be convenient for my sceptical critics to attend.

From Dr. Fowler's paper it is perfectly clear that I have under-estimated the danger of pyo-salpinx, as in his list in eight out of fifteen cases the state of the tubes was the immediate cause of death.

Only one point alluded to by Dr. Kingston Fowler need be referred to at present, and that is, that I do not find that any kind of adhesion, however extensive, new or old, prevents me now from completely removing the tubes. This of course is the result of long and frequent practice, as I often complete operations now that would have been unfinished had they occurred in the earlier years of my practice. Only yesterday a case went hence to London, in which I had to remove both tubes, distended with old cheesy pus, the cause of years of ill-health and suffering, both tubes being densely adherent to everything. In removing the left tube I tore a hole in the rectum, and of course felt certain that I had killed my patient. But the drainage tube has saved her, and the wound is nearly healed, no fæces passing now. In one other case we found a fistula remaining, but it will close in time as others have done. With all this terrible work the mortality remains under 2 per cent., and therefore I am unwilling to join in what Dr. Playfair regards as a safe *via media*, a mortality of 25 per cent.

I may here just mention that, as Dr. Playfair's cases were not instances of hydro- or pyo-salpinx, they were not pertinent to the discussion. It is wholly unreasonable to mix up operations for removing the appendages for bleeding myoma, cases of Battey's operation with operations for hydro- and pyo-salpinx. The principles and details of the operations are as distinct as those of lithotomy and cleft palate.

The objection raised by Dr. Routh, that these operations unsex the patient, has been met so frequently that I am astounded to see it appear again. It is wholly untrue, and even if it were true, I venture to say that any man who would refuse to grant his wife relief from the risks and agonies of pyo-salpinx, because she would no longer gratify his lust, would deserve a name I do not choose to write.

I am, &c.,
LAWSON TAIT.

Birmingham, May 10th, 1884.

[We quite agree in thinking the objection that the operation "unsexes" the patient, an absurd one.

ED. *Medical Times.*]

INVENTIONS AND IMPROVEMENTS.

MELLIN'S FOOD FOR INFANTS AND INVALIDS.

THIS food has for years been favourably known to the profession, and been used with the best success in cases of infantile dyspepsia, in which less thoroughly malted foods were found to disagree. The secret of its success is its complete solubility. The food forms, when treated with water, a fairly clear solution, very pleasant to the taste, and a recent analysis by Mr. Wigner shows that nearly 87 per cent. of it consists of dextrose, dextrine, and maltose, soluble in cold water, while 5·43 per cent. consists of albuminoid matters. We have found Mellin's food, in all but a few cases, well borne by infants at all ages. In the earlier months, and in the case of very delicate children, it should be commenced cautiously, and the quantity gradually increased. When given in this way, it will be frequently found to serve not only as an additional element in the food supply, but also to assist in the digestion of the other elements of the dietary.

BING'S SOLUBLE ESSENCES OF GINGER AND LEMON.

Messrs. Bing & Son, of Canterbury, have sent us samples of their soluble essences of ginger and lemon, which are largely used by them in the preparation of effervescent drinks. The essence of ginger is a clear bright preparation, with the true ginger aroma, and has been certified by competent analysts to be prepared from ginger of good quality, and to be free from any adulteration with capsicum or other deleterious principles. It contains mere traces of resinous matter, and is in consequence very soluble in water. The same may be said of the lemon essence, which is free from adulteration and completely soluble in water charged with carbonic acid gas. The beverages prepared by Messrs. Bing from these essences are, as might be expected from the results of the analyses, clean-tasting and palatable.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners on the 8th instant, and, when eligible, will be admitted to the pass-examination, viz.:—Messrs. H. A. Pope and P. H. Hensley, students of King's College Hospital; C. S. B. Cox, H. A. Sansom, and Leonard Wilde, of St. Thomas' Hospital; Cyrus Legg, of Guy's Hospital; E. P. France and H. E. L. Canney, of University College Hospital; F. W. Ord, of the Glasgow School; E. W. Crossley, of St. Bartholomew's Hospital; W. G. Pridmore, of the Middlesex Hospital; and H. W. Scratchley, of St. Mary's Hospital. Four candidates having failed to acquit themselves to the satisfaction of the Board of Examiners were referred to their anatomical and physiological studies for three months, and one for six months. The following gentlemen passed on the 9th instant, viz.:—Messrs. W. L. Woolcombe, W. W. L. M'Lean, W. R. Duncker, A. J. Bennett, C. M. Hill, and F. G. A. Burns, of St. Bartholomew's Hospital; F. R. Farmer and William Bett, of Guy's Hospital; A. C. Dutt, C. J. Stanley, and Edward Somerset, of King's College Hospital; H. H. Mack and H. C. F. Crane, of the London Hospital; A. H. Vernon, of St. George's Hospital; A. P. Luff, of St. Mary's Hospital; Frank Savery, of University College Hospital; and W. W. Bell, of the Westminster Hospital. Six candidates were referred for three months, and one for six months. The following gentlemen passed on the 12th instant, viz.:—Messrs. J. O. Jones, F. S. Arnold, A. L. Morgan, Ernest Barrett, and P. J. F. Lush, of St. Bartholomew's Hospital; S. F. Holloway, of Guy's Hospital; T. W. M. Longmore, C. R. Blakiston, and J. M. Rees, of King's College Hospital; C. H. Cosens, F. G. Connolly, and W. T. Mould, of the London Hospital; E. D. Shirtleff, of St. Thomas' Hospital; P. L. M. C. Pound and R. F. Reading, of the Middlesex Hospital; and F. S. Lambert, of the Westminster Hospital. Seven candidates were referred for three months. The following gentlemen passed on the 13th instant, viz.:—Messrs. A. W. Laing, F. G. T. Fox, E. J. Nixon, and E. G. Cook, of St. Bartholomew's Hospital; F. B. Morse, H. W. Rickards, K. N. Bahadhurji, and E. B. Randall, of University College Hospital; George Murray, of St. Mary's Hospital; J. D. Ballance and Henry Hudson, of St. Thomas' Hospital; F. P. Sarjant, of Guy's Hospital; Alfred Darlow and T. N. Greeves, of King's College Hospital; A. H. Barker, of St. George's Hospital; James Moore and Percival Smith, of the London Hospital. Six candidates were referred for three months, and one for six months. The following gentlemen passed on the 14th instant, viz.:—Messrs. G. P. Brownlow, C. B. Pym, and Thomas Pye, students of St. Bartholomew's Hospital; A. B. M. Howard and T. A. Brice, of King's College Hospital; J. C. Morgan of the London Hospital; P. C. E. D'Erf-Wheeler, of St. Thomas' Hospital; H. F. Herring and E. F. Bour, of University College Hospital; W. N. Risdon and J. A. Wheeler, of Guy's Hospital; Charles Batchelor, of St. Mary's Hospital, and Henry Browne, of the Middlesex Hospital. Two candidates were referred for three months, and one for six months. One hundred and seventy-seven candidates presented themselves for the examination just completed, as compared with 196 at the corresponding period of last year; of this number 49 were referred for three months and six for six months, making a total of 55 referred candidates.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 8th, 1884:—

Clarke, James Fernandez Howard, 23, Gerrard Street, Soho, W.
Crisp, James Ellis, Lacock, Wilts.
Kiddle, Thomas, Ellore, Godavery District, Madras.

Royal Colleges of Physicians and Surgeons, Edinburgh.—*Double Qualification.* The following gentlemen passed their first professional examination during the April Sittings of the Examiners:—

Robert Archer Nesbitt, Belfast; William Gregory Davies, Lindfield, Sussex; William Henry Clark, Aylesbury; Benjamin Allen Maturm, Lymington; William Arthur Powel, London; Richard Harrison, Yorkshire; Samuel Blackwell Fenn, Somersetshire; Nathaniel Ingram Edghill, Demerara; Edward James Sheppard, Walberton, Sussex; Richard Kelly, County Longford; Albert Edward Tunstall, Durham; Alexander O'Reilly Blackwood, Belfast; William John Morton, New South Wales; James Edmund Leach, Rochdale; David Denholm Black, Cockburnspath; James St. Johnston, Birmingham; Richard Arnold Johnston, Belper; Allan Mill, Bushmills; Joseph Sandback Scott, Manchester; Frederick Buckham, Hereford; Alfred William White, Hawsker; George Thomas Smith Hughes, Doncaster; John Wingfield, St. Petersburgh; Louis Emile de Boucherville, Mauritius; William Henry Carter, Tiverton; James McGaw, County Down; Edwin Priestley, County Down; William Beale Marston, London; Robert John Willis, County Armagh; Hervie Theophile Dardier, Lyons; John Connell, Cork; John Thomas Haworth, Yorkshire; James Whitelaw Alexander, Lanarkshire; Morgan John Morgan, Carnarvonshire; Edwin Evanson Jones, Flintshire; John Edgar Tisdall, Castletown, Berehaven; Anthony Daly Dunn, Canterbury; Alfred Henry Whittell, Plymouth; James Thornhill Woodhouse, Stockport; Henry Powell, Curraleigh; Robert John Beacone, County Tyrone; James Williamson Patrick, County Cavan; Clarence Beesley, Southsea; Thomas Godley, Kerry; Duncan Robert Macdonald, Edinburgh; Arthur Fowell Turner, Wiltshire; Patrick Austin Moriarty, County Kerry; David Davies, Abingdon; Robert Thomson Paton, Edinburgh; Vincent Peter Mart, Salford; Devereux Gwynne Hughes, Llandilo, South Wales; Michael Fitzgerald, Ballynaly; Frank Reginald Longden, Geelong, Australia.

The following gentlemen passed their final examination, and were admitted L.R.C.P. Edin., and L.R.C.S. Edin., in April and May:—

George Todd, Manchester; Charles Burland, Isle of Wight; Frank Laird, Aberdeen; Frederick William Salter, Yorkshire; Lewis Gordon Lawson, Morayshire; John Scott Haldane, Edinburgh; Ernest Evan Llewellyn, London; John Leslie Clarke Cox, Rock Ferry; Richard James Sadlier Wheeler, Clonakilty; Hugh St. David Griffiths, Cheltenham; Sydney Morse, Crewkerne; Henry Robert Heather Bigg, London; Cyril Somerset Earle, Manchester; Robert Balfour Graham, Berwickshire; Herbert William Gibbs Doyne, Bournemouth; James Joseph Wandlass Pearcey, Southwick, Durham; Michael Domville Hart, Jamaica; Alfred Edward Drury, Dublin; Harold Arthur Tuxford, Boston; John Joseph McNulty, County Roscommon; Alexander McKerlie, Glasgow; Alexander Ernest George Langschmidt, Cape of Good Hope; Edward Campbell Hearne, County Mayo; Hugh Griffith Hughes, Holyhead; Henry Goodwyn, Lucknow; Percy Sprague Oram, Ashton-under-Lyne; George Vincent Fourquemin, Glasgow; Richard Hugh Brew, County Clare; William Griffith Evans, South Wales; Philip Edmund Perot, Demerara; Walter Wignall, Skipton-in-Craven; Thomas James Randolph Clarkson, East Cowton; Griffith Gryffydh Jones, Anglesey; Francis William Robert Scott, County Down; John Francis Thomson; Linlithgowshire; Bouverie Francis Primrose McDonald, Edinburgh; John Nicholson Constable, County Mayo; John Kenaz Goodall, Nottingham; Colin Campbell McFarlane, Victoria; Crosbie Bagnall Harvey, County Wexford; David Gibson Inksetter, Copetown, Ontario; John Thomas Jones, Holywell, N. Wales; John Williams Jones, Carnarvon, N. Wales; Evan Jones, Llansawel, S. Wales; James Warnock Elliott, Carrickfergus; Arthur Edward Newbery Browne, London; George McClean, County Monaghan; Henry William Faulkner, Monmouthshire; William Gregory Davies, Lindfield, Sussex; William Disbrow Brydone-Jack, New Brunswick; Samuel James Camac, Dervock; Thomas Kean, Galway; John Winchester Speer, Belfast; William Parklynn, County Derry; Vincent Octavius Taylor, Mauritius; George William O'Flaherty, County Galway; David Gilbert Donaldson, Perthshire; Charles Alfred Mitchell, Yorkshire.

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their first professional examination during the recent Sittings of the Examiners:—

Henry Hugh Williams, Holyhead; Arthur Edward Nevins, Liverpool; Walter Smithies, Clitheroe; John George Uppleby, South Africa; Ernest Edmund Taylor, Manchester; Robert Sinclair Smith, Edinburgh.

The following gentlemen passed their final examination, and were admitted L.R.C.S. Eng. :—

Robert Henry Blaikie, Edinburgh; Skene Keith, Edinburgh; John Thomarson, Carlisle; William Kirman Pauli, Lincoln; Robert Smailes, Whitby; Kolapurvala Jamsetjee Framjee, Kolapur, India; Samuel Garland Sharpe, Norwich; Charles Gilroy King, Pollockshaws; James Charles Francis Whicher, Gosport.

The following gentlemen passed their first professional examination for the licence in Dental Surgery :—

Leonard Latham Wilde, Winchester; and James Leslie Fraser, Inverness.

The following gentlemen passed their final examination, and were admitted L.D.S. Edin. :—

James Graham Munro, New York; and Alfred Henry Thomas, Chester.

King and Queen's College of Physicians in Ireland.—The following Licentiates in Medicine of the College, having complied with the By-laws relating to Membership, pursuant to the provisions of the Supplemental Charter of December 12th, 1878, have been duly enrolled Members of the College :—

James B. Barry, Licentiate of Medicine, 1870, Kilbeggan, county Westmeath; Maurice John O'Connor, Licentiate of Medicine, 1877, Sydney, New South Wales.

At the monthly examinations for the licences to practise Medicine and Midwifery, held on Monday, Tuesday, Wednesday, and Thursday, May 5th, 6th, 7th, and 8th, the following candidates passed :—

For the licence to practise Medicine—

Ernest Wickham Barnes, Liverpool; Henry Talbot Baylor, Fermoy; William Clifford, Thomastown, Kilmallock; Myer Akiba Dutch, Crewe; Francis Carleton Evans, Ballynahinch, county Down; James William Grene, Dalkey, county Dublin; Thomas Archibald Guinness, Kilburn, London, N.W.; Mary McGeorge, Newry, county Down; Matthew Macnamara, Limerick; Edward James Minchin, Dublin; Thomas Pierse, Wexford.

For the licence to practise Midwifery—

Robert Alexander Barber, M.D., R.U.I., Poyntzpass, county Armagh; Henry Talbot Baylor; Myer Akiba Dutch; Francis Carleton Evans; James William Grene; Thomas Archibald Guinness; Mary McGeorge; Matthew Macnamara; Charles Henry Maher, Sydney, New South Wales; Patrick O'Gorman, M.D., R.U.I., Bilston, Staffordshire.

Royal College of Surgeons in Ireland. — The College held a meeting on the 6th inst., pursuant to charter, to elect examiners for the ensuing year, when the following gentlemen were elected, viz. :—Examiners to examine candidates for Letters, Testimonial and Fellowship—Messrs. Edward A. Stoker, Edward S. O'Grady, Henry Gray Croly, William Thompson, Robert S. Swan, Wm. Fraser, Benjamin G. M'Dowel, and Phineas S. Abraham. Examiner in Ophthalmology—Arthur H. Benson, Esq. Examiners to examine candidates for the Diploma in Midwifery—Messrs. Henry Croly, John J. Cranny, and Edward J. Quinan. Examiners to examine candidates in General Education—Messrs. Henry J. Tweedy, Frank J. Davys, and Robert Morton.

The Library of the Royal College of Surgeons will be closed to-day (Friday, May 16th), for the purposes of the examinations.

University of London.—The annual meeting of convocation was held on Tuesday, but there were no matters of specially medical interest under discussion.

Outbreak of Typhus in Asia Minor.—An epidemic of typhus has broken out at a village near Smyrna.

Metropolitan Free Hospital.—The annual festival dinner was held, under the presidency of the Lord Mayor, on Tuesday, and resulted in an addition to the funds of the charity of nearly 4,000*l.*

Scarlatina at Waterford.—A serious outbreak of scarlatina is reported at Waterford, and the Fever Hospital is said to be crowded to excess.

Charitable Bequests.—Mr. Oxley English, who died on March 7th last, has bequeathed 1,000*l.* to Charing Cross Hospital, 500*l.* each to the Middlesex Hospital and the West Norfolk and Lynn Hospital, and 200*l.* to the City of London Truss Society.

Royal Society of Edinburgh.—At the last meeting of this Society, Professor Turner communicated a paper by Mr. Wynter Blyth, on the results of experiments made by him on the chief disinfectants of commerce, with a view of ascertaining their power of destroying the spores of anthrax bacillus.

The French Association for the Advancement of Science.—This body will hold its Thirteenth Annual Congress in the city of Blois, under the presidency of M. Bouquet de la Grye, Member of the Académie des Sciences, from the 4th to the 11th of September. At the last meeting of the Administrative Council of the Association, sums of money varying in amounts from 400 to 2,000 francs, and together exceeding 10,000 francs, were voted for the purpose of aiding in various scientific investigations.

Sanitary Institute of Great Britain.—At the annual general meeting held at the Parkes Museum of Hygiene on Wednesday, May 7th, Rt. Hon. Earl Fortescue in the chair, a report was presented by the Council on the progress of the Institute, and on the work achieved at the very successful Congress and Exhibition held at Glasgow in the autumn of 1883. The Chairman of Council, Dr. A. Carpenter, gave an address, and the officers for the ensuing year were elected, the president being His Grace the Duke of Northumberland, and the trustees Sir John Lubbock, Bart., D.C.L., F.R.S., Thomas Salt, Esq., M.P., and Dr. B. W. Richardson, F.R.S.

Army Medical Department.—Surgeon R. H. Gardner, of the Army Medical Department, has been appointed to take medical charge of the Headquarters Staff and Departments of the Army of Occupation at Cairo, *vice* Surgeon-Major Connolly. Deputy Surgeon-General S. C. Townsend, C.B., of the Bengal Army, and Deputy Surgeon-General W. B. Beatson, M.D., of the Bengal Army, to be Surgeons-General. Brigade-Surgeon J. R. Jackson, M.D., of the Bengal Army, to be Deputy Surgeon-General; Surgeon-Major W. P. Kelly, of the Madras Army, to be Brigade-Surgeon.

The Late Dr. Angus Smith.—Dr. Angus Smith, F.R.S., whose death at the age of 67 is recorded, was well-known for his investigations, in conjunction with Sir Lyon Playfair, on the sanitary conditions of the Lancashire towns, and also for his inquiry into the action of carbonic acid on the circulation of the blood, by experiments made in an air-tight chamber. In conjunction with Mr. M'Dougall, he examined the action of disinfectants, and especially recommended carbolic or phenic acid, pure or in tar-oil. His special inquiries into the quality of the air of towns when polluted by gases from manufactures led to his appointment by the Board of Trade, under the Alkali Act of 1863, as Inspector-General of Alkali Works for the United Kingdom.

Port of London Sanitary Committee.—By a recent warrant of the Treasury, the limits of the Port of London have been greatly extended. Commencing above at Teddington Lock, they extend down both sides of the River Thames to an imaginary line drawn from Navingore Creek on the north side, to the land's end at Warden Point, in the Isle of Sheppey, on the south side, including both sides of the Medway; as far as a line drawn from Colemouth Creek to Stangate Creek, from there to Swale Church, and from thence to Elmly Chapel, in the Isle of Sheppey, with all streams, docks, basins, creeks, islands, &c. The result of this warrant is to place under the jurisdiction of the Port Sanitary Committee of the Corporation of London an additional district of from 20 to 30 miles in length, and including the important ports of Sheerness, Queenborough, and Port Victoria.

Medical Education in Canada.—A writer in the *New York Medical Record* (March 8th) speaks in the highest terms of the superior kind of medical education that is pursued in Canada. He states that for some time past it has shown a distinct tendency to a practical character, the powers of observation being strongly brought into play. "From a somewhat extended acquaintance with the state of medical education in the United States and Great Britain, we cannot but think that Canada compares very favourably with both. It must be admitted that such old and large centres as Edinburgh, London, New York, and Philadelphia have advantages peculiarly their own. Yet when we look at the advantages and disadvantages to medical education in Canada, at the careful manner in

which both theoretical and practical teaching is given, and at the high standard fixed by the different curricula, it must be admitted that these schools are turning out a very efficient class of practitioners."

Medical Students in Italy. — In the "Statistical Report on Public Instruction during 1880–81," recently published, it is stated that the twenty-one Royal Universities, the four Free Universities, the three University *corsi* attached to the Lyceums, and the eight Special Superior Schools, together mustered, in 1880–81, 13,387 students, of which number 5,338 (40 per cent.) were medical students. There were 661 diplomas accorded during the year. The proportion of examined students who passed was 79·9 in the Royal Universities and 96·5 in the Free Universities. There were also attached to the Universities, Schools of Pharmacy, with 889 students; of Obstetrics, with 370; and of Veterinary Medicine and Phlebotomy, &c., with 99 students. Of the number of obstetrical and veterinary students attending schools unattached to the Universities no return is given.—*Annali Universali di Medicina*, March.

Sanitary Assurance Association.—At a meeting of the Council of this Association, at 5, Argyll Place, Regent-street, W., on Monday, May 12th, Sir Joseph Fayrer, F.R.S., in the chair, a discussion took place on the International Health Exhibition, in connection with a letter from Mr. H. Rutherfurd of The Temple, and on the motion of the Chairman, seconded by Lieut.-General Burne, C.B., it was resolved, "that the Medical Officer, Dr. James Stevenson, and the Sanitary Surveyor, Mr. Mark H. Judge, A.R.I.B.A., be instructed to visit the various departments of the Health Exhibition, connected with the drainage and water supply of dwelling-houses, for the purpose of reporting on the same to the Council and Members of the Association." The following resolution was also passed, on the motion of Mr. Barrington Kennett, seconded by Mr. Mark H. Judge, "that certificates be given to builders and plumbers who, having executed sanitary works under the direction and supervision of the Association, have completed the same to the satisfaction of the Medical Officer and the Sanitary Surveyor." At the same meeting it was decided to inspect and certify the sanitary condition of hotels of moderate size in any part of England on the same terms as private houses.

Glasgow District Asylum, Bothwell.—Dr. Sibbald, one of Her Majesty's Commissioners in Lunacy, in his report on the Bothwell Asylum, observes that most of the patients discharged had been found permanently fit for liberation. Though the number discharged continued to be exceptionally high, it might be inferred from the small proportion readmitted that due care was taken in selecting these patients. It resulted from the care that was taken not to detain patients after asylum treatment had ceased to be necessary, that the average length of residence for a patient in this asylum was between twelve and thirteen months, instead of being, as is the case in many asylums, more than three years, and in some asylums more than four years. It was evident that if such prolonged detention were the rule in this asylum, with its admission rate of about 160 per annum, an asylum not for 180 inmates, but one for 480 or 640 would be required, involving a great additional burden on the assessment of the district, and the unnecessary detention of from 300 to 460 persons.

The Prizes of the Belgian Academy of Medicine. —The following subjects have been announced for competition:—(1) Examine the influence of the nervous system on the urinary secretion, basing the observations especially on personal researches, 800 francs; essays to be sent to the secretary of the Academy on or before February 15th, 1885. (2) Determine by new experiments and applications, the degree of utility of spectral analysis in investigations in legal medicine, and medical police, 1,500 francs, 1st April, 1886. (3) Determine experimentally the influence which desiccation, employed as a means of conservation, exerts on medicinal simples of the vegetable kingdom, 600 francs, 1st July, 1885. (4) The physiological influence of abstractions of blood, whether local or general, and their indications and contra-indications in the treatment of disease, 1,500 francs, 31st December, 1885.

Medical Sickness, Annuity and Life Assurance Society.—It was reported at the last meeting of the Medical Sickness, Annuity, and Life Assurance Society, that the fund had already a position at which the numbers of members entered ensured the solidity of the society; and that there was an adequate margin, according to actuarial allowance, for the working expenses, which had hitherto been kept down to an unusually low point, and this would continue to be so. Arrangements were at the same time made for bringing the objects of the Society under the notice of the President and Secretaries of branches, with a request that they would submit them to the notice of members at forthcoming branch meetings; and communications were received from Mr. Brierley (Manchester), and Mr. Ravenhill (Birmingham), announcing the intention of taking early steps, as requested, to form local committees in those two great towns from existing members and others. It was resolved also that all members joining before the end of May, should rank as foundation members, and be entitled to the accruing advantage in respect to the date at which they would be free to receive the benefits of assurance. The whole of the preliminary expenses, up to date, were provided for, and written off, leaving the management fund untouched.

Dr. Vincent Richards' Experiments with Cholera Alvine Evacuations.—Dr. Richards having failed in obtaining any positive results from his experiments upon dogs with cholera evacuations, fortunately bethought himself that the pig would probably prove a more suitable animal for this purpose; and in the *Indian Medical Gazette* for April he summarises the results. These are remarkable and important, inasmuch as they show that the cholera evacuations contain what proves for this animal to be, under some circumstances, a deadly poison, analogous in its operation to the venom of snakes. The evacuations seem to lose their toxic power by decomposition, but whether the poison is given off or destroyed is, at present, uncertain, although the probabilities are much in favour of the latter supposition. At the present stage of the enquiry, Dr. Richards lays down the following propositions:—(1) That choleraic evacuations, at certain stages of the disease, contain a most virulent poison. (2) If this poison finds its way into the stomach, it is absorbed, and proves rapidly fatal. (3) The principal action of the poison is to enfeeble and destroy the function of respiration. (4) The poison is not an organism, but of the nature of a chemical compound of a comparatively unstable nature. (5) It will probably be found to be easy to destroy the power of the poison existing in the evacuations, in other words, to disinfect them. (6) Although the poison decomposes, it might by desiccation retain its powers for some considerable time. Hence, clothes, &c., stained with choleraic discharges, might be a source of danger. A later report states that Dr. Richards is inclined to regard the poison as a ptomaine or cadaveric alkaloid.

The Microbe of Yellow Fever again. — Not long since M. Rochard introduced to the notice of the Académie de Médecine the claims of M. de Lacerda as the discoverer of the microbe of yellow fever, and it now falls to his lot to bring forward those of a Brazilian physician, Dr. Domingo Freire, who has laid hold of another microbe, which he terms (*Union Médicale*, May 8) Cryptococcus xanthogenius. He has his preventive inoculations, too, and has operated upon some 400 persons, who have not died. It is true, indeed, that they have not as yet been exposed to the danger of an epidemic attack of the disease, so that the experiment can scarcely be regarded as complete. Dr. Rochard, in his report, expresses himself with judicious scepticism, and, while admitting that the discoverer, if all his pretensions are realised, will well deserve his statue, advises that the opening of a list of subscriptions be delayed until a few more convincing facts are adduced. The whole of the sitting of the Academy was occupied with the consideration of the microbe question in one form or another. The question, indeed, is fast threatening to become a pseudo-scientific nuisance, leading to the most hasty conclusions and impeding important researches.

NAPLES INTERNATIONAL HOSPITAL.—This hospital, the new wings of which, built under the superintendence of Mr. Samuel Young, will shortly be opened, has issued a very satisfactory report, so far as regards the increased amount of relief afforded, but less satisfactory in respect to finances. The number of patients admitted during 1883 was larger by 16 per cent. than in 1882. The patients newly admitted during 1883 were 182, of which the larger contingent was formed by Swiss, English, Germans, and Italians. Of 97 patients who were taken ill while passing through Naples, and admitted into the hospital, 31 were English sailors; most of whom paid at a reduced rate, and one was nursed and cured gratis. In consequence of the change of house, &c., a deficit of 31,700 francs has now to be provided for, and the committee trust—considering the increase of patients and gratuitous consultations (given to 316 persons, of whom 42 were English mariners), which have more than trebled since 1878, when the hospital was founded—that many societies and private persons who have profited by the institution may become liberal subscribers in future, and help the hospital through the critical financial period which it has now to overcome.

THE FRENCH HOSPITALS AND HOSPICES. — These two kinds of establishments amount in number to 1,580. In the provinces a great many beds are empty, while in Paris their number is insufficient, which, as regards the hospitals, it would not be, or only to a slight extent, if chronic cases were excluded. The 8,284 beds in the hospices of Paris are not sufficient with respect to their special destination, the number of registered aged persons who await their turn being more than 2,000. To each of these the Municipal Council distributes one franc per diem, by means of the *bureaux de bienfaisance*, but with even this aid the charge remains too heavy for the families of these poor persons. It has been suggested that aged persons should be sent to occupy the beds in the provinces, but the administration fears that such an exile so far from their families would be very distressing to them, and would deprive them of many little comforts which they now receive. Moreover, the payments which would have to be made would often be much higher than is generally supposed, as for example at the Asylum of St. Reine, where a charge of 3½ francs per diem is demanded for the sick and convalescent, while the charge at Paris is only 2 francs 30 cents. The Assistance Publique has therefore resolved to erect some new hospices in the environs of Paris, and with this intention has just acquired the Chateau Boissy, St. Léger, near Vincennes.—*Gazette Hebdomadaire*, May 9th.

APPOINTMENTS.

BINDLEY, V. N., M.R.C.S., L.S.A.—Assistant Surgeon to Her Majesty's Convict Prison, Dartmoor.

BREWSTER, W., M.R.C.S., L.S.A.—Resident Medical Officer to the York Dispensary, *vice* J. O. Horden, M.B., resigned.

BUCK, L. A., M.R.C.S.—Ophthalmic Clinical Assistant to King's College Hospital.

CASSAL, CHARLES E., F.I.C., F.C.S.—Public Analyst for High Wycombe.

CHEVES, J. T., M.R.C.S.—House Surgeon to King's College Hospital.

CHILDE, C. P., M.R.C.S.—House Surgeon to King's College Hospital.

ELLIS, HYACINTH D'ARCY, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Second Kingswinford District, Stourbridge Union.

HASELL, E. S., L.S.A.—Assistant House Accoucheur to King's College Hospital.

HODGSON, G. G., M.R.C.S.—Assistant House Physician to King's College Hospital.

JAMIESON, W. A., M.D., C.M., F.R.C.P.—Extra Physician for Diseases of the Skin, Royal Infirmary, Edinburgh.

LILBURNE, J. T., B.A., M.R.C.S.—Physician Accoucheur's Assistant to King's College Hospital.

MCGACHEN, F. W., L.F.P. & S. Glas., L.S.A.—Medical Officer to the Fifth District, Newport Pagnell Union.

MORRISON, J. T. J., B.A., M.B.—Resident Surgical Officer to the General Hospital, Birmingham.

NISBET, J. T., M.B., C.M.—Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

SHORT, T. S., M.R.C.S.—Physician's Assistant to King's College Hospital.

SPICER, FREDK., M.B., M.R.C.S.—Resident Medical Officer to the Royal Free Hospital, Gray's Inn Road, *vice* F. Norvill, M.B., M.R.C.S., resigned.

TATHAM, C. J. W., M.R.C.S., L.S.A.—Assistant Medical Officer to the Warneford Asylum, Oxford.

TURNER, N. H., M.R.C.S.—Assistant House Surgeon to King's College Hospital.

WILLIAMSON, RICHARD F., B.M. & M.C. Edin.—Medical Officer to the Langwathby District, Penrith Union.

WRIGHT, C. J., M.R.C.S.—Assistant Surgeon to the Hospital for Women and Children, Leeds.

VACANCIES.

BIRMINGHAM GENERAL HOSPITAL.—Resident Assistant Surgical Officer. (*For particulars see Advertisement.*)

DENBIGHSHIRE INFIRMARY, DENBIGH.—House Surgeon. Salary to commence at £85 per annum, with board, residence and washing. Candidates must be duly qualified. Conversant with the Welsh language. Applications to be sent to the Secretary, on or before June 5th.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free, &c. Candidates names must appear upon the Medical Register as being possessed of a medical and surgical qualification, and they must produce evidence of good moral character. Private practice strictly prohibited. Applications, with testimonials, to be sent to the Secretary, on or before June 11th. The election to take place on June 18th.

GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, N.—Ophthalmic Surgeon. (*For particulars see Advertisement.*)

METROPOLITAN ASYLUMS BOARD.—Medical Superintendent. (*For particulars see Advertisement.*)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—Pathologist, &c. (*For particulars see Advertisement.*)

ST. MARYLEBONE GENERAL DISPENSARY, 77, WELBECK STREET, CAVENDISH SQUARE.—Resident Medical Officer. Salary, £105 per annum, with furnished apartments, attendance, coals, and gas. Candidates must be registered, and hold a Medical and Surgical qualification. Written applications and testimonials, to be forwarded not later than May 19th, and candidates must attend at the Dispensary on May 21st, at 5 o'clock.

SUNDERLAND INFIRMARY.—Senior House Surgeon. Salary, £100 per annum, with board and residence. Candidates must possess double qualifications (registered). Applications, with testimonials, to be sent to the Chairman of the Medical Board, on or before June 2nd. The election will take place on June 12th.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, W.C.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

TOXTETH PARK TOWNSHIP.—Medical Officer for the Second District, in succession to Mr. Thomas Fox Morrish, resigned. Salary, £125 per annum.

DEATHS.

BAINBRIGGE, W. H., F.R.C.S., at Droitwich, on May 6th, aged 78.

CLARKE, W. F., M.D., F.R.C.S., of Southborough, Tunbridge Wells, at Bonchurch, on May 8th, aged 50.

COLLINS, W. J., M.D., at Albert Terrace, Regent's Park, on May 10th, in his 87th year.

GALE, H. S., M.B., at Manchester, on May 4th, aged 47.

MANSON, DAVID, M.A., C.M., M.D., at Eaglestone, Strathpepper Spa, N.B., on May 9th, aged 45.

MAY, GEORGE, F.R.C.S., at Sidmouth House, Reading, on May 8th, aged 85.

PINK, H. N., M.R.C.S., at Crooms Hill, Greenwich, on May 5th, aged 67.

TWINING, EDWARD, M.R.C.S., at The Chestnuts, Walthamstow, on May 12th, aged 68.

WURTZ, M., Professor of Chemistry, and formerly Dean of the Faculty of Medicine of Paris, on May 12th, in his 87th year.

NOTES, QUERIES, AND REPLIES.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Would you allow me to apologize to those gentlemen whose letters were accidentally returned by the Porter, and to ask them if they would kindly communicate with me again.

I am, Sir, yours, &c.,

3, *New Inn, London. W.C.* JAMES ROCHEID FORREST,
May 13th, 1884. Hon. Secretary.

COMMUNICATIONS RECEIVED—

MR. A. E. EKINS, F.C.S., St. Albans; MR. L. HOFF, London; THE DEAN OF THE MEDICAL DEPARTMENT, KING'S COLLEGE, London; THE REGISTRAR-GENERAL, Edinburgh; Dr. DALY, London; THE SECRETARY OF THE CLINICAL SOCIETY, London; THE SECRETARY OF THE HOSPITALS ASSOCIATION, London; THE SECRETARY OF THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS, London; Messrs. ALFRED REED & CORNEY GRAIN, London; THE REGISTRAR-GENERAL FOR QUEENSLAND, Brisbane; THE SECRETARY OF THE SANITARY ASSURANCE ASSOCIATION, London; Dr. HENRY BULLOCK, London; THE MEDICAL OFFICER OF HEALTH, PORT OF LONDON; Dr. WILLOUGHBY, London; Dr. C. MERCIER, Dartford; Dr. CLIFFORD BEALE, London; Dr. DONKIN, London; Dr. J. W. MOORE, Dublin; THE SECRETARY OF THE ROYAL INSTITUTION, London; Mr. I. W. VICKERS, London; Dr. ALTHAUS, London; THE SECRETARY OF THE PATHOLOGICAL SOCIETY OF LONDON; Messrs. WOOLLAMS & CO., London; THE SECRETARY OF ST. MARY'S HOSPITAL, London; Dr. MACCALL, London; THE PRESIDENT OF THE PHARMACEUTICAL SOCIETY, London; THE REGIUS PROFESSOR OF MEDICINE, UNIVERSITY OF CAMBRIDGE, Cambridge; Dr. BURNEY YEO, London; Mr. MAKUNA, Pontypridd; Mr. LAWSON TAIT, Birmingham; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Mr. E. WOOTON, London; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; THE HON. SECRETARY OF THE WEST LONDON MEDICAL SOCIETY, London; THE SECRETARY OF THE MEDICAL LIFE ASSURANCE SOCIETY, London; Messrs. J. HALL & CO., Stourbridge; Messrs. T. BRADFORD & CO., London; Dr. ISAMBARD OWEN, London; Mr. BANKS, Liverpool; Mr. WYNTER BLYTH, London.

BOOKS RECEIVED—

Die Entstehung der Menschlichen Rachendiphtherie, von Dr. Med. Max Taube—Annual Report of the Royal Edinburgh Asylum for The Insane for the year 1883—On the Poison contained in Choleraic Alvine Discharges, by Vincent Richards, F.R.C.S. Eng.—Addresses, &c., at the one hundredth Anniversary of the Foundation of the Medical School of Harvard University—Circolazione del Sangue, del Dott. Antonio Curci—Quarterly Return of the Births, Deaths, and Marriages register in Scotland, for the quarter ending March 31st, 1884—Report on the Sanitary Condition of the Whitechapel District for the quarter ended March 29th, 1884—The Student's Guide to Systematic Botany, by Robert Bentley, F.L.S., M.R.C.S.—Seize Années de Pratique Médicale a Contrexeville, par le Dr. Debout D'Estrées—Regional Surgery, Part ii., by F. A. Southam, M.A., M.B., F.R.C.S.—Histological Notes, by H. Horscraft Waters, M.A. Transactions of the Obstetrical Society of London. APPOINTMENTS FOR THE WEEK.

Friday, May 16 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m.—Prof. Odling, "The Dissolved Oxygen of Water."

Saturday, May 17.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL INSTITUTION, 3 p.m.—Professor Bonney, "Microscopical Geology."

Monday, May 19.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK, 5 p.m.—Dr. Julius Althaus, "The Causes of Locomotor Ataxy."

Tuesday, May 20.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. Warren Tay and Dr. Stephen Mackenzie, "Bromide of Potassium Eruption," with microscopical sections; Dr. Charlewood Turner, "Cerebral Aneurysms from two cases of Cerebral Hæmorrhage;" Dr. Percy Kidd, "Some unusual cases of Pulmonary Aneurysms;" Dr. Sharkey, (1) "Multiple Stricture of the Small Intestine;" (2) "A Case of Cystic Squamous Epithelioma" (card); (3) "Stricture of Stomach and Œsophagus, with Atrophy of Stomach" (card); Dr. Hadden, "Symmetrical Aneurysm of Middle Cerebral Arteries;" Mr. Chavasse, (1) "Tumour of petrous portion of Temporal Bone;" (2) Tumour of Skull" (card); Mr. Shattock, (1) "Congenital Malformation of Heart;" (2) "Unusual condition of Hydrocele Fluid" (card); Mr. Parker, "Congenital Talipes Calcaneo Valgus;" Dr. Barlow, "Drawings of a case of Congenital Xanthelasma;" Dr. Silcock, "Cancer of Prostate, with Secondary Ossific Deposit in Cranium and Femur;" Dr. Payne (for Dr. Handfield Jones), "Preparations of Pale and Red Clots in Cerebral Arteries;" Mr. Lockwood (for Surgeon Trevan, R.N.), "Chyluria, with Filariæ in the Blood and Urine" (living); Dr. Hobson, "Malignant Disease of Cæcum" (card); Mr. Morgan, (1) "Extensive Calcareous Deposit in Pleura" (card); (2) "Perforation of Occipito-Atloid Articulation of Cerebellum" (card); Dr. Hebb, (1) "A Sponge-like Liver" (card); (2) "The Muscular Nerves and Spinal Cord in Diphtheritic Paralysis" (card); (3) "Tubercle in the Wall of the Heart;" Mr. Lane, (1) "Tumour of the Bladder" (card), (2) "Partial Mollities" (card); Dr. Hale White, "Left Inferior Vena Cava" (card); Mr. J. Poland, "Suppurative Arthritis of Infants" (card).

ROYAL INSTITUTION, 3 p.m.—Prof. Gamgee, "Nerve and Muscle."

Wednesday, May 21.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

THE HOSPITAL ASSOCIATION, 8 p.m.—Third General Meeting, at 11, Chandos Street, Cavendish Square, W. Mr. Henry C. Burdett will read a Paper entitled "How can the Hospital Sunday and Saturday Funds be made more useful to the Hospitals?"

Thursday, May 22.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

ROYAL INSTITUTION, 3 p.m.—Prof. Dewar, "Flame," &c.

Friday, May 23.

CLINICAL SOCIETY OF LONDON.—Mr. Wm. Anderson, "A Case of Pyelo-lithotomy;" Dr. Finlay, "Sequel to a Case of Aortic Aneurysm;" Mr. Golding Bird, "Two Cases of Hernie en bissac;" Dr. F. Taylor, "A Case of Impaction of Bone in the Larynx;" Mr. B. Roth, "Uncommon Lateral Curvature of Spine, with extreme Osseous Deformity" (living specimen).

ROYAL INSTITUTION, 8 p.m.—Mr. D. Gill, "Distances of Fixed Stars," &c.

REMARKS ON A CASE OF TUBERCULAR TUMOUR AT THE BASE OF THE PONS.[1]

By Professor NOTHNAGEL.

GENTLEMEN,—I have already shown this man to you on account of pleurisy on the left side. I propose now to discuss other symptoms which he presents. Eight weeks ago he had a sensation of itching in the right arm and leg; a sensation combined with some weakness of the muscles. He can move the left arm better than the right, and the grip of the left hand is stronger than that of its fellow. We can hardly say that there is paralysis of the right extremities, but, at any rate, one cannot deny that there is paresis of those parts. You see, moreover, that the left facial nerve is paralysed; the eye-ball does not move when the patient looks to the left side; hence we diagnose also paralysis of the left abducens. When we ask the patient to press his teeth together the parts on the right side project much more than those on the left, the right masseter contracting more forcibly than that of the other side. The portio minor trigemini is therefore paralysed too. The tongue deviates a little to the left, and this proves that the right hypoglossal nerve is suffering from paresis. Besides these symptoms the patient has difficulty of articulation; he cannot pronounce the labial and lingual letters distinctly. We find, too, hyperalgesia of the whole right side of the body. The case therefore is one of crossed cerebral paralysis.

This kind of paralysis has been described by Gubler under the name of "paralysie alterne," but he described only the crossed paralysis of the extremities and the facial nerve. We now know, however, that not only the nerves of the extremities and the face may be affected by such a condition, but that other cerebral nerves are also subject to it. Thus there may be paralysis of the oculomotor nerve on the one side, with paralysis of the extremities on the opposite side; or the abducens and the portio minor trigemini of one side may be paralysed, while the extremities are paralysed on the other side. For the last ten years we have regarded it as possible, though only speculatively, that a monoplegia may be met with in cerebral disease, that only one extremity, for instance, may be paralysed, and we should refer such a paralysis to an affection of the cerebral cortex. But that is only a theory; in reality such a phenomenon has not yet been observed, and, if we do not find an alternate paralysis of the extremities, we can, *a priori*, say, with great probability of being correct, that the cause of the disease is to be sought in an affection of the spinal marrow. From the physiological point of view, the lesion which produces a crossed paralysis must be situated in a place from which a paralysis of the extremities on one

[1] Communicated to the Imperial Royal Society of Physicians of Vienna.

side of the body, and a paralysis of a cerebral nerve on the other side, may arise at the same time. In such a case the affection can only be situated in those parts of the central nervous system where such a paralysis can take its origin, though the lesion may be of no great extent. Such points are to be found either in the medulla oblongata, or in the pons, or at the commencement of the peduncles. We know, indeed, that the lesion which causes an alternate paralysis of the oculomotor nerve and the extremities, must be sought either in the commencement of the peduncles, or in the peduncular part of the pons, but the lesion is situated on the same side as that on which the oculomotor nerve is paralysed. Another sort of alternate paralysis is that affecting the facial nerve and the extremities. Here we draw the following conclusion : If the lesion is situated in the upper part of the pons, then it paralyses the facial nerve and the extremities on the same side ; but if its seat is in the lower part of the pons, then the paralysis is alternate, for the crossing of the facial nerve takes place in the pons, while the crossing of the nerves that supply the extremities occurs in the medulla oblongata. On a previous occasion I told you that in central paralysis of the facial nerve, its lower part only is affected, but in peripheral paralysis, all its branches are involved. We know, however, that the symptoms in alternate paralysis of the facial nerve are the same as those met with in the case of peripheral paralysis. Where there is complete paralysis, the electro-motor reactions are changed. We usually find, as Rosenthal has shown, a diminution of the Faradaic excitability, and sometimes degeneration reactions may be present, just as in peripheral paralysis. I would further draw your attention to the fact that the abducens is also paralysed. When this depends on an intra-cerebral lesion, you may presume that it occurs in the medulla oblongata itself, or at the base of the brain, the medulla oblongata or the pons being also involved. But there are also exceptions here, as in the case where there is loss of power in the lesser division of the fifth nerve, for this portion also takes origin in the pons or the medulla oblongata. We therefore draw the following general conclusion : If many cerebral nerves are affected, the disease arises from a lesion at the base of the brain, and not from an intra-cerebral lesion. In this case the following nerves are affected : The hypoglossal, the facial, and the lesser division of the fifth. Now, if the affection were situated in the medulla oblongata, or in the pons itself, it must be of some considerable extent, and, if this were the case, it would be very probable that the extremities would be affected in a higher degree than they are ; there would be not only paresis, but paralysis. The arm is not really paralysed, it is only slightly weak. The abducens and the fifth, however, are much more seriously affected. Therefore, as the affection of the cerebral nerves is of large extent, and as the affection of the extremities bears no proportion to that of the cerebral nerves, we conclude that the seat of the affection must be sought for at the base of the brain, in the posterior fossa. The lesion must be at the base of the pons, so that it presses upon the hypoglossal and the nerves of the extremities in the pons itself ; but upon the facial, the abducens, and the motor division of the fifth, when they are no longer intra-cerebral. Besides this, the pressure on the abducens and the lesser division of the fifth must be more marked than that on the facial nerve.

What kind of lesion have we in this case ? We must first take into consideration the fact that the above-mentioned symptoms have arisen under our observation in the hospital, and have gradually and slowly developed, so that it is certainly not a case of hæmorrhage. We must look out for an affection which developes itself gradually, and such affections are : tumours and chronic meningitis. There is no dilatation of the pupil, but the absence of this does not prove that the affection does not arise from a tumour, for it is probable that the tumour is small, otherwise death would have already occurred. If we exclude aneurysm of the basilar artery, to which Griesinger was the first to draw attention, our diagnosis is limited to that of tumour. Chronic meningitis may produce the same symptoms as tumour, but in this case we have no certain evidence of its presence. Excluding an injury, chronic meningitis is produced by the following causes : chronic alcoholism, syphilis, and tuberculosis. The patient says that he has not had syphilis, he has not been the subject of alcoholic abuse, and he presents no symptoms of tuberculosis. Nevertheless tuberculosis may possibly have developed as a result of pleurisy. Hence we diagnose tumour with a great possibility of being correct. What sort of tumour can it be ? He has not had syphilis, therefore it is probable that tubercle has developed in the locality mentioned above. There is no question of treatment here ; we shall give him from 30 to 45 grs. of iodide of potassium a day.

Verification of the Diagnosis.—At the *post-mortem* pleurisy on the left side was found. When the patient was alive, we did not perform paracentesis, as the cerebral symptoms had already attained a high degree, and we could not give a good prognosis. I diagnosed a tumour in the brain, and was disposed to consider it of tubercular nature on account of the pleurisy. We localised the seat of the tumour in the left part of the pons. The autopsy has verified the diagnosis. Diagnosis of the locality of a lesion is therefore possible with considerable probability of being accurate. You remember a case in which we diagnosed tubercle in the middle of the vermis, and it was actually found there in the *post-mortem* room. Since the experiments of Fritsch and Hitzig much attention has been devoted to the localisation of cerebral affections, especially of lesions situated on the surface of the brain. At present two parties are still opposed to each other as regards the possibility of localising lesions. One party, of which Munk is one of the chief, are of opinion that localisation is possible ; others are of an opposite opinion, among these Goltz, of Strasburg, is the chief representative. As to my opinion, I consider it possible to diagnose the seat of a cerebral affection in most cases with a high degree of probability. We can with certainty localise an affection in the posterior part of the left frontal convolution ; further, we can diagnose tumours in the right and left central convolutions. As to these divisions of the cerebral cortex, I am convinced, from the clinical stand-point, altogether apart from the physiological one, that lesions can be localised. We can even make diagnosis so precise as to determine whether the affection is to be sought in the middle or the lower part of the central convolutions ; nay, I think it possible that a localisation-diagnosis can be made in the paracentral lobule. Diagnosis as to the seat of lesions in the deeper parts of the brain is also possible. A lesion can be localised with certainty in the middle crura of the cerebellum, and the vermis ; and, under certain conditions, in the corpora quadrigemina, in the cerebral peduncles, in the posterior part of the internal capsule, in the pons, the medulla oblongata, and also round the aqueduct of Sylvius. Localisation is most difficult in the anterior parts of the brain. If you take into consideration the localities mentioned above, you will see that a great many nerves may be affected, and the combination of the symptoms renders it possible to make a diagnosis with certainty. You see that it was not difficult for us to diagnose the tumour in the pons. The disease developed itself gradually, therefore we diagnosed a

tumour. The possibility of a softening of the brain was given up, because the later course of the disease was against it. The course of the disease decided us to diagnose a tumour, though a very important symptom, namely, dilatation of the pupil was absent. The patient grew more and more stupid, every day he became weaker. If a large portion of the brain is affected, "atrophy of the brain may develop itself" as a consequence of this affection. In the case of our patient, we were driven to the conclusion that the lesion was of no great extent, and that it was in a place from which many nerves take their origin; we had to look for an affection in which it was possible for a secondary weakness of mind to take place without softening of the brain; and this, in fact, was possible in the case of tumour in the pons. The tumour, by pressing on the venæ Galeni, might cause effusion into the lateral ventricles, with consequent stupidity. This, indeed, was found to be the case, the ventricles containing a large quantity of serum. At the beginning of the affection the patient had also troubles of the sensory nerves, and this was an additional reason for diagnosing a lesion in the pons; for both in this affection and in the case of a lesion in the peduncles, the sensory nerves are more seriously involved than in affections which occur in the upper parts of the brain.

PATHOLOGICAL EXHIBITIONS.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S., Eng.
President of the Epidemiological Society of London.

I CONSIDER that the practice, long since adopted by certain of our Medical Societies, of bringing the subjects of remarkable diseases to their meetings, might be imitated and largely extended with great advantage to science and to the cause of suffering humanity. I think that there are very few experienced medical men who, when reviewing the course of their lives' observation, do not regret to find that they have entirely missed seeing many important things with which their neighbours are familiar. Thus, although I have carefully observed disease for fifty years, there are scores of pathological conditions with which I have not the very slightest practical acquaintance. I will take three diseases. I have never seen a cretin or a case of myxœdema, and I only once had a glimpse of a not unquestionable case of tetany. Near as I am to the termination of my career, it would give me valid satisfaction to have an opportunity of seeing and investigating five, four, nay three typical examples of each of these diseased states, and then to be present at lectures, fully illustrating these conditions, by Professor Flower, Dr. Ord, and Dr. Gowers. Now that the paying system is coming into vogue at more than one of our great hospitals, this object may, if a hundred of my professional brethren think as I do, be readily carried into effect. By an annual expenditure of 100*l.* or guineas, we could bring twenty patients, in batches of five, to one or more of the Metropolitan hospitals, keeping each person in the house for a week; doubtless, at the end of that time, the authorities would consent to retain some, as free patients, to a termination. Here our subscribers would have full opportunity of examining the cases, and I am certain that there would never be wanting a man who, having made each type of disease a special study, would demonstrate the cases before the patients returned home. I think that the medical journals would gladly publish these lectures, and that their printers would send extra copies to subscribers at a very small cost. We ought to advertise, naming the disease to be next exhibited and informing the profession throughout the United Kingdom that we would receive five typical cases for a week, paying the expenses of each, and giving a sovereign to every person on his return home. Thus the cost of each case would be 5*l.* For the hospital 1*l.*; for travelling expenses and gratuity 3*l.* (often less); for re-printing the transactions 1*l.* All the patients would, of course, be volunteers; the move would have an obviously direct tendency to benefit them, and the trip to London might, with a little benevolent aid, be rendered extremely pleasant to these unfortunates. With larger means, the Society might readily bring to England cases of foreign disease which, under present circumstances, no home practitioner can hope to see—Pellagra, Yaws, the Scrotal Elephantiasis, Mycetoma, Delhi Boil, Leprosy and Ainhum of the East, and the Coco-Bay and Chigoe of the West Indies, and many others. The subscribers should elect annually, by voting papers, a small working body of four, President, Vice-President, Treasurer, and Hon. Secretary, empowered to use full discretion in arranging for the exhibitions, either in four consecutive weeks or once in every three months. These should meet at each others' houses and incur no expense to the Society except for postage.

LUNATICS OF FOREIGN NATIONALITY.

By CHARLES MERCIER, M.B.[1]

GENTLEMEN,—I desire to draw your attention to a class of persons probably the most unfortunate and the most unhappy in her Majesty's dominions; and not only to them, but to another and probably more numerous class of our fellow-countrymen, who are immured in the asylums of foreign nations, and are separated by impassable barriers from their country, their home, and their friends. The facts are doubtless sufficiently familiar to all present, but this is one of those cases in which familiarity has, I will not say bred contempt, nor even indifference, but has allowed all vivid recognition of the facts to lapse out of consciousness. In the same way those who are always resident in a mill become at length unconscious of its uproar. It may not therefore be superfluous to dwell on the subject with a little insistance.

The lot of a lunatic sequestered in an asylum is at the very best a forlorn and pitiable one. It is pitiable even when it is alleviated by every amelioration that affection can prompt, that ingenuity can devise, or wealth can purchase. Even the lunatic who is blest with abundance of this world's goods, and with the more effectual solace to be found in "troops of friends," is in pitiable case, for he is deprived of the most precious of all human possessions—his personal liberty. The fate of the pauper lunatic is far harder, but few of us, I venture to think, familiar as we are with the facts, realise the full severity of what they have to bear. They live a life in common; solitude and privacy are to them unknown. Day and night, month by month, and year after year they are compelled to associate with companions whom they have no voice in choosing, and whose manners and habits are many of them distasteful and repulsive in the extreme. Of the chronic lunatic it may truly be said that he labours without reward, he lives without hope, and he dies unregretted.

Dark as this picture is, it by no means represents the worst. There is one class of lunatics the special

[1] Read before the Medico-Psychological Association, May 7th, 1884.

hardship of whose lot forms a conspicuous feature in every report of the Commissioners in Lunacy, and whose troubles form a perennial text for their homilies. These are the out-county patients; and we are all familiar with the forcible expressions with which the Commissioners refer to the justice of their complaints that all access of friends is denied to them. Confined in an asylum outside the limits of the county to which they belong, they are so far separated from their homes either by distance or by time, or, what is equivalent to both, by expense, that they are precluded from even an occasional visit of those who are near and dear to them. Still, however, they are among their fellow-countrymen. They are among those whose manners and customs and ways of living are akin to their own, who speak the same language, and to whom they can without difficulty make known their wants. It is far otherwise with the unfortunate people on whose behalf I now appeal to you. Separated from their native country, from home, from family and friends, there are not a few of these unhappy beings who are unable to speak a word of the language spoken around them, and who are as completely cut off from all human converse as if they were condemned to perpetual solitary confinement. In the midst of a crowd they live a life of unutterable loneliness. The people by whom they are surrounded, but from whom they are separated by a barrier impassable, although impalpable, are foreign to them in language, in habits, in mode of life, and in religion. Deprived of country, of home, of liberty, of reason, and of all companionship, their lot is one which, for the elements of unhappiness that it contains, can scarcely be paralleled among the human race. When we remember that this description applies not only to those citizens of foreign nationality who are immured in the comfortable asylums of our own land, but in a still more aggravated sense to those of our own countrymen who are sequestered in the bare and comfortless asylums of some continental countries; when we remember that the system of management and treatment of lunatics is not in all countries as humane and merciful as it is with us; when we bear in mind that the roving disposition of our race must ensure the existence of a greater number of Englishmen in foreign asylums, than of foreigners in the asylums of this country; the appeal to your sympathies and to your sense of justice will become, I hope, irresistible.

The charge of impracticability will, of course, be brought against the scheme that I advocate, but I submit that that is a very imperfect defence of the present state of things. The resolution that I have the honour to propose, formulates a principle. It does not attempt to enter into details of practical working, for that is, as I imagine, not within the scope of our functions. The difficulties in the way of making a working arrangement may be great, may, if you please, be insuperable; but what does man come into this world for, but to make difficult things easy, and impossible things possible? If we do not move in this matter, no one else will; but our function is to supply not the machinery, but the force to move the machinery. The evil will not be remedied until the facts are known, and unless we publish the facts, they will not be made known. We may not succeed, but we can at least do our best, and attain the relief of knowing that the responsibility for the evil does not rest upon those who have done their best to remedy it.

Gentlemen, I feel that I have put the case before you with not a tithe of the force that it deserves and demands, but I trust that the excellence of the cause will make amends for the imperfection of the advocacy, and will of itself suffice to command your sympathies, and enlist your suffrages.

I beg to move—(1) "That whereas the confinement of persons in lunatic asylums of nationality foreign to their own, places such persons in a position of peculiar and exceptional hardship, it is, in the opinion of this Association, extremely desirable that arrangements should be made between this and other nations for the transference of such persons to the country to which they belong." (2) "That a copy of the foregoing resolution be forwarded to the Secretary of State for Foreign Affairs."

AN EXAMINATION OF THE THEORY OF AËRIAL DISSEMINATION OF SMALL-POX INFECTION.

By MONTAGUE D. MAKUNA,
Late Medical Superintendent of Fulham Small-pox Hospital.

(Continued from page 661).

The Year 1877.

THERE were 2,544 deaths from small-pox in London, of which 39 occurred in Kensington, 18 in Chelsea, and 72 in Fulham (including 47 in Fulham Small-pox Hospital). Calculating at the rate of 15 per cent. 84 deaths among private cases, would give us the number 560 treated at home. The metropolitan small-pox hospitals admitted 6,750 cases from the whole of the metropolis, of which 263 were from Kensington, 86 from Fulham, and 195 from Chelsea, giving a total of 544 for the district. The Highgate Small-pox Hospital admitted 112 cases from Fulham, 26 from Kensington, and 13 from Chelsea. So that the total incidence of the disease in Kensington was 549, in Fulham 378, and in Chelsea 328, or 1,255 cases for the three districts between which the hospital is situated. Mr. Power takes 544 admitted from the three districts into the metropolitan hospitals as the incidence of the disease, and ignores the admissions to Highgate Small-pox Hospital and the private cases, which together form a much larger proportion than the number accounted for by him, especially in the case of Fulham. According to the Medical Officer of Health for Fulham, 328 cases were known to the sanitary authorities, of which 119 were in Hammersmith, and 209 in Fulham. He further states that 84 per cent. of the former and 45·9 per cent. of the latter were removed to the hospitals. He remarks, "This difference in the percentage of cases properly isolated is sufficient to account for the great difference in the number of cases occurring in the two parishes. . . . . The most energetic efforts were made to get cases removed to hospitals, but, unfortunately, a large proportion of patients remained to spread the disease, without proper accommodation or means of isolation. Some of the medical men in the district, and nearly all those in Hammersmith, did all in their power to assist us in the removal of cases. . . . . Unfortunately there was a very different course adopted by some, though I am very glad to say few. I found numerous cases treated with the worst possible accommodation." Mr. Power calculates his theory on 86 cases admitted from Fulham, and omits 112 admissions to Highgate Small-pox Hospital, and 132 private cases known to the Medical Officer of Health. I now turn to Kensington. According to Dr. Dudfield there were 399 reported cases, of which 114 were treated at home and 26 were removed to Highgate Small-pox Hospital, so that he omits 140 Kensington cases. The Report of the Medical Officer of Health for Chelsea gives us 266 cases, and they are estimated to be 328, of which Mr. Power takes up 195.

The onus of the introduction of the disease in the neighbourhood does not lie with the hospital, for it is proved that before the opening of the hospital on the 10th March, the other metropolitan hospitals received

47 cases from Kensington, 21 from Fulham, and 14 from Chelsea during the year. During the same period Highgate Small-pox Hospital admitted 10 from Kensington, 19 from Fulham, and 6 from Chelsea. The incidence of the disease for January, February, and March was, according to the known cases, as follows :—Fulham C. C. 1, ½ mile R. 1, ¾ mile R. 6, 1 mile R. —, O. S. A. 7. = 15 cases. Kensington C. C. —, ½ mile R. —, ¾ mile R. —, 1 mile R. —, O. S. A. 18. = 18 cases. Chelsea C. C. —, ½ mile R. —, ¾ mile R. 1, 1 mile R.—, O. S. A. 6. = 7 cases. To this must be added the incidence (on houses) given by Mr. Power in his tables, as the above cases are those not included in his. Unfortunately he gives the total for the three districts, which is not the best way of dealing with the subject. It is as follows :— C. C. 1, ½ mile R. 1, ¾ mile R. 6, 1 mile R. 5, O. S. A. 73 = 86. In the Monthly Report, No. 1, dated 7th February, Dr. Dudfield, of Kensington, reports that during the previous four weeks, 43 cases were known to him, of which 6 were convalescents whose illness was concealed from the sanitary authorities until too late. Nineteen cases were treated at home, of which 4 proved fatal. On the death of an unvaccinated child a sanitary inspector discovered 10 cases of small-pox in a house. A case was reported ill on the 28th December, 1876, and within five weeks 3 cases from the same family were removed to Hampstead Hospital. An unvaccinated baby was taken ill and treated in a room with nine inmates; her sister was taken ill and it was with difficulty the father was persuaded to send her to the hospital. Two cases were treated in a kitchen in Goldborne Terrace, O.S.A., and they were removed to a hospital after an application to the magistrate. A friend of theirs was lying ill in an adjoining house. Dr. Dudfield's Monthly Report, No. 2, dated 7th March, shows that during the previous four weeks there were 26 new cases and 4 deaths from small-pox. Two fatal cases were recorded in Goldborne Terrace, O. S. A., where 2 cases were reported during the previous month. A private case was treated in Southam Street, where another occurred. Two lads were treated at home who gave it to their father. A man, Lawson, was committed at the police court for the offence of sending infected clothing to a laundress. Several cases of small-pox had occurred in the defendant's house and a fatal case of a child was certified as that of "diarrhœa" early in January. The laundress discovered a sheet covered with scabs, and on pressing her enquiries she found that infected clothing had been sent to the wash weeks before. The date of the offence on the summons was 18th December, 1876. On the 19th, the daughter and niece of the laundress sorted the clothes, and on Monday the 1st January, both were taken ill. About this time the nephew of the laundress, a soldier on leave, went down to her house. He left for Birmingham on the 15th January, ill with symptoms of small-pox, and died on the 18th. His death certificate was signed by the regimental surgeon as "Epidemic Spinal Meningitis." A woman who washed his clothing became ill in turn. These facts prove that the disease was gaining ground in the locality before the opening of the hospital on the 10th March, 1877. I shall now give the incidence of the disease month after month.

March.—Fulham Hospital admitted 14 acute cases males above 7 years), 11 from Wandsworth and Clapham, 2 from Fulham and 1 from Chelsea; Highgate Hospital admitted 20 from Fulham, 2 from Kensington, and 1 from Chelsea. Dr. Dudfield's Monthly Report, No. 3, dated 4th April, records 24 cases since 7th March. There were 109 convalescents transferred to Fulham Hospital. The Medical Officer of Health for Chelsea records 12 cases. The cases under treatment during the succeeding weeks were 45, 67 and 101.

Fulham Cases.—(1) One from 24, Hildyard Street, C. C., to Hampstead Hospital, on the 2nd. (2) One from 9, Orchard Street, ¾ mile R., to Hampstead Hospital, on the 31st. (3 to 22) Other 20 Fulham cases admitted to Fulham and Hampstead Hospitals were O. S. A. They were 6 from three houses in Brewhouse Yard, Hammersmith, 2 from two houses in Angel Road, and 1 each from Broadway, Devonport Road, Chapel Street, Vernon Street, Bridge Street, Cambridge Terrace, King Street, Rose Gardens, Glenthorn Road, Florence Gardens, Birchwood Cottage, and Grafton Terrace. Excepting the last 2 cases, they are not included in Mr. Power's incidence of the disease. This enumeration of cases might be considered tedious by some, but it is of vital importance because it shows that Mr. Power's method of counting each house as a unit, regardless of all other considerations, drawing averages on palatial residences, in which servants took small-pox from outside, and poor men's houses, is unsound. Again, a plain statement of facts is in itself a satisfactory disproof of an hypothesis. It was at this time that two medical men were gaining notoriety as "small-pox curers," and were encouraging concealment of cases. Dr. Dudfield in his Report for March, gives the history of a fatal case which is very instructive. "The deceased, a single woman, aged 34, living at Notting Hill, occupied the front room on the first floor. On the 18th, a friend came down to see her but was not admitted to the room, as she thought she was suffering either from small-pox or erysipelas. From that day she was seen no more alive, nor anything so much as heard of her by the other inhabitants of the house. But the dog began to bark and howl on the 21st March, and continued to do so until the door of the room was broken open late at night on the 23rd March. A frightful spectacle was then presented. The wretched creature was found lying on her back on a bed naked, exposed and dead. The state of the room from filth of every sort, and the evidences of entire neglect and wretchedness exceed belief. An inquest was held, and the body was buried on 27th March. This gave rise to 3 more cases. The 2 Kensington cases admitted to Hampstead Hospital, were 1 each from Cornwall Road, Westbourne Park, O. S. A., and Porter Road, Notting Hill, O. S. A. The two Chelsea cases were 1 each from Westbourne Street, O. S. A., and Kensal Town, O. S. A.

April.—Fulham Hospital admitted 24 acute cases, of which 7 were from Fulham, 3 from Kensington, 10 from Chelsea, and 4 from Wandsworth. The Hampstead Hospital admitted 12 from Fulham and 2 from Kensington. Dr. Dudfield in his Monthly Report, No. 4, dated 2nd May, states that during the previous four weeks, there were 39 fresh cases, and 3 deaths in Kensington. Sixteen cases were treated at home, and he states that the increase was due to the concealment of cases and treatment at home by unqualified practitioners. Three cases occurred in the house in which the dead body of the woman was discovered as mentioned in the previous report. During the month there were 62 convalescents transferred from others to Fulham Hospital, and the weekly number of cases under treatment was 94, 101, 95 and 63.

Fulham Cases.—(1) One from 37, St. Oswald's Road, C. C., to Hampstead Hospital, on the 3rd. (2) One from 61, May Street, ¾ mile R., to Fulham Hospital, on the 5th. The street has many laundries, and several members of the hospital staff lived there. (3) A child from 6, Providence Place, ¾ mile R., to Fulham Hospital, on the 10th. Several cases were treated at home, and the child was ill ten days before removal. (4) One from 6, Hilmer Street, ¾ mile R., to Fulham Hospital, on the 11th. (5) One from 3, Wheatsheaf Alley, ¾ mile R., to Fulham Hospital, on the 26th. Some of the hospital staff lived in the street. (6 and 7) Two from 27, Stud-

*

land Street, O. S. A., 1 to Hampstead Hospital, on the 6th, and the other to Fulham Hospital, on the 7th. Cases of small-pox in the house since January. (8 and 9) Two from 3, Blyth Terrace, O. S. A., 1 to Fulham Hospital, on the 7th, and the other to Hampstead Hospital, on the 19th. Several cases of small-pox in the street. (10 and 11) Two from 3, Chancellor Street, O. S. A., 1 to Fulham Hospital, on the 9th, and the other to Hampstead Hospital, on the 24th. Small-pox in the street. (12 to 14) Three from 10, Brewhouse Yard, O. S. A., 2 on the 5th and 1 on the 24th, to Hampstead Hospital. Infected house. Several cases in street, and six removed to Hampstead Hospital previous month. (15 and 16) Two from 30, Alma Cottages, O. S. A., 1 on the 7th, and the other on the 25th, to Hampstead Hospital. (17 to 19) One each from 29, Hanover Cottages, 2, Ainsvale, and 10, Witham Street, to Hampstead Hospital, on the 13th, 28th and 30th.

Kensington Cases.—(1) One from 4, Fawcett Mews, ½ mile R., on the 25th, to Fulham Hospital. (2 to 5) One each from 325, Portobello Road, and 26, Goldborne Gardens, O. S. A., to Fulham Hospital, on the 26th; and 21, Athelstone Mews, and 10, Phillimore Gardens, O. S. A., to Hampstead Hospital, on the 2nd and 19th respectively.

Chelsea Cases.—(1 to 5) Five occurred in Kensal Town, O. S. A., between two and three miles from the hospital. (6) One from 22, Seaton Street, ¾ mile R., to Hampstead Hospital, on the 7th. (7 and 8) A boy from 42, Blantyre Street, ¾ mile R., to Hampstead Hospital, on the 9th, his brother on the 21st. (9 and 10) One from Chelsea Hospital, O. S. A., to Hampstead Hospital, on the 12th, and the other from 27, Paradise Walk, on the 16th.

May.—Fulham Hospital was now ready for the reception of cases of both sexes, and at all ages; the total admissions were 64 acute cases, and 98 convalescents. The acute cases were, 7 from Fulham; 11 from Kensington; 34 from Chelsea; 11 from Wandsworth, and 1 from Westminster. Highgate Hospital admitted 21 from Fulham; 2 from Chelsea, and 2 from Kensington. Dr. Dudfield's Monthly Report, No. 5, dated 30th May, gives 43 new cases, and 2 deaths during the four previous weeks. Most of the Kensington cases occurred in Kensal New Town and the adjoining parts, between two and three miles away from the hospital. The Medical Officer of Health for Chelsea reported 54 cases. Several applications were made to the magistrate at Hammersmith for the removal of cases from Fulham, where the landlords wanted to eject the tenants suffering from small-pox, whose families of five and seven persons were living in one room, the children, moreover, playing together in the street. The weekly number of cases under treatment at Fulham Hospital was 48, 66, 101, and 142.

Fulham Cases.—(1) One from a street in Walham Green, C. C., to Fulham Hospital, on the 19th. It was the child of a man and his wife employed in the laundry of the hospital and who slept outside; their other children had already had small-pox and been treated at home. (2) One from Seagrove Road, C. C., the street in which Fulham Hospital is, to the Hampstead Hospital, on the 20th. (3) A child, from 2, Bective Road, ½ mile R., to Fulham Hospital, on the 20th. It was that of a man and his wife engaged in Fulham Hospital as nurses, and who had lodgings at the above address. Their other children suffered from small-pox, but were treated at home. (4) One from 3, Jervis Road, ½ mile R., to Fulham Hospital, on the 20th. (5) One from 2, Princess Terrace, ½ mile R., to Hampstead Hospital, on the 15th. (6 and 7) Two from 2, John's Place, ½ mile R., to Hampstead Hospital, one on the 16th and the other on the 18th. (8) One from 14, Crown Street, ¾ mile R., to Fulham Hospital, on the 19th. (9) One from 4, Pownal Road, ¾ mile R., to Fulham Hospital, on the 10th. (10) One from Russell's Cottages, ¾ mile R., to Hampstead Hospital, on the 19th. (11) One from 7, Rectory Place, 1 mile R., to Hampstead Hospital, on the 4th. (12 and 13) One each from 13 and 24, Rylstone Road, 1 mile R., to Hampstead Hospital, on the 12th and 28th. Several cases of small-pox in the street. (14) One from 10, William Street, 1 mile R., on the 16th, to Hampstead Hospital. (15) One from 16, Ancill Street, 1 mile R., on the 18th, to Hampstead Hospital. (16) One from 19, Bedford Place, 1 mile R., to Hampstead Hospital, on the 19th. (17 to 28) Twelve cases were from Outside Special Area. They were 2 from 4, Mitre Row, 1 from Hant Street, 2 from Hanover Cottages (infected houses), 1 from Wilson's Road, 1 from Norfolk Terrace, 1 from Angel Row, 1 from Elrice Terrace, 1 from Church Road, 1 from Suffolk Cottage, and 1 from Wharf Terrace.

From the above history it is evident that Fulham, within the Special Area, especially in the neighbourhood of the hospital, became infected through the free intercourse of the hospital staff residing outside. It was well known that male and female nurses, laundry people, porters, &c., received visits from their friends, waiting outside the hospital gates till they were free, and then promenaded the streets and visited the places of refreshment in the neighbourhood. Several complaints were made from public-houses, and some members of the staff were taken before magistrates charged with drunkenness and fighting.

Kensington Cases.—(1 to 13) The 13 Kensington cases were from O. S. A., 2 from Southam Street, 1 each from Lancaster Road, Bangor Street, Norfolk Terrace (imported case), Stafford Terrace, St. Luke's Mews, Hazlewood Crescent, Bevington Road, Alma Cottages (infected house), Pembroke Place, St. Anne's Road, and Silver Street.

Chelsea Cases.—(1) One from 22, Luna Street, ¾ mile R., to Fulham Hospital, on the 26th. (2) One from 20, Luna Street, ¾ mile R., to Hampstead Hospital, on 17th. (3 to 37) The remaining 34 cases occurred in O. S. A., and of these 14 were in Kensal New Town. The 20 cases in O. S. A. were — 3 from Bywater Street, 4 from Wellington Buildings, 2 each from Little Kepple Street, Pimlico Road, Lower George Street, and King's Road, and 1 each from College Street, Radnor Street, Paradise Walk, Arthur Street, and Standfield Street. Had the theory of aërial infection been borne out by facts, the Special Area in Chelsea and Kensington should have been equally infected with that of Fulham. Moreover, it has been ascertained that a large number of cases in the Special Area of Fulham were concealed or treated at home. It is monstrous to draw averages on houses in the Special Area of Fulham, Kensington, and Chelsea, when cases have occurred only in Fulham.

June.—Fulham Hospital admitted 75 acute cases, viz., 41 from Kensington, 5 from Fulham, 23 from Chelsea, 2 from Paddington, 3 from Westminster, and 1 from Wandsworth. Highgate Hospital admitted 11 from Fulham, 3 from Kensington, and 1 from Chelsea. Dr. Dudfield, in the Monthly Report, No. 6, dated 27th June, reports 50 new cases and 3 deaths. The Medical Officer of Health for Chelsea reported 30 cases. During the month 20 convalescents were transferred to Fulham Hospital; and the cases under treatment, week by week, were 144, 130, 107, 90, and 74.

Fulham Cases.—(1) One from Rickett Street, C. C., to Fulham Hospital, on 15th. He was a bricklayer, working on fever hospital premises. (2 and 3) Father and son, from 9, Wyatt's Terrace, 1 mile R., to Fulham Hospital, on 1st and 15th. (4) A domestic, from Parson's Green, ¾ mile R., to Fulham Hospital, on the

2nd. Infected house. (5 and 6) Two from Russell's Cottages, ¾ mile R., to Hampstead Hospital, on the 3rd and 14th. (7) One from 24, Ancill Street, 1 mile R., to Hampstead Hospital, on the 18th. (8 to 16) Nine were from O. S. A., viz., 4 from Wilson Road, and 1 each from Union Place, Hunt Street, Mortimer Terrace, Faroe Street, and King Street.

Kensington Cases.—(1) One from 47, Ifield Road, C. C., to Fulham Hospital on the 10th. The names Ifield Road and Adrian Terrace are indiscriminately used, as they form one street and the houses numbered consecutively. We know of cases of small-pox in this street, as some medical men had asked us to attend them. (2) An attendant at South Kensington Museum, from 146, Adrian Terrace, C. C., on the 15th, to Fulham Hospital. She believed she took the disease from the place of her service. She became a centre of infection to several cases. (3 to 6) Four children from 7, St. Mark's Road, just outside C. C., 3 on the 17th to Fulham Hospital, and the primary case, a convalescent, the following day. The family had recently come to reside here from Bedfordshire, and the previous inmates left the house infected. (7) One from 16, South Street, C. C., to Fulham Hospital, on the 26th. Close to the above cases. (8) One from 3, North Street, C. C., to Fulham Hospital, on the 27th. Close to the above cases. (19) One from 19, Redcliffe Mews, ½ mile R., to Fulham Hospital, on the 15th. (20) A dressmaker from 21, Seymour Place, ½ mile R., to Fulham Hospital, on the 21st. (21) A domestic from 40, Harcourt Terrace, ½ mile R., to Fulham Hospital, on the 24th. (22) One from 46, Fulham Road, ½ mile R., on the 7th, to Hampstead Hospital. (23) One from 17, Ashley Cottages, ¾ mile R., to Fulham Hospital, on the 5th. (24) A domestic from 144, Fulham Road, ¾ mile R., to Fulham Hospital, on the 26th. (25) One from 58, Pembroke Road, 1 mile R., to Fulham Hospital, on the 2nd. (26) One from Providence Terrace, 1 mile R., to Fulham Hospital on the 9th. (27 to 44) Twenty-eight cases were from O. S. A. Six children from 9, Testerton Street, 3 from three infected houses in Southam Street, 3 from three houses in Absolm Road, 2 from Tedbury Road, 1 each from Mornington Road, Bute Street, Blythfield Street, Bosworth Road, Elgin Mews, High Street, Godsden Mews, Notting Hill, Bangor Street, Duke's Lane, St. Evan's Street, Portobello Road (infected from Walmer Road), Goldborne Road, and Holland Place.

Chelsea Cases.—(1) One from 25, Limerstone Street, ¾ mile R., to Fulham Hospital, on the 23rd. (2) One from 11, Hobury Street, ¾ mile R., to Fulham Hospital, on the 30th. (3 and 4) One each from 83 and 85, Fulham Road, 1 mile R., on the 7th and 9th. (5 to 24) Twenty cases were from O. S. A. Two from an infected house in First Street, 2 from Flood Street, 2 from Manor Gardens, 2 from Marlborough Place, 1 each from King's Road, York Terrace, Regent Street, Blackland Terrace, Bywater Street, Ive Street, The Barge, Kensal Town (infected), Paradise Walk (an infected house), Christchurch Street, King Street, Stewart's Grove, and 1 wandering about the street.

July.—Fulham Hospital admitted 67 acute cases, viz., 3 from Fulham, 45 from Kensington, 9 from Chelsea, 7 from Wandsworth, and 3 from Westminster. Highgate Hospital admitted 3 from Fulham, 1 from Kensington, and 1 from Chelsea. Dr. Dudfield, in his Monthly Report, No. 7, dated 25th July, gives 43 fresh cases during the previous four weeks, of which 5 were treated at home. The Medical Officer of Health for Chelsea gives 23 cases as the incidence of the disease in his parish. During the month there were 4 convalescents transferred to Fulham Hospital, and the weekly number of cases were 65, 68, 59, and 52.

Fulham Cases.—(1) One from 2, Wellington Road, ½ mile R., on the 2nd. (2) One from 6, Wilson's Cottages, ¾ mile R., on the 19th. (3) One from 2, King's Road, ¾ mile R., on the 25th. (4 to 6) Three from O. S. A.; 1 each from Victoria Cottages, Oak Terrace, and Munden Street.

Kensington Cases.—(1 to 5) Five cases from Ifield Road, C. C. They were 1 each from Nos. 64, 76, 21, 116, and 93, to Fulham Hospital, on the 7th, 9th, 9th, 11th, and 30th respectively. The last case was that of a domestic, who up to a fortnight of her illness was in the service of a foreign family in Pembroke Gardens, where a fatal concealed case of small-pox occurred which led to the breaking up of the household, and the servant came home at the above address. (6 to 8) Three from Finborough Road, C. C., to Fulham Hospital. A domestic from No. 1, on the 9th. A schoolmaster, who had several children under him suffering from so-called chicken-pox. A landlady from No. 172. One of her lodgers, a clerk in the City, took the disease lightly from his affianced (the second Kensington case for June), followed his daily occupation as usual. A domestic was taken ill, and sent home. Other light cases occurred in the same street, and they succeeded in evading the sanitary authorities. (9) One from 21, Seymour Place, ½ mile R., to Fulham Hospital, on the 8th (case last month). (10) A shop-boy from 238, Fulham Road, ½ mile R., to Fulham Hospital, on the 8th. (11 and 12) A butler from 82 and a domestic from 71, Redcliffe Gardens, ½ mile R., to Fulham Hospital, on the 13th and 26th respectively. (13) A butler from 14, Redcliffe Square, ½ mile R., to Fulham Hospital, on the 29th. (14 and 15) One from No. 2 and one from No. 11, Coleherne Mews, ½ mile R., to Fulham Hospital, on the 30th. (16) A domestic from 2, Cathcart Road, ½ mile R., to Fulham Hospital, on the 30th. A concealed case was treated at home. (17) A female from 8, Clifton Place, ¾ mile R., to Fulham Hospital, on the 28th. (18) One from 2, Cranley Mews, 1 mile R., to Fulham Hospital, on the 30th. (19 to 46) Twenty-eight were from O. S. A., eleven of which were from 29, Wheatstone Road. Dr. Dudfield reported on these cases as follows:—"Twenty-one persons lived in the house—viz., three families in the parlour, first and second floors, respectively, besides a single man in the kitchen who had had small-pox previously. The disease made its appearance in the parlour floor of the house some time in June, the first case being that of a girl aged 10. The parents of this child attempted to conceal the nature of the disease, even from the father's brother, who lived on the first floor, and who has been the greatest sufferer from the outbreak. No preventive measures were taken to check the spread of the disease. On 19th June the suspicion entertained that the child had small-pox was communicated to us in an anonymous letter. The house was visited the same day, and the suspicion proved to be just. In three rooms there lived the parents and two children. The sick girl was in a room by herself, and the mother was nursing her. An absolute refusal was returned to Inspector Langman's urgent and repeated requests that the child might be sent to the hospital, it not being a case in which the compulsory powers of removal could be enforced. Other cases, to the number of 10, subsequently occurred, and these, with one exception, which was very light and was concealed from us, were sent to the Fulham Hospital. Of the 21 inmates of the house, 11 were attacked and four have died, including one adult, the father of the little girl who was first taken ill and who has recovered. This child, it is stated, was running about for days with the scabs of the disease on her face; and it is said, moreover, that the blankets in which she lay, covered with scabs, were hung over the yard wall, a mode of exposure of an infected thing which your Vestry's Law and Parliamentary Committee have advised is not an offence within the meaning of the

38th Section of the Sanitary Act, 1866. At the rear of the house in which these people lived, two other cases have occurred in other two houses, the disease apparently having been spread by the exposure of the before-mentioned blankets, which, by the way, first excited suspicion as to the nature of the illness." One each from Bosworth Road, Lionel Mews, Angola Mews, Lonsdale Road, Upper Westbourne Park, Rabbit Row, Swinbrook Road, James Street, James Place, Goldborne Road, Vicarage Street, Drayton Mews, Kensington Square, Monro Mews (back of 29, Wheatstone Road), Ladbroke Grove Road, Bevington Road, and Southam Street.

Chelsea Cases.—(1) One from 10, Maude Grove, ½ mile R., to Hampstead Hospital, on 10th. (2) One from 27, Slaidburn Street, ¾ mile R., to Fulham Hospital, on the 7th. (3) One from 10, Callow Street, ¾ mile R., to Fulham Hospital, on the 11th. (4) One from King's Arms, Cheyne Walk, 1 mile R., on the 23rd. The lady of the public-house lying ill at home with small-pox (5 to 8) Four from O. S. A., 1 each from Exeter Street, Flood Street, Cornwall Cottage, Kensal New Town, and Hilda Terrace.

August.—Fulham Hospital, admitted 43 acute cases, viz., 2 from Fulham, 24 from Kensington, 7 from Chelsea, 8 from Wandsworth, and 2 from Westminster. Highgate Hospital, admitted 14 from Fulham, and none from Kensington and Chelsea. Dr. Dudfield in his Monthly Report, No. 8, dated 22nd August, reported 39 fresh cases, and 2 deaths; 7 cases were treated at home. The Medical Officer of Health for Chelsea recorded 7 fresh cases. There were 64, 60, 48, and 38 cases under treatment at Fulham Hospital, during each week of the month.

Fulham Cases.—(1) One from 5 Lillie Yard, C. C., to Hampstead Hospital, on the 2nd. (2) A female, from 6, Augustus Place, ½ mile R., on the 6th, to Fulham Hospital. She was sent home ill from the place of her service, outside the parish. (3) One from 36, Peterboro' Road, ½ mile R., on the 18th. (4) One from 3, Dawes' Buildings, ½ mile R., on the 29th. (5 to 10) Six from Rectory Place, ¾ mile R. It was an outbreak of 14 known cases. A servant girl was sent home ill from a shop-house in Fulham Road, at the corner of the Ifield Road; she gave the disease to 1 in 12, Rectory Place, to Fulham Hospital, on the 6th, 1 in No. 14, 3 in No. 34, and 1 in No. 25; sent to Hampstead Hospital; 7 cases were treated at home. (11) One from Stamford Road, ½ mile R., on the 1st. (12 to 16) Five from O. S. A., viz., 1 each from Fulham Board of Works Premises (infected while removing cases to Hospitals), Ivy Cottage, Broomhouse, Orchard Street, and Dolling Street.

Kensington Cases.—(1) A domestic from Cemetery Lodge, C. C., to Fulham Hospital, on the 3rd. (2 and 3) One from 69, and 1 from 124, Ifield Road, C. C., to Fulham Hospital, on the 4th and 5th. (4) A domestic from 44, Finborough Road, C. C., to Fulham Hospital, on the 13th. By visiting her uncle in Langston Street, Chelsea. (5) One from 16, St. Mark's Road, just outside C. C., to Fulham Hospital, on the 2nd. Small-pox in the street since May. (6) A domestic from 67, Redcliffe Gardens, ½ mile R., to Fulham Hospital, on the 2nd. (7) One from 7, Stamford Cottages, ½ mile R., to Fulham Hospital, on the 23rd. (8) One from 45, Thistle Grove, ¾ mile R., to Fulham Hospital, about the 25th. (9) One from Onslow Works, ¾ mile R., to Fulham Hospital, on the 31st. (10) An ironer from 6, Warwick Street, 1 mile R., to Fulham Hospital, on the 3rd. (11 to 24) Fourteen cases from O. S. A. Four from 14, Monro Mews, took the disease from 29, Wheatstone Road, admitted last month, 2 from 8, St. James' Place, a case from the same house last month, 1 each from Bangor Street, Alveston Mews, Bolton Road, Bomore Road, Southam Street, Thorpe Mews, Edwardes Cottages, and Katherine Road. Most of these streets have been infected.

Chelsea Cases.—(1) One from 4, Maude Grove, ½ mile R., to Fulham Hospital, on the 8th. (2) One from 443, King's Road, 1 mile R., to Fulham Hospital, on the 6th. (3 to 7) Five from O. S. A., 2 from Manor Gardens, on the 19th and 31st, 1 each from Langston Street, Pond Terrace, and Marlborough Place.

September.—Fulham Hospital admitted 27 acute cases, viz., 7 from Fulham, 9 from Kensington, 4 from Chelsea, 4 from Westminster, 1 from St. George's, and 2 from Wandsworth. Highgate Hospital admitted 2 from Fulham, and 2 from Chelsea. Dr. Dudfield in his Monthly Report, No. 9, dated 19th September, gives 12 fresh cases, and 1 death of an imported case. The Medical Officer of Health for Chelsea gives 6 cases. The number of cases under treatment during each week of the month were 37, 28, 19, 23, and 28.

Fulham Cases.—(1) One from 4, Seagrove Road, C. C., to Hampstead Hospital, on the 21st. An infected house. Cases from C. C. were sent to Hampstead Hospital to avoid all inquiries. (2) An unvaccinated child from 50, Fawn Lane, C. C., to Fulham Hospital, on the 28th. An infected street. (3) One from 21, St. Thomas' Road, ½ mile R., to Fulham Hospital, on the 14th. She had been to the seaside and returned home ill. (4) One from 26, Rectory Place, ¾ mile R., to Hampstead Hospital on the 6th. Source of the outbreak given in the statement of the last month. (5 to 9) Five from O. S. A. Four unvaccinated children from Munden Street, and 1 from Wilson Road.

Kensington Cases.—(1) One from 132, Ifield Road, C. C., to Fulham Hospital, on the 12th. (2 and 3) Two from 58, Seymour Place, ½ mile R., to Fulham Hospital, on the 18th and 26th. A lady in the house treated for small-pox. (4 and 5) Two from 23, Ashley Cottages, ¾ mile R., to Fulham Hospital, on the 23rd and 25th. (6) One from 2, South Bank Villas, 1 mile R., to Fulham Hospital, on the 27th. Infected in Putney. (7 to 9) Three from O. S. A. Two from Warmington Road. An infected house. One from 2, Bolton Road. An infected street.

Chelsea Cases.—(1) One from 20, Poulton Square, 1 mile R., to Fulham Hospital, on the 29th. (2 to 6) Five from O. S. A.; 2 from College Street (infected in Marylebone), 1 from Robert Street, and 1 from Victoria Hospital (both infected in the hospital), and 1 from Police Station.

October.—Fulham Hospital admitted 9 acute cases, viz., 5 from Fulham, 3 from Kensington, and 1 from Chelsea, up to the 15th, as it was then closed for acute cases. The Metropolitan Asylums Board Hospitals had admitted 10 from Fulham, 13 from Kensington, and 24 from Chelsea, from 6th October to 3rd November. Highgate Hospital had admitted 1 from Chelsea. The cases under treatment at Fulham Hospital were 21, 19, 14, and 13 during each week of the month.

Fulham Cases.—(1) One from 11, St. Thomas's Road, ½ mile R., to Fulham Hospital, on the 2nd. Small-pox in the street. (2) A female from the "Elms," ¾ mile R., to Fulham Hospital, on the 10th. She took the disease from her friends in Clyde Road, ½ mile R., where there were cases of small-pox. (3) A schoolboy from 14, Grove Terrace, ¾ mile R., on the 15th. (4 and 5) Two brothers from 8, Caroline Terrace, O. S. A., to Fulham Hospital, on the 9th. Their sister came home ill from King's Road, Chelsea, three weeks previous, and now convalescent. Cases admitted to other metropolitan hospitals from Fulham during October, November, and December are not available.

Kensington Cases.—(1) One from 166, Adrian Terrace, C. C., to Fulham Hospital, on the 12th. (2) One from 2, Southbank Villas, ¾ mile R., to Fulham Hospital, on the 7th. Infected House. (3) A domestic, from

23, Ashley Cottages, ¾ mile R., to Fulham Hospital, on the 2nd. Infected House: (4) One from 5, North Street, C. C., to Stockwell Hospital, on the 14th. (5) One from Portland Lodge, ½ mile R., to Stockwell Hospital, on the 18th. (6) One from 9, Walgrove Road, ¾ mile R., to Stockwell Hospital, on the 17th. (7 to 9) Three from Shaftesbury Terrace, 1 mile R., to Stockwell Hospital, on the 12th, 23rd, and 25th.

Chelsea Cases.—(1) A student from St. Mark's College, ½ mile R., to Hampstead Hospital, on the 15th. (2) One from 1, Riley Street, ¾ mile R., to Fulham Hospital, on the 1st. Other Chelsea cases are not available, but we know of more than 20 cases admitted to other hospitals.

November.—Fulham Hospital received 26 convalescents, and had under treatment 7, 21, 16, and 21 cases. The metropolitan hospitals had admitted 4 from Fulham, 2 from Kensington, and 17 from Chelsea. Dr. Dudfield, in his Monthly Report, No. 11, dated 14th November, gives 12 cases from four previous weeks. Medical Officer of Health for Chelsea gives 24 cases. Highgate Hospital admitted 2 from Fulham and 2 from Kensington. They were, one from 24A, King's Road, ½ mile R., and 3, Ebenezer Cottages, ¾ mile R., in Fulham. The two Kensington cases were from Silchester Road and Tavistock Road.

December.—Fulham Hospital admitted 34 convalescents, and there were 24, 27, 24, 24, and 15 under treatment during each week. The other metropolitan hospitals admitted 4 from Fulham, 4 from Kensington, and 27 from Chelsea. Highgate Small-pox Hospital admitted 15 from Fulham and 2 from Kensington. Dr. Dudfield's Monthly Reports, Nos. 12 and 13, give 10 fresh cases during eight weeks, to 9th January, 1878. The Medical Officer of Health for Chelsea gives 27 fresh cases during the month.

Fulham Cases admitted to Highgate Hospital.—(1 and 2) Two from 11, Seagrove Road, C. C., one on the 4th and the other on the 27th. Infected house. (3) One from 1, Peterborough Road, ½ mile R., on the 1st. (4 and 5) Two from Fane Street, ½ mile R., on the 3rd and 4th. (6) One from 47, Estcourt Road, ¾ mile R., on the 15th. (7) One from 10, Hilmer Street, ¾ mile R., on the 30th. (8) One from 12, Dieppe Street, ¾ mile R., on the 17th. (9) One from Star Lane, ¾ mile R., on the 16th. (10 to 15) Six from O. S. A., viz., 2 from Mansion House Street, and 1 each from Munden Street, Shuter's Terrace, Goodson Road, and Southbrook Street. We know that of Kensington cases, 1 from 32, Ifield Road, C. C., and 2 from Walgrove Road, ¾ mile R., and 1 from 10, Edwardes Square, 1 mile R., were admitted to Stockwell Small-pox Hospital.

We learn from the able Report of the late Dr. Barclay on Small-pox in Chelsea, that 5 cases occurred in Durham Terrace, O. S. A., during October, November, and December from the same source; Ormond Row produced 9 cases in October and November from a concealed case, and he states other cases were traced to the same source. In October there were 5 cases from 4 houses, viz., 20, 21 (2 cases), 24, and 57, Slaidburn Street. In November there were 9 cases in 6 houses, viz., 28, 30, 37 (4 cases), 38, 42, and 49, Slaidburn Street. In December there were 4 cases, viz., one each from Nos. 28, 49, 36, and 39. Thus there were 21 cases in October, November, and December from Slaidburn Street, ½ mile R. The history of small-pox in Kensington, Fulham, and Chelsea, as given above, shows:—Firstly, that in those months when it was most prevalent in Fulham, it was least so in Kensington and Chelsea, and *vice versâ*, which would not allow drawing up averages on cases or houses in the three districts put together. Secondly—A large number of cases occurred in October, November, and December, when the Hospital was closed, and the Special Area remained infected through concealed cases. Thirdly—The intercommunication between the hospital-staff, especially the non-resident, and the public was free. Fourthly—The hospital management was defective. Fifthly—The above-mentioned history gives many significant facts which account for the causes of the outbreaks in the locality. Under these circumstances the hypothesis of aërial infection, apart from all other conditions, is incompatible with the facts bearing on the history of the spread of small-pox in Kensington, Fulham, and Chelsea during the year 1877.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

LEEDS GENERAL INFIRMARY.

CASE OF SEPARATION OF THE LOWER EPIPHYSIS OF THE FEMUR.

By A. F. McGILL, F.R.C.S.,
Honorary Surgeon to the Infirmary.

THE patient, a strong, well developed boy, aged 15, was admitted into the Leeds Infirmary on April 5th, 1884. He states that while sitting at his work, with his feet on the ground, centre-punching a boiler plate, the heavy iron plate slipped and struck the lower part of the femur, above the left knee. He was immediately disabled, and was unable to walk; he was straightway brought to the hospital.

When examined he is seen to lie on the left side, with left leg slightly flexed and everted. There is general swelling in the region of the knee-joint and well marked deformity. The anterior surface of the patella lies in a plane 1½ inches in front of the anterior surface of the shaft of the femur; behind the patella can be felt a mass of bone corresponding in shape with the lower epiphysis of the femur; this lies in front of the lower end of the shaft, the articular surface looking downwards and forwards. Posteriorly the broken lower end of the shaft of the femur can be felt; the popliteal vessels are by it displaced backwards, and are felt beating directly under the skin. On measuring it is found that the circumference of the injured limb opposite the upper border of the patella is 14⅞ inches, on the other side it being 13 inches; the ilio-patellar line is shortened five-eighths of an inch. Pulsation in the posterior tibial and dorsal arteries is unimpaired.

Ether having been administered, the deformity in the limb was easily reduced by forcibly flexing the leg till the heel touched the buttock. The limb was placed on a back splint, and the patient made a perfect recovery.

Remarks.—The above case is an example of a rare accident, which has often led to loss of life or limb. If not reduced the leg is of but little use, and the popliteal vessels may be so injured as to give rise to a traumatic aneurysm, or to gangrene of the foot and leg. A specimen in the Leeds School of Medicine Museum, taken from a limb amputated for spreading gangrene, shows the exact nature of the accident; the lower epiphysis is displaced upwards and forwards in front of the shaft and rotated forwards on its transverse axis; the popliteal vessels were in this case entirely occluded by the pressure of the lower broken end of the femur.

The displacement of the epiphysis forwards is not, perhaps, what might have been expected; it is accounted for by the fact that the epiphyseal line slants obliquely from above and in front, downwards and backwards.

LEEDS FEVER HOSPITAL.

CASES OF ENTERIC FEVER, WITH SUPPURATIVE PAROTITIS.

(Under the care of Dr. BARRS.)

Case 1.—Eliza W., aged 25, a woolworker, was admitted on October 11th, 1883, in about the middle of the second week of a fairly severe attack of enteric fever. Up to October 23rd, about the twenty-first day of the disease, the case pursued an ordinary but anxious course, the temperature curve running at a mean of 103·5° Fahr., with very free diarrhœa. On the evening of October 23rd a swelling on each side of the face was first noticed, and on the morning of the 24th had attained considerable size. The fauces were injected, but there was no ulceration or swelling. On the 25th the swelling had reached enormous dimensions, extending downwards, on the sides of the neck and beneath the chin; the eyelids were œdematous, and the features much distorted by the extreme widening of the face. There was an offensive metallic odour of the breath and some difficulty in swallowing and breathing. Temperature, 102·8°, morning and evening; pulse, 172. She died the following morning.

Necropsy.—The parotid glands and adjacent connective tissue were much inflamed. Section showed intense œdema of gland tissue, with hyperæmia and very general purulent infiltration, the whole of the parotid body being soaked with pus. The intestines showed extensive typhoid lesions of the lower third of the ileum. In some of the ulcers the sloughs had separated, but in others they were still adherent. The spleen weighed five ounces. No other changes of importance found.

Case 2.—Eliza S., aged 21, was admitted on November 24th, in the early part of the third week of typhoid fever. The case ran an unusually severe course, with profuse diarrhœa and recurring small hæmorrhages until December 2nd. On December 2nd the right side of the face and neck began to swell, soon followed by the left side; the temperature rose to 104·2° Fahr. On December 3rd the swelling had much increased, and extended to the submental region. The local condition remained unchanged until the 7th, when the swelling in the parotid and submaxillary regions considerably diminished, and had become softer and more elastic, but there was no appearance of pointing. The skin was freely movable over the swellings. On the 11th the swelling on the right side had very much subsided, and the submaxillary swelling on this side had quite disappeared. The swelling on the left side gradually increased till the 16th, when it was incised and a quantity of thick pus liberated. The temperature curve never rose during the attack of parotitis above 102°, but the patient became extremely feeble with involuntary evacuations and the formation of acute sacral bed-sore. Convalescence, which is only now (May 3rd) completed, was very seriously interrupted by two severe attacks of erysipelas of the head and face, and one relapse of the enteric condition, and by the formation of many bed-sores, in spite of every precaution. The benefit derived from forced feeding in the later stages of this case was unusually striking, bed-sores, which had been at a standstill for weeks, healing with the most gratifying rapidity.

The above brief abstracts are taken from the detailed reports of Dr. Crooke, the Resident Medical Officer.

Medical Times and Gazette.

SATURDAY, MAY 24, 1884.

It is an annual occurrence at the concluding meeting of the session of the Pathological Society that there should be more business than can possibly be transacted, and last Tuesday formed no exception to the rule. Amongst the crowd of card specimens one especially deserves notice. Mr. Morgan showed the cerebellum and atlo-occipital joint of a child who had come by its death in an unusual manner. The child fell on the stairs at a moment when it had a knitting needle in its mouth; the needle was driven through the palate and through the atlo-occipital joint into the cerebellum. It was at once extracted, but the child died in about twenty-four hours.

Aneurysms monopolised a good deal of the time, Dr. Turner exhibiting several specimens of cerebral aneurysm. His contention was, if we understood him aright, that miliary aneurysms are not so common as some authors would have us believe, and that it is not to this cause that we must attribute the majority of cases of fatal hæmorrhage into the brain. He admits a local dilatation of the arterioles as a result of arteritis, which is liable to have a weak spot somewhere, but does not regard such dilatation as aneurysmal in its nature. Dr. Percy Kidd brought a series of cases of pulmonary aneurysms, *i.e.*, developed on branches of the pulmonary artery, by reason of the formation of cavities and of the loss of support to the wall of the vessel thereby occasioned. He showed very clearly that this condition is by far the most fertile cause of death from hæmoptysis, an opinion which Dr. Wilks afterwards expressed even more strongly. They do not, however, always give rise to hæmoptysis, as no less than six of his cases had died without presenting this symptom.

A valuable paper was almost thrown away in being communicated at this meeting, by Messrs. Parker and Shattock, on the mode of production of the various forms of congenital talipes. The authors were only able to give the briefest outlines of the results of their work, and it is impossible to discuss the correctness or otherwise of their conclusions without a fuller knowledge of the observations on which those opinions were arrived at. Dr. Sharkey showed an unusual specimen of ulceration of the intestines, certainly not tubercular, and not due to typhoid. There was nothing in the case, so far as we were able to gather, that pointed to syphilis, either inherited or acquired; but why may not the ulceration have been simple? We do not class all ulcers of the skin as tubercular or syphilitic, and we recognise a simple ulcer of the stomach. There does not seem to be any *a priori* reason why we should not have a simple ulceration of the intestines.

At the meeting of the Royal Medical and Chirurgical Society on Tuesday next, May 27th, two papers by

Dr. Cayley and Dr. Biss will be read on the treatment of cavity of the lung by paracentesis. Several of those who have experience in this method will attend, and a very interesting discussion is expected.

Speaking at the meeting of the Hospitals Association on Wednesday evening, Mr. Burdett urged a fusion of the Metropolitan Sunday and Saturday Funds as being called for on several grounds. After admitting that they have proved very useful in the past, and after refuting the commonly propagated doctrine that since their institution the amounts received by the hospitals, in ordinary subscriptions, have shown a marked falling off, he proceeded to indicate the reforms which he considered to be needed, if these great organisations were to work all the good they were capable of. The amalgamation would save a very considerable amount of money now spent in advertising, and collecting the two funds separately, and would, Mr. Burdett thinks, really lead to greater receipts, if the collections were made on consecutive days, as a spirit of rivalry would be engendered, which should stimulate all parties. We do not feel quite so sure of the wisdom of this proposal; many people who now give to both, would not feel inclined to subscribe on two consecutive days. But the chief feature of the paper was to call attention to the great expense incurred in the management of the Hospital Saturday Fund, the working expenses of which exceed nineteen per cent. of the receipts, nearly three times as much as a similar institution at Birmingham. This lack of economy Mr. Burdett traces to the same motives which prompt the executive to demand from the hospitals a *quid pro quo* return, in the shape of letters for the amount received from the fund. Against this system he protests in vigorous, but none too strong language, and we cordially agree with him that the imposition of such conditions, as a sort of contract with the hospital, is entirely contrary to the spirit of charity, and not creditable to the management of the fund.

In a recent communication to the Academy of Medicine in Ireland, Dr. C. A. Cameron recorded the results of some experiments he had carried out, to determine if possible why some vaults beneath one of the churches in Dublin were possessed of antiseptic properties. Some tubes containing infusion of melon, which had been carefully sterilised, were placed in the vault for six weeks. At the end of this time five were turbid and filled with mycelium, and five were perfectly clear, but became turbid after they had been in the laboratory a short time. The experiment took place in August, and Dr. Cameron considers it of interest that an unstable organic liquid should have remained so long undecomposed.

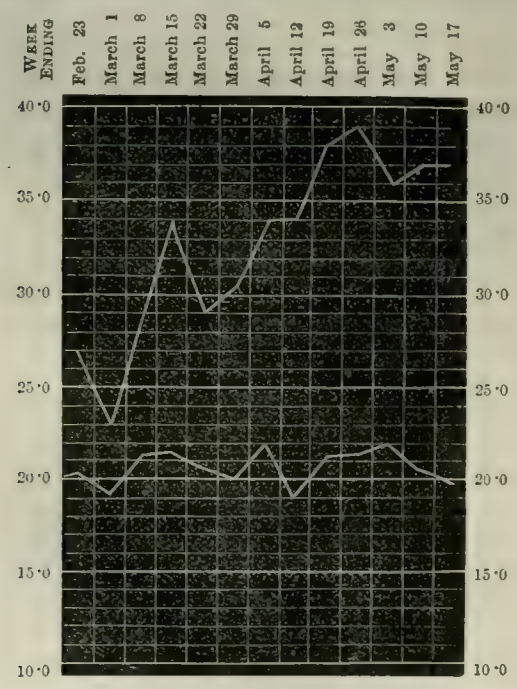
M. Fallières, the French Minister of Public Instruction, has fallen in with M. Pasteur's wish to have the results of his experiments on rabies authoritatively confirmed, and has appointed a very strong Commission for that purpose, comprising the well-known names of Brelard, Paul Bert, Bouley, Villemin, Vulpian, and Tisserand. M. Pasteur must have felt great confidence in the accuracy of his conclusions to be willing to expose them to such an ordeal. The general complaint hitherto made by other savants against him is that he has shown himself too suspicious of scrutiny, and his results have on that account perhaps met with more scepticism in the scientific world than they deserved. His action on the present occasion therefore deserves to be generously recognised, though it is his results rather than the processes by which he has obtained them that he exposes to scrutiny. Everyone will await with interest the report of the Commission. If it is favourable, and if, further, it should be shown that hydrophobia can be forestalled in man, and rabies stamped out in animals, medical science will have achieved a victory, the brilliancy of which can hardly be overestimated. The actual number of deaths from hydrophobia, it is true, is infinitesimal compared with those from other preventible diseases, but the suffering it causes where it exists, and the apprehension it gives rise to in a thousand cases where it does not exist, would make its annihilation a matter for universal thanksgiving. There are two further considerations that will give additional importance to M. Pasteur's discovery, should it prove to be a genuine one. In the first place, it will immensely stimulate research in connection with analogous diseases, for which it is to be hoped a similar preventive may be found; an attenuated syphilitic virus, for instance, the inoculation of which would infallibly prevent all secondary and tertiary manifestations would rescue thousands from a life of misery. In the second place M. Pasteur's success will be a blow to the anti-vivisection agitation. It will make, or ought to make, every dog-lover the friend of experimental physiology, for even the most rabid anti-vivisectionists must admit that rabid dogs would in all probability have existed to the Greek Kalends if they had had their way in France as well as England.

In the case of Bird *v.* Lord Greville, which came before Mr. Justice Field, on Tuesday, there was once more a deplorable conflict of medical testimony. It is a bold line for any scientific witness to take, to maintain that a house is absolutely free from infection a week after a case of measles has been removed from it, even supposing that the most scientific and thorough disinfection has been carried out in the interval. In the present case the precautions taken were declared by the witnesses for the defendant to have been insufficient, and the judge was no doubt quite right in refusing to believe that all risk of infection had been removed. The plaintiff evidently placed himself in the wrong by not informing the defendant that there was measles in the house before the negotiations for letting it were completed. He ought to have given his tenant the option of breaking off the negotiations, or at any rate of deciding for himself whether the disinfection was carried out to his satisfaction. The decision will, no doubt, make would-be letters of furnished houses more careful, and, it is to be hoped, more candid.

A successful dinner took place at the Holborn Restaurant on the 9th instant, under the Presidency of the Lord Mayor, on behalf of the improvement of the

out-patient department of the Westminster Hospital and the erection of a new medical school. The out-patient department has long been felt to be very inadequate, owing to the small space into which the rooms are crowded. It is decided to proceed as soon as possible with the new building, within a few minutes' walk of the hospital, where ground has been secured on which a thoroughly satisfactory school can be erected. The whole of the lower part of the hospital can then be devoted to the out-patient department. When these improvements are finished, the arrangements for practice and teaching at the Westminster Hospital will be all that can be desired. About 15,000*l.* are necessary to complete the work, which it is hoped will soon be raised. At the dinner the sum of 4,500*l.* was obtained, of which 1,000*l.* was given by the Duke of Westminster.

THOUGH last week the mean temperature of the air in London was as much as 6·5° above the average, and the thermometer never fell below 45°, the total number of deaths was only 12, and the number of deaths from respiratory diseases only 10, below the average. The number of zymotic deaths, on the other hand, was as many as 60 above the average, an excess more than accounted for by the fatal prevalence of measles and whooping-cough. The general death-rate was 19·9, or 0·7 per 1,000 lower than in the previous week, while the zymotic death-rate remained steadily at



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of last quarter, and the past seven weeks of the present quarter.

the same level—3·7. The small-pox epidemic appears to show some signs of abating, only 112 cases having been admitted into hospital during the week, as compared with 266 in the week previous. The deaths from this disease, however, rose from 19 to 30, excluding 12 fatal cases which occurred outside Registration London. Of the whole number of fatal cases 32 belonged to Hackney and East London.

THE returns of the Registrar-Generals of England, Scotland, and Ireland for the first quarter of the present year have just been published, and are on the whole exceptionally favourable. In all the three divisions of the kingdom, both the birth-rate and the death-rate were considerably below the average. In England and Wales the birth-rate, 33·2 per 1,000, was 2·0 below the ten years' average, and lower than in any corresponding quarter since 1850. The death-rate, 19·5 per 1,000, was 3·7 below the ten years' average for the corresponding quarter, and lower than in any winter quarter since civil registration was first commenced. The zymotic death-rate was 2·00 per 1,000, against an average rate of 2·55 in the ten preceding corresponding quarters. In Scotland the general birth-rate for the quarter was 32·1 per 1,000, and the death-rate 19·9, compared with ten years' averages of 34·6 and 23·5 respectively. Unfortunately, the number of zymotic deaths for the whole of Scotland is not given, but only that for the eight large towns, and even here no average for past years is given, so that comparison is impossible. In short, the quarterly return for Scotland compares most unfavourable in respect to completeness with the excellent reports issued from London and Dublin. In Ireland the birth-rate for the quarter, 24·2 per 1,000, was 1·7 below the five years' average, and the death-rate, 19·5, was as much as 3·2 below the average for the same period. The zymotic death-rate was 1·7 per 1,000, a rate comparing very favourably, not only with previous returns from Ireland, but also with the rate for the same quarter in other countries. The same is true of Dublin, which, though it had during the quarter a general death-rate of 26·9 per 1,000, had a zymotic death-rate of only 2·2. This fact makes one inclined to regard the returns with suspicion. It will be seen from the table

PLACES.	Births.		Deaths.		Deaths from Zymotic Diseases.		Percentage of Zymotic Deaths to Total Deaths.
	Total Number.	Rate per 1,000.	Total Number.	Rate per 1,000.	Total Number.	Rate per 1,000	
England and Wales	224,694	33·2	132,097	19·5	13,552	2·00	10·26
Scotland	30,889	32·1	19,115	19·9	—	—	—
Ireland	29,964	24·2	24,119	19·5	1,860	1·70	7·7
Twenty-eight English Towns...	77,354	35·4	46,153	21·1	5,769	2·64	12·2
Eight Scottish Towns ...	11,008	35·7	7,059	22·4	1,140	3·7	16·1
London	34,894	34·8	20,382	20·4	2,699	2·70	13·2
Edinburgh	1,881	30·7	1,260	20·5	221	3·58	17·5
Dublin	2,596	29·6	2,362	26·9	194	2·2	8·6

New York	—	—	8,027	24·2	841	2·4	10·04

that in no other town or district, except Dublin and Ireland, was the proportion of zymotic deaths to the

total deaths less than 10 per cent. In Dublin it was only 8·6 per cent. Is there a possibility of deaths from zymotic disease being more generally overlooked or more frequently registered under other causes in Dublin than elsewhere?

Dr. Yversen's proposal to anæsthetise patients *per rectum* appears likely to have a future. It is claimed that the method is as safe, and as effectual, and not so unpleasant to the patient, as the ordinary method of inhalation. On Dr. Yversen's proposal, Mons. Mollière, of Lyons, tried it in various operations, and with so much success as to encourage the best hopes of its proving really useful. Since the publication of the method, other surgeons appear to have tried it, and in many instances with satisfactory results. The plan of administration is to connect an india-rubber tube with the ether bottle, and to the other extremity a vaginal nozzle is attached, which is introduced into the rectum. The bowels are thoroughly cleansed with a preliminary purge, and the rectum is emptied by an enema shortly before operation. When all is ready the ether bottle is placed in hot water of 140° to 160° F., the temperature varying a little with the amount of ether vapour required: the heat of the water must be kept up. The time required to produce complete anæsthesia appears to vary from six to 30 minutes, and the amount of ether used from two to six ounces. The distension of the bowels with ether vapour appears not to cause any great discomfort: it is quickly absorbed, and can be detected in the patient's breath within a few minutes of the commencement of its exhibition. The period of excitement, which M. Mollière thought was not experienced, appears, however, to be present in many cases, and a fact also not noticed by him, is the occurrence of diarrhœa in a considerable proportion of cases. In one or two, the diarrhœa has been accompanied with the passage of blood, and in one child it is reported that death resulted on the day following the operation, after several large and bloody stools had occurred. It is well, therefore, that surgeons should be put on their guard. Doubtless, experience will soon teach whether the diarrhœa is accidental, or due possibly to the mode of administrating the ether—perhaps, too, a too rapid distension of the bowel with the ether vapour may have to do with it. It must be remembered that the ether vapour once introduced into the intestines cannot be easily withdrawn, and until, therefore, its effects are better known, great caution must be used. The anæsthesia must be produced slowly, that is, the ether must not be placed in too hot water. We shall hope to receive reports as to its mode of action from those who try the method.

Some weeks ago we called attention in a leading article to the dislocation of seasons from which we have been suffering of recent years. The same subject has been treated from a more or less scientific standpoint in a pamphlet recently published in Edinburgh, by Mr. W. Thomson, a well-known authority on viticulture. In this pamphlet he puts forward evidence showing that in recent years there has been a marked deterioration of the seasons, so far as the conditions favouring vegetation are concerned. Trees now refuse to grow where once they flourished vigorously, and fruit crops have shown a marked falling off in the last decade. In many parts the same fruits cannot be grown that were grown forty years ago, and both in North America and Spain the influence of the change of climate on vegetation has been remarked. Mr. Thomson concludes that if the average temperature of the year should sink only a single degree below the point now reached, the depression of the great interest of agriculture will be felt even more seriously than it has been hitherto. The investigation might be extended with advantage to the animal kingdom, and even to the lordly primates. We have already pointed out some of the directions in which a change in the character of the seasons may affect the health of the community. With regard to the first quarter of this year, the vital statistics of which have just been published, the effect on the public health has been all to the good. The mean temperature of the quarter, we learn, was 4·7° and 3·5° above the averages of 113 years and 43 years respectively, while on only three occasions since 1771, has that mean been exceeded, namely, in 1822, 1846, and 1872. As in great measure a result of this, the death rate for the quarter was 3·7 below the mean rate of the ten preceding corresponding quarters and lower than on any winter quarter on record. That means that 33,600 persons survived who would have died with an average death rate. Of course, sooner or later we shall pay for it in one way or another.

The past and present students of Guy's Hospital celebrated their Biennial Festival, on the 13th instant, at the Holborn Restaurant. A very large attendance, and the genial presence of Dr. Braxton Hicks in the chair, combined to render the proceedings thoroughly successful. Many of the speeches were of unusual interest, and, it may be added, of unusual length. Responding to the toast of the Army, Surgeon-Major Hume-Spry seized the opportunity for a vehement vindication of the Army Medical Service during the Egyptian Campaign of 1882, the supposed break-down of which he showed to have been due to the delay of the Transport Department in arriving at Ismailia. The speech of the evening was that in which Dr. Wilks replied to the toast of the Medical School. Alluding to the differences which a few years ago had arisen between the Medical Staff and the Governing Body, he showed conclusively that such temporary difficulties had become inevitable under the then existing regulations and customs. Not only had all difficulties and differences of opinion been thoroughly overcome and set at rest, but a new state of things had arisen, which placed the Hospital in a far better position than before. The Staff were sufficiently represented in the government of the Hospital, the nursing had become established on a satisfactory footing, and the perfect freedom of the students had been preserved. Similar views were expressed on behalf of the governing body by the Treasurer and Mr. Hoare, both of whom acknowledged in graceful terms the value of cordial co-operation between the Hospital and the Medical School. The new system of payment by patients was referred to by more than one speaker, and appeared to

receive general approval, especially when it was announced that both paying and free patients were alike employed for general clinical instruction. The loss which cast so deep a shadow over Guy's last November, naturally gave a tinge of sadness even to these festive proceedings, and the memory of Dr. Hilton Fagge, was present in the minds of all his old colleagues, friends and pupils. The success of the meeting was undoubted, and must be mainly attributed to the energy, courtesy, and enterprise of the Honorary Secretary, Mr. N. Davies-Colley.

Speculation is still rife as to which of the several distinguished candidates for the Cambridge pathological chair will secure the favour of the electors. Meanwhile the friends of the various candidates have quite properly determined that the electors shall be thoroughly informed as to the merits of their respective favourites. Considerably over one hundred University graduates who have been or still are pupils of Mr. Charles Stewart, of St. Thomas's Hospital, have signed a memorial to the electors in which they state that they regard Mr. Stewart's teaching of pathology "with nothing short of enthusiasm, feeling indebted to him not only for the matter which he has taught us, but also for his excellent method, which cannot fail to be of the greatest service to us throughout life, no less in all other than in pathological studies." The fact that sixty-six of the signatories are old Cambridge men may be expected to weigh considerably with the electors. We also hear that another of the candidates —Professor Hamilton, of Aberdeen University—is to be presented next week with a testimonial which is being largely signed by graduates and students all over the country who have been at one time his pupils.

Our Vienna correspondent informs us that at a recent meeting of the Vienna Society of Physicians, Dr. Weinlechner showed to the Society an enormous lipoma, weighing nearly four pounds, which he had removed from the inner side of the left thigh of a man, aged 27. The lipoma measured ten inches by seven, was two and a half inches thick, and was situated between the muscles. As long as the patient was in a state of rest, the lipoma formed a large swelling behind the adductors, which extended as far as the popliteal space, and after its removal there remained a large cavity, at the bottom of which the femoral artery and vein were to be seen quite bare. The more the muscles contracted, the further the lipoma disappeared into the sub-muscular stratum. The removal was easy, and there is nothing particular to be recorded about it. On cutting through the tumour, several round brown nodules of the size of walnuts were discovered, consisting of fat and partially calcified, especially at their circumference. One of these knobs, which was evidently due to a disintegrating process, presented a cavity which contained a thick brown fluid, resembling fat, and consisting in great part of that substance, according to the result of an examination by Professor Ludwig. The smaller nodules, which were in part calcified, were very hard, on account of excessive development of tissue in them. If the larger nodule which contained liquid fat had been punctured before the operation, there would have been great doubt as to the diagnosis.

In the aquarium of the Health Exhibition, the biological student has a fine opportunity of studying the fungus disease of fresh water fish. Professor Huxley, in his investigations on the salmon disease, identified the fungus as an ordinary pathogenic Saprolegnier; it is composed of a mycelium consisting of a feltwork of fine tubular filaments or hyphæ; many of the hyphæ are terminated by elongated oval enlargments or zoosporangia, within the latter are the zoospores, which escape through the apex of the zoosporangia and being actively or passively dispersed through the water, plant themselves as it were on dead or living animal substances. The tanks containing the bream, roach, pike and carp are more particularly affected. Grey patches of a down-like material are seen on the back, sides, and head of many of the fish, one large roach is almost encased by it, a pike has a heavy fringe like a beard attached to the lower jaw, and almost the whole of the scales hidden by miniature jungles of hyphæ. Owing to the ravages of this disease, without doubt there will be considerable mortality among the fish during the next few months.

A case of fraudulent manipulation of a thermometer producing great elevation of the mercury is reported from France. Dr. du Cartol brought this case before the Hospital Medical Society of Paris on April 25th, in order to show the part played by simulation in the production of these phenomena. This has often been shown before, and the case is chiefly remarkable for the careless observation which rendered the repeated occurrence of the high readings possible. An hysterical girl frightened the doctors by frequently presenting temperatures, according to the thermometric observations, of great elevation, *e.g.*, up to 118° F. with a clinical thermometer, and as high as 160° and 212° F. with an ordinary instrument. Although for long after the high registrations had been first observed she was placed under a "strict system of watching," it was not till after the trouble had been taken of procuring more thermometers that, according to the reporter, the watching was "crowned with success." It was then found that the girl had procured these results by reiterated percussion of the free end of the thermometrical tube. It seems hardly conceivable that an observer really on the alert, as every one should be with an hysterical patient, and concerned with such a matter as these abnormally high temperatures, should not at the outset have rendered all manipulation of the instrument by the patient impossible, at the same time removing all possible causes of artificial heat. We are reminded by this case of a similar one brought before the Clinical Society a few years ago when the patient, after a long continued series of abnormally high temperatures, confessed that she had inserted the thermometer into hot poultices.

It is of course difficult to eliminate *all* possible means of fraud in these cases, but there are obvious precautions to be taken without which the publication of such a case as the above is a waste of time.

It is not, however, to be inferred from these clear cases of fraud that the same explanation can be applied to all reported cases of paradoxical temperatures. Some cases remain, as those which have been detailed by Mr. Teale, Dr. Donkin, and others, where all fraudulent methods of obtaining these results were completely out of the question. Certain physical conditions surrounding the bulb of the thermometer (apart from the state of the patient), as explained not long ago by Dr. W. Roberts, of Manchester, may possibly account for some of the reported cases; and imperfectly constructed thermometers will probably account for many more. It is, perhaps, not generally known that the mercury in many thermometers shows extraordinary vagaries at certain parts of the tube—rising correctly up to a certain degree, and above that point being absolutely useless, evincing often an error of many degrees. This can be shown by placing thermometers in warm water, when some of these imperfectly constructed ones will rise several degrees higher than others which are accurate. That jolting or shaking a clinical thermometer will raise the index to almost any attainable height is well known perhaps to every one who is in the habit of carrying one of these instruments in his pocket, especially if it be carried for some time without being used. Still, with all these possible explanations, it would be premature to close the question of paradoxical temperatures, for direct personal observation with several thermometers, when manipulation and artificial heat were definitely excluded, has certainly in some well reported cases, such as those above quoted, made the hypothesis of fraud untenable, and that of thermometrical error somewhat unlikely.

In the *Philadelphia Medical Times*, April 5th, Dr. Formad, Lecturer on Experimental Pathology in the University of Pennsylvania, terminates the publication of an important paper which he read at the Medical Society, and in which he enters upon the most elaborate criticism of Koch's views that has yet appeared. He sums up as follows:—(1) That the bacillus of Koch is a valuable diagnostic sign of tubercular disease. (2) That nothing is proved by its discovery as to the ætiology of tuberculosis. (3) That we are not justified in too readily accepting the bacillus doctrine, such acceptance being likely to do more harm than good. (4) That neither phthisis, nor any form of tuberculosis, is contagious.

In a supplement to the *London Gazette*, published on Wednesday, the promotions awarded by the War Office and Admiralty for distinguished service in the Soudan Campaign were announced. Brigade-Surgeon M'Dowell, who was in medical charge of the expedition, is appointed a Companion of the Bath, and Surgeon-Major Catherwood and Surgeon-Major Wilson, who have hitherto enjoyed the relative rank of Major, are promoted to the relative rank of Lieutenant-Colonel of the Naval Officers' Staff. Surgeon Martin is made a Fleet-Surgeon, and Surgeon H. E. F. Cross is made a Staff-Surgeon. Surgeon Gimlette will be promoted to Staff-Surgeon on April 1st, 1885, a rather unkind date to fix upon.

THE MAJOR PREMISS OF THE MEDICAL REFORMER.

The fascinating belief that lays hold of every fresh advocate of Medical reform, and serves him henceforward as the major premiss of his arguments and the motive power of his advocacy, is—we need hardly say—the belief in the principle of representation. He sees around him Councils and Corporations stricken with what he takes to be either obstinacy, apathy, or blindness, refusing to set out on the path which to him seems so easy and promising. He sees old abuses persisting, vested interests fighting and prevailing against innovation, while the greater interests of the student, the practitioner and the public are forgotten or ignored. He sees the teachers and leaders whom he had learnt to trust and revere allying themselves with obstruction, and stoutly defending the *status quo* as soon as they come within the charmed circle of authority. And so he is driven to place his trust in the only class which has hitherto not been tried and found wanting, and to advocate with fervency the claims of the body of the profession to control the management of their own affairs. And yet the journalist who wishes to be reasonable and temperate, to be faithful to his calling and his profession, and to keep himself free from political, professional or youthful bias, must often find himself asking whether this belief with which he has started is after all a trustworthy one. There are, indeed, facts enough to give him pause. The fact already mentioned, that honest and liberal-minded men, who were once, perhaps, earnest believers in the dogma of representation, are found to surrender it as the years go on, or at any rate come to distrust it so much as to vote against its practical application—this fact alone can hardly fail to influence a man with a reverent as well as a reforming mind. For he cannot with justice attribute all these defections to the numbing influence of age and "place." Then, if he looks at the great body of the profession, he finds most of them entirely indifferent to this pet dogma of his. Some are lost in scientific work, others immersed in the cares of practice, and all, or nearly all, care next to nothing about Medical reform. Again, if he looks at his allies, he finds many of them either manifestly playing for their own hands, or else fighting for hobbies and notions with which he can have no sympathy. He finds himself cheek by jowl with medical advertisers, men who send bulletins and write letters to the lay press, men who run new special hospitals, men who clamour for medical defence, anti-vivisectionists, anti-vaccinationists, palterers with homœopathy and all the tag-rag and bob-tail of the profession. The medical journals, too, which are at one with him in his reform crusade, often hold and advocate opinions on other points which to him seem fatally wrong-headed. Further, if he looks to experience to support his belief, he finds, in the only body which claims to rest on a popular basis, the representative principle reduced to a farce, and the elections as much in the hands of wire-pullers as in the closest Corporations. These are facts sufficient to shake the faith of any young reformer. Are there

other considerations to re-establish him? We think there are.

In the first place—if the action of lay authorities is any argument—the Government, in their Medical Bill, have approved of the application of the representative principle to the medical profession. Should this Bill pass, the Medical Council will be the most representative body connected with the profession, provided always that the election of the direct representatives does not fall, as we dread it may, into the hands of the politicians who govern the British Medical Association. In the second place, it is worth observing that the licensing bodies are liberal and enlightened in exact proportion as they are governed on a popular basis. The University of London, for instance, is more liberal and enlightened than the College of Physicians; the College of Physicians is less conservative than the College of Surgeons, which, in its turn, is revolutionary compared with the Apothecaries' Society. The London University, of course, is at present only partially governed on the principle of direct representation, a large section of the Senate being chosen by the Crown, that is on the indirect representative principle; but Convocation—which all graduates may attend, and not only a higher grade as in the case of the College of Physicians—has a real influence on the policy of the Senate. Of the three Metropolitan Corporations the College in Pall Mall is certainly the most popularly constituted, for the President is chosen by the body of the Fellows, whereas in Lincoln's Inn Fields he is selected by the Council, and at Blackfriars by the date of his baptismal certificate.

But the most important consideration in favour of the representative principle is that it is an educating principle. If we waited to extend a suffrage until the proposed new voters were competent or anxious to vote, reform would tarry till Doomsday. In politics it has been held and proved by experience that the right to vote brings in its train the competency and the wish to vote, and we do not see why it should prove otherwise in the medical profession. If the body of the profession are careless and ignorant about medical politics; if the Members of the College of Surgeons and the Licentiates of the Apothecaries' Society are indifferent as to whether they possess a voice in the management of those Corporations or not, it is simply because representation has hitherto been denied them. Give them a vote, and in a few years' time they will show that they know how to use it. This consideration is in itself sufficient to reanimate the doubting advocate of Medical reform. We want to see the profession directly represented on the Medical Council, and on the governing bodies of the Corporations, not so much for any immediate effect that it would have on the conduct of those bodies, as for the new vigour it would give to medical politics, and the new solidarity it would foster in the profession. The representative principle has only failed, we believe, in the case of the British Medical Association because the interests involved were not important or visible enough to arouse the members from their lethargy. But if real power and important issues were involved, we believe that the profession would soon rise to its new responsibilities. And then the busybodies who now mix themselves up with Medical reform would be lost in the thousands of honest and patriotic voters, and the exercised journalist might retire with contentment, having seen his brightest dreams fulfilled.

OVARIOTOMY IN COWS.

The difficulties which attend the securing and maintenance of an adequate supply of pure fresh milk seem to be felt as keenly by the inhabitants of the large cities of the United States as they long have been by those of our own. If it be true, as stated, that in the City of New York the number of deaths among children under five years of age was reduced by 3,673 in last year below that of 1882 in consequence of improvements effected in the milk supply—"the adulteration having been lessened to the extent of 100,000 quarts daily"—the fact affords a hopeful augury for the future, as well as a suggestive comment on the past. But however great the care used in the initial processes of obtaining and transporting the milk from the cow, and however thorough and costly may be the supervision which is exercised over its subsequent manipulation and distribution; there will always, under present conditions, remain one disturbing element beyond the sphere of human control. Not only is milk a complex mixture of organic substances liable to easily-provoked chemical changes; but its secretion is the result of a highly specialised physiological function, and it is peculiarly subject to perturbations of quality in connection with variations in the life processes of the animal which yields it.

A cow giving fourteen quarts a day when she "comes in" would be accounted a good one; every two or three weeks there will occur a perceptible alteration in the quality and character of her milk, and this change will last for a few days, after which she will yield rather less than before. At the end of ten months she will be giving only some three or four quarts of milk, and this of a kind not suitable for use, so that she must be dried off and not milked for the remaining two months of the year. In other words, under most favourable circumstances, such an animal would yield an average of nine quarts a day for ten months and none during the other two months—or a total of 2,736 quarts a year, and this subject to the periodical changes in quality which have been alluded to.

A means whereby the yield may be maintained at a higher average and for an indefinite period, and that, without incurring any of the risks attending repeated pregnancy and parturition, while the recurrent *œstrus* with its attendant physiological disturbances is also avoided, would prove a boon alike to the breeder, the farmer, and the milk consumer. Such are the results claimed for the spaying of milch cattle. In this country the operation is sometimes performed on young cattle in order that they may be the earlier and more easily fattened; and it is extensively practised by the great stock-raisers of Texas and elsewhere simply for the purpose of making good beef-cattle, with a loss of but five or six in each thousand animals operated upon. The only points noticed by the butcher

are an improved amount and quality of flesh, some matting of the tissues at the site of the scar, and the absence of the ovaries. But as an operation performed on the adult cow *with the object of increasing the yield of milk and making it persistent*, it is almost, if not quite, unknown in England, though it has been advocated in France, and has been carried out by some farmers during the past twenty years in America, where it is now coming into extended favour.

The operation is not a difficult one. The incision is usually made for convenience sake in the left flank, under a twenty per cent. carbolic spray. The operator having reached and recognised the uterus, is guided by one of its horns to an ovary which is removed by an ecraseur, or by simply twisting it between the thumb-nail and index finger; the second ovary is sought and treated in a similar manner; the external wound is then closed with a few interrupted sutures. The cow is kept in the stall on low diet for two or three days, but is turned out to pasture, quite well, at the end of a week. The milk sometimes dries up for a few days after the operation. The process is represented as being but slightly painful to the animal, signs of discomfort being exhibited only during the preliminary incision of the skin, and while the sutures are being inserted at the close of the operation; the thickness and great toughness of the hide make this latter procedure the most difficult of all. Dr. Mecuen, who has operated on several occasions, goes so far as to say that "while the arm and hand are within the belly of the cow the animal really seems to enjoy it, acting as a dog does when one rubs its head."

The loss of life amongst the animals operated on appears not to exceed five or six per cent. On the other hand, from the time of the animal's recovery, the yield of milk becomes continuous, with but a very slight and gradual decrease in amount from year to year. Thus, a cow spayed when giving ten-and-a-half quarts a day, now yields, after nineteen months of constant milking, nine-and-a-half daily, and is still in full milk. In other words a good cow may be made to average nine quarts a day for every day of the year, thus yielding some 5,110 quarts in the twelve months against the 2,736 which have been already mentioned as obtainable from a very good milker in the natural state and under exceptionally favourable circumstances. Moreover the yield continues at or near this rate for year after year, if the cow remain in good health, and provided she be properly fed and attended to. If overfed, the quantity of milk will lessen, and she will be apt, like all castrated animals, to fatten rapidly, and to develop flesh which is pronounced to be more tender and juicy than ox-beef. Cows thus treated have continued to yield milk, without intermission, for more than eleven years. The milk itself is stated to be rather improved in quality than otherwise, as regards its adaptation to digestion by the human stomach; the percentage of sugar and of fat are increased, and that of the casein slightly diminished, while its keeping quality is maintained at a uniform standard.

Such advantages certainly appear a more than sufficient set-off against the possible dangers of an operation which is admittedly not without risk, but of which one who has had more than two years' practical experience in performing it says that the risk, when the operation is properly performed, is less than in ordinary cases of calving. That the secretion of milk should be in no way practically diminished after removal of the ovaries is a corroboration of the view that the milch-cow of the present day is largely an artificial product, the result of careful treatment and selection carried out during numberless successive generations. Somewhat analogous cases of an excessive development of the mammary function are not unknown amongst certain varieties of the human race. Thus, amongst the Kafirs, whose women are—in this respect at all events—much on a par with the cattle in exchange for which they are bartered to their husbands, it is not rare to meet a mother suckling her third child of some ten months old, while the eldest, a boy of four, still like his brother and sister, draws all his nourishment from the same source. In the early days of the Kimberley Diamond Fields, a considerable proportion of such milk as was then obtainable—"at a price"—owned a similar origin, and it was a beverage on that account altogether abjured by many of the miners.

REVIEWS AND NOTICES OF BOOKS.

A COLLECTIVE INVESTIGATION.[1]

The almost overwhelming flood of fragmentary literature upon a single point in the ætiology of phthisis which has inundated the medical world since the publication of Dr. Koch's discovery, has for the time obliterated the steady-going stream of investigation and thought which takes its rise in the purely clinical features of the disease. At such a time the perusal of a carefully compiled treatise on the different aspects of family phthisis, in relation especially to heredity and life insurance, is of more than ordinary interest. Whilst the fascinating ubiquity of the tubercle bacillus is constantly leading both lay and medical readers to ask themselves how it is possible that they can ever escape the microscopic scourge, it is almost refreshing to turn aside for a time from such speculations and learn from the dry teaching of hard and unbending facts, what the experience of the past has been and what the probabilities of the present and the future. Whether or not bacilli be found in the sputa or the tissues of persons suffering from phthisis, no careful clinical observer will ever venture to diagnose the exact condition of the disease, or endeavour to decide the probability of its future course, without a close and searching enquiry into family history. More particularly is this the case where life insurance is concerned, and throughout the present work, wherever a practical conclusion is evolved from the evidence adduced, the author has been careful to keep this point in view. The scope of the greater part of the work may be briefly described as an analytical enquiry into the evidence with respect to the influence of heredity upon a very large number

[1] Family Phthisis, by Reginald E. Thompson, M.D. Smith, Elder, and Co., London; pp. 238.

of patients admitted into the Brompton Hospital between the years 1855 and 1880. Of these patients, about three-fourths of the number were derived from the metropolitan area. Those cases only have been employed of which full and complete records have been kept. The work is indeed a "collective investigation," in which a guarantee for the scientific value of the facts recorded is given by the conditions under which the observations were made, and by the high professional status of the observers who made them.

That phthisis may be hereditary is no new proposition, but the exact relation which the hereditary bear to the acquired cases is not so clearly defined, and forms one of the chief themes of the earlier part of Dr. Thompson's book. The influence of double or single parental inheritance, of atavism and of other family implications; the different modes of inheritance and the laws which appear to prevail in them, the relation of family inheritance to the business of life insurance, and, finally, the prevention of phthisis in families, are all in turn discussed in the light afforded by voluminous statistical tables. To the possible errors, deficiencies or exaggerations, which are ever liable to creep into calculations founded on statistical evidence, the author shews himself to be keenly alive, and in his earlier chapters he defends at some length the probable trustworthiness of the information given by hospital patients, which he is quite prepared to rank on an equality with, if not higher than, that afforded by applicants for life insurance. The former, as he shrewdly observes, have no motive for concealment of their personal or family infirmities. Without following out the various analytical processes in detail, it will be sufficient for our present purpose if we indicate roughly the main results arrived at by their means. In the non-hereditary form of phthisis, a striking difference is manifest in the course of the disease in males and females respectively. The former are most subject to attack between the ages of 20 and 35, the disease becoming subacute in nearly half the cases, although with a marked tendency to copious hæmorrhage; a striking contrast is presented in the case of females, in whom the attack generally occurs between the twentieth and the twenty-fifth year, the disease becoming acute in half the cases, with much less tendency to hæmorrhage. Comparing these results with those obtained from a similar series of cases of hereditary phthisis, the powers of resistance which appear to be present in the male in the acquired cases are seen to be diminished, the period of attack being earlier, and the number of acute and fatal cases greater. In the females with hereditary phthisis, there is a still greater liability to early attack, the rapidly fatal cases are much more numerous, and a greater tendency to hæmorrhage becomes manifested.

The influence of the paternal and maternal inheritance upon males and females respectively is worked out in a similar manner, and in considering the more complicated question of cross-inheritance these influences are clearly followed out. Atavism, or the transmission of the hereditary influence through a generation which in itself betrays no sign of its burden, is manifest here, as in insanity and some other conditions, and would appear to gain rather than lose in the intensity of its effects. Experience points to the mother as being the more frequent agent in this silent transmission, and especially in cases of hæmorrhage. A chapter on the laws of phthisical inheritance, consisting mainly of an application of the results quoted in the foregoing chapters to certain of the general laws of inheritance propounded by Mr. Darwin, will be read with much interest. As a fitting conclusion to his truly scientific investigations, the author appends some thoroughly practical remarks upon their application to life insurance and to the most effectual means of checking the spread of acquired or inherited phthisis in families. It will thus be seen that a large area of investigation has been covered within the limits of this compact and unpretentious volume. His readers will duly appreciate the statement made by Dr. Thompson in his preface, that the work is the outcome of much time and labour.

ABSTRACTS AND EXTRACTS.

M. PASTEUR ON THE VIRUS OF RABIES.

THE following is a literal translation of the important paper on the virus of rabies communicated to the Paris Académie des Sciences, on Monday evening, by M. Pasteur, and his fellow workers MM. Chamberland and Roux:—

The important fact that certain infective poisons vary in respect to their virulence, and that insusceptibility to a virus may be secured by means of another virus of less intensity, is at the present moment not only an abstract scientific discovery, but has found an application in the domain of practice. Research being once turned in this direction, it is easy to understand how great an interest attaches to investigations into the methods of attenuation appropriate to new viruses. I have the honour, on the present occasion, to bring under the notice of the Academy an advance in this direction, in reference to rabies.

I.—If the poison of rabies be transmitted from the dog to the monkey, and then from monkey to monkey, its virulence diminishes with each inoculation. If the virus, which has been thus enfeebled by inoculation from monkey to monkey, be then re-transmitted to a dog, a rabbit, or a guinea-pig, it still remains attenuated. In other words, the virulence never returns at once to the degree found in the mad dog of the streets.

II.—The virulence of the poison of rabies is increased when it is transmitted from rabbit to rabbit, or from guinea-pig to guinea-pig. When the virulence has thus increased and reached its maximum in the rabbit, the virus still retains this high degree of virulence when transmitted to the dog, and is evidently much more intensely virulent than the virus of the mad dog of the streets. Under these conditions, indeed, the poison is so virulent, that when inoculated into the circulation of a dog, fatal rabies is the invariable result.

III.—Although the virulence of the poison is intensified in its passage from rabbit to rabbit, and from guinea-pig to guinea-pig, it requires many successive inoculations before it recovers its maximum virulence, when it has been previously attenuated in the monkey. Further, the poison found in the mad dog of the streets, which, as I have just said, is far from being of maximum virulence, when it is inoculated in the rabbit, requires to be passed through many individual rabbits before it attains that maximum.

If we apply rationally the results I have just communicated, we can easily render dogs proof against rabies. The investigator may have at his disposal the virus of rabies in different degrees of attenuation; the non-fatal kinds preserving the economy from the effects of the more active and fatal kinds. Let us take an example. We take the virus

of rabies from a rabbit which has died after inoculation by trephining at the end of a period of incubation, exceeding by several days the shortest period of incubation commonly met with in the rabbit. This period invariably occurs between the seventh and eighth day after inoculation by trephining with poison of maximum virulence. The virus from a rabbit, with the longest incubation period, is inoculated, again by trephining, in a second rabbit; the poison from this rabbit in a third. Each time the poison, which is becoming less and less virulent, is communicated to a dog. The latter is at length found capable of resisting a poison of fatal virulence. It becomes, in fact, entirely proof against rabies, when the poison of the mad dog of the streets is introduced into its system, either by intra-venous inoculation or by trephining.

By inoculations with the blood of animals I have been able greatly to simplify the operation of vaccination, and to produce in the dog the most marked insusceptibility to this disease. I shall shortly communicate to the Academy the total result of what I have found in connection with this point.

It will be of considerable interest, both now and up to the distant epoch when rabies has become extinct as the result of vaccination, to be able to prevent the disease developing after bites by rabid dogs. On this point the first experiments that I have made give me the greatest hopes of success. Thanks to the length of the period of incubation of rabies when communicated by the bite of a rabid animal, I have reason to believe that we can with certainty produce a condition of insusceptibility in those who are bitten before the fatal malady is due.

The first results are very favourable to this view, but it will be necessary to repeat the experiments to an infinite extent on all manner of animals, before we shall have the courage to try this mode of prophylaxis on the human subject.

The Academy will understand that, in spite of the confidence inspired by the numerous experiments I have made during the last four years, it is not without apprehension that I now publish facts which point to nothing less than a possible prophylaxis against rabies.

If I had had sufficient material at my disposal, I should have preferred to defer this communication until I had asked some of my colleagues at this Academy and at the Academy of Medicine to examine the conclusions I have just made known. In deference to these scruples and motives, I took the liberty of writing a few days ago to M. Fallières, Minister of Public Instruction, asking him to be good enough to appoint a Commission to whom I might submit the dogs which have been made proof against rabies. The crucial test which I would propose, would consist in the first place in taking from my kennels twenty dogs proof against rabies, and placing them side by side with twenty dogs intended to serve as my witnesses. We should then have these forty animals bitten successively by mad dogs. If the facts which I have enunciated are correct, the twenty dogs which I believe to be proof against the disease would all remain healthy, while the twenty witness dogs would become infected with rabies. In a second and not less conclusive experiment, we should take forty dogs—twenty vaccinated before the Commission, and twenty not vaccinated. The forty dogs would then be inoculated by trephining with the virus of the mad dog of the streets. The twenty vaccinated dogs would be proof against the infection, while the other twenty would all die of rabies, with symptoms either of paralysis or madness.

OBSTETRICS.

The Relation between Ovulation and Menstruation.—A recent number of the *Archiv für Gynäkologie*, contains an account of an elaborate investigation by Professor Leopold, of Dresden, into the relation between ovulation and menstruation, as evidenced by the condition of the corpus luteum at different periods of the menstrual cycle. The author criticises the cases upon which those observers who have advanced opinions on the subject have based them; and he reports a number of *post-mortem* examinations in which the date of the last menstruation was known, and no disease was present of such a nature as to modify the genital functions. From these cases, together with those previously published which stand the test of his criticism, he draws his own conclusions. The question at issue is this:—What is the relation in point of time between the ripening and bursting of a Graafian follicle and the formation of a corpus luteum, on the one hand; and the monthly hæmorrhage from the uterus, on the other? Does a Graafian follicle burst with each menstruation, and if so, when? Is it before, during, or after the flow, or in the inter-menstrual period? The cases examined evidence the following facts. Ripe follicles to all appearance about to burst—*i.e.*, prominent, thinned at the most projecting part, with a ring of vascularity surrounding the thinned point—and also recently ruptured follicles, have been seen at all periods of the menstrual cycle. The bursting of the follicle does not seem to depend upon its size, for large and small have alike been seen showing the signs of impending rupture. A large and small follicle may exist side by side, and the small one burst first, its rupture being sometimes hastened by the pressure of the adjacent larger one. As observation thus shows that ova may be discharged at any period of the menstrual cycle, it follows that a healthy woman who menstruates may conceive at any time. Dr. Leopold finds also, that two or three follicles may ripen simultaneously, and burst at about the same time, or one, being separated from its neighbour only by a very thin septum, may burst into it. This, which our author believes has not been described before, offers one explanation of plural pregnancies. Further, he has observed appearances which show, that follicles may ripen, blood be effused into them, and yet no rupture take place, but the follicle retrogrades without bursting. Dalton has described examples of the same thing. Professor Leopold suggests that we have here a possible explanation of ovarian dysmenorrhœa. Turning to the examination of the corpus luteum, our author summarises the changes in it as follows. The first day we have simply the ruptured follicle filled with blood. About the third day it presents itself as a large cavity full of effused blood. By about the eighth day, a thin border, with a brighter coloured interior, becomes more sharply defined. By the twelfth day the border has become thicker and thrown into folds. By the sixteenth day the colour of the follicle is pale red or yellowish. Towards the twentieth day the nucleus has considerably shrunk, the border is yellower, and has thrown out folds and striæ towards the centre. From the twenty-fourth to the thirty-fifth day there is a pale nucleus with a bright yellow, closely folded capsule. But these descriptions are only true in a very general sense, because between different corpora lutea of the same date there are very wide differences, both as to size and colour. The age of a corpus luteum, therefore, can be only approximately, not exactly, stated. There is a great difference, however, between a "typical" and an "atypical" corpus luteum. The typical corpus luteum is that formed by a follicle which bursts during the menstrual congestion; it is larger, more turgescent with blood, and retrogrades more slowly, than the atypical, *i.e.*, the remains of a follicle bursting in the inter-menstrual period. Menstruation may take place without the bursting of a follicle, and therefore without the formation of a corpus luteum; and the typical corpus luteum may be produced without menstrual hæmorrhage, if the menstrual congestion be present. The menstrual congestion of the uterus, and therefore of the ovaries, precedes the flow by some time; its intensity is dependent on the condition of the general health, and the state of the uterus, especially of its mucous membrane; and its rhythm is liable to be disturbed by many different causes. The *rôle* of the uterus in menstruation is only a passive one; the relation of its periodic bleeding to ovulation may be compared to that of the hands on a clock face to the works within. In short; ovulation may take place without menstruation, and menstruation without ovulation; follicles may burst and ova be discharged at any time, but do so with preponderating frequency under the influence of the vascularity and tension due to the menstrual congestion.

Bipolar Version in Placenta Prævia.—A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie*

contains an article on this subject, by Dr. C. Behm, of Berlin. It is based on cases observed in the clinic of Professor Gusserow. The author's experience of placenta prævia consists of 53 cases, of which the first thirteen were treated by plugging, rupture of the membranes and version by the old "internal" method. They comprised five cases, in which the placenta was completely prævia; five partial or "lateral" (to use Dr. Behm's word), and three marginal. Of the thirteen, four mothers died, that is 30·8 per cent., and of the nine who survived, four suffered from febrile illness during the lying-in. The children were fourteen in number, and ten of them died during or soon after birth, a mortality of 71·4 per cent. These per centages Dr. Behm compares with the statistical statements of other writers, and finds that they represent about an average mortality. The principle of treatment adopted by Dr. Behm, in his latter 40 cases, was that of bimanual version, after the method of Braxton Hicks, as early as possible, one foot being brought down through the os, and the labour then left to be gradually completed by the natural efforts, the pressure of the breech on the cervix being trusted to restrain hæmorrhage. The result was, that he lost not a single mother out of the 40. The infantile mortality was 77·5 per cent. Hofmeier (whose paper we noticed in the *Medical Times and Gazette*, 1883, Vol. i., p. 220, at the time of its appearance), out of 37 cases, treated in a similar way, only lost one mother, but of the children 63 per cent. In Dr. Behm's series of 40 cases, he performed early bipolar version 30 times. In seven the membranes ruptured early, so that version had to be longer delayed, and three were cases of head presentation, in which delivery was left to Nature. The advantages of this plan of treatment, Dr. Behm points out are these:—(1) The necessary intervention is effected early, as soon as the os will admit two fingers, before the mother has lost much blood, or become exhausted. (2) The breech, drawn down upon the os by slight pressure, forms a perfect tampon. (3) As delivery is effected slowly, shock is avoided. As to the technique of the operation, Dr. Behm remarks that two fingers should be introduced through the os. If the cervix will not admit two fingers, it should be dilated with water bags. If the presentation of the placenta be complete, it will be found that it separates most easily on the side nearest to its edge; if the edge cannot be reached, it is best to perforate the placenta. After the breech has been brought into the os uteri, expulsion is best left to Nature. The accoucheur's motto in these cases should be, "haste with patience" (*Eile mit Weile*), haste in turning, patience in extraction. (We confidently call attention to the results of this practice, because we know it to be that advocated by some of the best English accoucheurs.)

Rupture of the Uterus.—In the *New York Medical Journal* for March 1st, Dr. S. Gilbert reports the case of a healthy woman, aged 34, who was attended in her fifth confinement in December, 1883. Labour was tedious and the pains ineffective; the uterine walls seemed abnormally thin, the fœtus appearing to lie just beneath the skin of the abdomen, on an external examination. Ultimately the delivery was effected with great difficulty, the uterus being inert and the child very large; the child presented by the breech, and when the last arm had been brought down, the os "contracted round the neck of the child with the grasp of a vice." The head was extracted in the course of fifteen minutes; as it emerged from the os, a sharp tearing sound was heard and the patient collapsed. The child, a female, was dead. The uterus contracted promptly; but on following up the funis it was found to lead through a rent in the cervix (slightly implicating the uterine wall proper) into the abdominal cavity, whence the placenta was, without much difficulty, removed. Hæmorrhage was profuse, and the patient apparently moribund. Stimulants and ergot were given, and the patient surrounded with hot flat-irons; sulphate of morphia, a quarter of a grain every two hours, unless the patient slept or was entirely free from pain, was ordered; and hot turpentine stupes were applied to the tympanitic abdomen. The morphia was continued in full doses for eleven days; vaginal injections containing carbolic acid two and-a-half per cent. were used night and morning for three weeks, *i.e.* until all discharge ceased. There was great tympanites and tenderness for several days, and the lochia were offensive and contained pus in large quantities; but all bad symptoms gradually subsided, the woman was up in a month, and on February 1st, was quite well. The temperature only once exceeded 103° F. The favourable result of a very serious case is attributed to the good constitution of the patient, to the full and continuous employment of morphia, and to the antiseptic douches.

The Measurement of the Foot as an Index to the Size of the Child.—One main difficulty in the attainment of precision in the determination of the most suitable method of delivery in difficult labour, is that we have no means of exactly estimating, before attempting delivery, the size of the fœtal head. We can measure the pelvis, but not the head; one factor, therefore, of the mechanical problem, is an undetermined quantity. A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains a paper by Dr. Alfred Gönner, of Basel, in which he has made an attempt to overcome this difficulty, so far as head last cases are concerned. His plan is to measure the foot, and from this datum to estimate the size of the child, and, therefore, of the head. He points out that the measurement of the foot is one easily made, and, therefore, that his method has in this respect the advantage over the other modes in which it has been proposed to estimate the size of the child, such as measuring its length, and measuring the distance between the fontanelles. Dr. Gönner has measured and weighed 100 children. He comes to this conclusion, that if the foot measures more than 8 centimetres (nearly 3¼ inches) in length, the child weighs more than 3,000 grammes (about 6 lb. 10 oz.). A foot more than 3¼ inches long, therefore, makes it probable that the child is above the average weight, and that there will be more than usual difficulty in the extraction of the head. If the foot be only 7·6 centimetres (about 3 inches) long, a child of moderate dimensions may be expected; and a foot length of only 7·3 centimetres (a little more than 2¾ inches) would justify us in assuming that the child was premature. It is interesting to note also, that Dr. Gönner finds that the feet of female children are smaller in proportion to the size of the body than those of males. He suggests that the children of the educated classes will probably have relatively smaller feet than those of the labouring classes, but his own field of observation has not supplied him with the materials for testing this point.

The Mechanical Treatment of the Retroverted Adherent Uterus.—In a paper on this subject, published in the *Boston Medical and Surgical Journal*, February 28th, Dr. J. W. Elliot advocates the gradual stretching of the adhesions by carefully-regulated periodical packing of the posterior vaginal *cul de sac*. The patient is placed in the semi-prone—or in the more difficult cases, in the knee-chest—position; a Sims' speculum is passed, and small pledgets of cotton-wool, wrung out in glycerine, are then placed in position with dressing-forceps, each being pressed back as hard as occasion may require with the blade of the speculum, which is held in the left hand. The pressure should be exerted directly backwards into the *cul de sac*, and against the adhesions: if the force is directed too far forwards, the cervix and bladder are merely raised and tilted forward, while the fundus remains fixed and unmoved. Every fourth or fifth pledget is dipped in iodoform, in order to keep the packing sweet. When Douglas' pouch is filled, the vagina is firmly packed with similar tampons. At the outlet of the vagina, the cotton is pressed back towards the rectum so as to avoid pressure on the urethra as it passes beneath the public arch. The last two pieces of cotton should be rather larger than the others, and should be placed to the right and left respectively, so as to wedge the superincumbent mass home, and to sustain its pressure like the stones in an arch. The tightness of the packing must be determined by the conditions of each case. "As a matter of experience, most men pack too loose rather than too tight. Even when there is considerable tenderness a well-fitting, tight packing gives the most relief." Care must,

of course, be taken to stop the packing on the slightest indication of increasing or fresh local peritonitis. Every three or five days the packing should be removed with the patient in the same position; if it was properly applied, the posterior *cul de sac* is found deeper, and the opportunity should be taken for again gauging the position and extent of the more prominent adhesions; another packing is then introduced as before, but the amount of pressure employed may usually be augmented on each occasion "until you pack as hard as you can, unless some contra-indication becomes manifest." When the adhesions are very firm, bits of compressed sponge, wrapped in cotton cloth, are sometimes employed in the place of cotton-wool. The packing must be removed before each menstruation. If the pressure of the packing cause constipation, the bowels must be regulated by a cathartic. The treatment is to be continued until the fundus uteri can be pushed well forward, and held in good position by a pessary. If, however, the adhesions are very resistant, and the patient become somewhat run down, a convenient time to rest is when the fundus has been raised just above the sacral promontory: at this point the uterus can be held for some time with a Thomas' bulb, or with a soft rubber pessary. Dr. Elliot prefers that his patients, if otherwise in fair health, should walk about during the treatment, since in this way the adhesions work loose more quickly. The time required for treatment has varied from one month to three years. The original paper is illustrated with diagrams, and with reports of cases.

Erysipelas Complicating Pregnancy.—Dr. Wardwell relates a case of this in the *American Journal of the Medical Sciences* for April, and refers to twenty-four others which he has found on record. From a review of these, he comes to the following conclusions:— (1) Erysipelas may attack a pregnant woman at any period of pregnancy, and especially during its later stages. (2) It is most often sporadic. (3) The situation of the erysipelas may be on any portion of the body, usually upon the face. (4) The variety may be either cutaneous or phlegmonous, usually the former. (5) Premature labour almost invariably takes place, and usually within forty-eight hours after the initial chill. (6) The tendency of these cases is to recover without uterine inflammation. (7) It is impossible to base a prognosis upon either the position or the variety of the erysipelas. In reference to putting the child to the breast, while in some of these cases this was done without any ill consequences, a case is quoted, as reported by Mr. Scholfield in the *Lancet* of June, 1867, in which there remained no traces of the erysipelas when the child was born. It was put to the breast only after four days, but was attacked with erysipelas, which proved fatal, no recurrence having taken place in the mother.

Sulphate of Copper as an Antiseptic in Obstetrics.—Dr. Charpentier terminates as follows a paper read at the Académie de Médecine (*Union Médicale*, March 6th):— 1. Sulphate of copper in a solution of one per cent. in water, heated to a temperature of from 36° to 38° C., is an antiseptic of the first order which may render signal services in obstetrics. 2. Absolutely inoffensive to the patient, very cheap, and easily managed, it adds to the advantages of a very powerful antiseptic that of being an almost instantaneous disinfectant. 3. Whether employed as a vaginal injection or as an intra-uterine injection, it is absolutely harmless. 4. Possessed of astringent and coagulating properties, it may hereafter be substituted for the perchloride of iron as a hæmostatic, over which it has the advantage of not discolouring the surfaces. 5. The employment of the solution may be continued for the first eight or ten days several times in the 24 hours, without producing any other effect upon the patient than lowering the temperature and diminishing the frequency of the pulse—that is, a rapid amelioration. 6. It is of interest to surgeons to give a trial to this antiseptic, which under some circumstances, and especially in voluminous thrombus of the vulva, has effected a cure without the production of a drop of pus. In a case of fœtid abscess in the urethro-vaginal partition, it at once suppressed the fœtidity and the general symptoms resulting from putrid infection, and that when carbolic acid had failed.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON,

Tuesday, May 20th, 1884.

J. Whitaker Hulke, F.R.S., President, in the Chair.

Reports of the Morbid Growths Committee.

The Secretary read a report by Drs. Payne and Coupland, on Dr. Burney Yeo's specimen of cast from the trachea shown at the last meeting of the Society. They could find no resemblance to the ordinary features of false membrane; but, on the contrary, there was, as suggested by Dr. Yeo, evidence of a vegetable tissue and some pigmentation. They regarded it as a foreign body of a vegetable nature, probably the skin of a grape. The Secretary also read a report by Messrs. Beck and Godlee, on Mr. Lawson's case of congenital tumour of the orbit. They said that they had nothing to add to the description that had already been given by Mr. Milles, and that it appeared to be similar to other congenital tumours in that situation. The Secretary then read a report, also by Messrs. Beck and Godlee, on Mr. Treves' case of supposed actino-mycosis. They had not found anything resembling the fungus of that disease. It was a large celled sarcoma, consisting of round or oval cells mostly, some of the cells were not unlike those seen in cancer, but it nevertheless could not be classed amongst the cancers.

Bromide of Potassium Eruption.

Mr. Tay exhibited for himself and Dr. Stephen Mackenzie some drawings and microscopical preparations from a case of this affection:—A child 11 months old had taken bromide of potassium three times a day for a few days, and then twice a day for ten days. On the ninth day some vesicular spots appeared on the thighs, and the bromide was soon after discontinued. On the twentieth day there were a number of more or less circular elevated spots, with raised margins, and some isolated vesicles containing clear fluid, chiefly on the loins and the backs of the lower extremities. In one month the eruption had subsided, and six weeks after the last dose of medicine had been taken it had disappeared. A portion was removed for microscopical examination, when extensive changes were found. There were pus cells in the corium near the hair follicles and sebaceous glands, and here and there some small isolated cavities. The papillary layer was greatly distended with blood vessels, and there was some extravasation; at a medium depth there was a great deal of cell infiltration, and deeper still there was infiltration around the blood vessels. Some amorphous granular matter was seen in the neighbourhood of the stratum lucidum. The sweat ducts were unaltered. To sum up, there had been a very active hyperæmia of the corium, especially in the papillæ, and therefore exudation had taken place. The infiltration of the corium and the collections of pus explained the elevation of the skin.

The President thought the communication one of great importance, inasmuch as he believed it was the first time that a microscopical examination of the eruption had been made.

Cerebral Aneurysms.

Dr. Charlewood Turner showed two specimens of this kind. The first was the left internal carotid and middle cerebral artery, showing irregularly rounded masses attached to the latter; also irregular enlargements of portions of the chief penetrating branches of the trunk of the artery which supplied the central ganglia, and several minute nodules on some of the finest ramuscules of the larger of the two principal penetrating arteries. The specimen was

obtained from the body of a man, aged 60, who died from an apoplectic seizure. The corpus striatum was extensively lacerated, and there was some blood in the lateral ventricles, the vessels at the base were exceedingly atheromatous, and the kidneys were granular and contracted. The second specimen consisted of the circle of Willis, and of the cerebral arteries connected with it; there were no minute nodules to be seen. It was taken from the body of a man who died in an apoplectic attack; he was a painter, and was known to have been an intemperate man. The right corpus striatum was extensively destroyed, the arteries at the base were atheromatous, and the kidneys were granular. Commenting on these cases, he said he had been led to the opinion that cerebral hæmorrhage was an accident of arteritis affecting the cerebral arterioles to a greater or less extent, and of an intensity at certain points sufficient to so far soften the arterial walls as to cause them to give way under the pressure of the blood, rather than as the result of a defined aneurysmal formation upon the vessels, like that seen in the aorta for instance. He had arrived at these conclusions, partly because miliary aneurysms were not always present, and partly because his examination of these bodies had taught him that there was no evidence of hæmorrhagic extravasation in their immediate neighbourhood. He did not think that there was, in cases of chronic Bright's disease, so much danger of cerebral hæmorrhage from rupture of miliary aneurysms as there was from an aneurysm formed on the aorta or larger arteries. But in all such cases there was, from time to time a liability to the occurrence of arteritis affecting the arterioles of the brain more or less extensively, affecting especially the inner and outer coats, and characterised by nuclear proliferation and swelling, leading to permanent thickening of the walls. This arteritis might be developed with especial intensity at one spot, which might then become softer and liable to yield under pressure, giving rise to aneurysmal bulging, and perhaps to hæmorrhage. Dr. Turner also showed two other specimens: one an aneurysm, the size of a cherry, at the distal end of the basilar artery, taken from the body of a man, aged 52, who died in consequence of its rupture; the other was an aneurysm, about the size of a split pea, on the anterior communicating artery, close to its junction with the anterior cerebral artery; it was taken from the body of a man, aged 33, who died in a state of coma, following on an extravasation of blood into the meninges from the rupture of this aneurysm.

Symmetrical Aneurysms.

Dr. Hadden showed symmetrical aneurysms of the middle cerebral arteries, from a woman, aged 49, who had hemplegia and hemi-anæsthesia. The left ventrical was hypertrophied; no valvular disease. The kidneys contained a few cysts, but were healthy, Blood had been effused at the subarachnoid space all over the brain, due to the rupture of a sacculated aneurysm of the left middle cerebral artery, near the perforating arteries. It had ruptured posteriorly, the blood passing through the roof of the fissure of Sylvius. On right side was an aneurysm from middle cerebral artery at its first bifurcation near the perforating arteries. No evidence of degeneration of the arteries of the circle of Willis. They might have been of embolic origin, but there were no vegetations on the valves, and only slight atheroma of the aorta. Possibly the arterial change was syphilitic, but there was no information on this point.

Pulmonary Aneurysms.

Dr. Percy Kidd showed some specimens, illustrative of the mode of development of aneurysms in pulmonary cavities of acute formation. (1) A case of chronic phthisis in a woman aged 30, who died of hæmoptysis. There was a family history of phthisis. The right lung was universally adherent, and contained scattered small cavities; 22 aneurysms of the pulmonary artery were found in the cavities, varying in size. The walls of the aneurysm were thickened in all instances, and with one solitary exception were not ruptured. Most were at the lower part of the lung. (2) Acute phthisis in a woman aged 26. Two aneurysms, one as large as a pea, both fusiform, were found in an irregular basic cavity with soft caseating walls. The branches of the pulmonary artery were unsupported on all sides, they had not ruptured. (3) Phthisis in a woman aged 26. Trabeculated excavation of the entire left lung. Three unruptured aneurysms were found, their walls were thickened. (4) Chronic phthisis in a man aged 28, death from hæmoptysis. Old cavities in left lung, one at base contained a ruptured fusiform aneurysm, walls rather thin, rupture by linear slit. The aneurysms usually occurred in consequence of the withdrawal of support from the wall of the vessel by the formation of a cavity. They probably commenced with endarteritis, then the other coats became affected, and the middle coat ruptured causing the formation of a thrombus. Adhesion of the lung to the diaphragm probably contributed to the formation of them, by interfering with the free play of the lung. In 230 cases of phthisis, aneurysms were found in 26. In 17 cases rupture had occurred. H moptysis was the cause of death in 21, in one, bronchial ulceration extending into the pulmonary artery, in one it was due to ulceration of an artery, in two the cause could not be found. The walls of the aneurysms were usually thickened, except at the site of rupture. The cavities in which they formed were mostly in the lower two-thirds of the lungs.

Dr. Wilks said that the last statement that fatal hæmorrhage was not due to destruction of lung tissue had been his experience for many years. The hæmorrhage due to rupture of an aneurysm took place in association with the reparative processes that went on; the fatal cases were always those with a long history. Clinical experience and pathological facts were here quite in accord.

Dr. Samuel West thought that one of the most interesting facts brought out by Dr. Kidd was the number of cases in which these aneurysms had occurred without any hæmorrhage.

Multiple Strictures of the Small Intestines.

Dr. Sharkey exhibited this specimen, and said that it was taken from the body of a woman, aged 33, who had died in St. Thomas's Hospital, of facial erysipelas. There was very little family history obtained; she had suffered from indigestion, and came into the hospital suffering from abdominal pain and diarrhœa. There were no physical signs made out by palpation of the abdomen, and the symptoms varied under treatment: there was a little fever in the evenings. On examination the great omentum was found adherent in places to the peritonæum; the liver was fatty, the kidneys were small. The large intestine and the upper part of the small intestine were normal, but in the lower part of the small there were a great many ulcers; they were of two kinds, one small with clean-cut outlines and a non-thickened base; the others much larger, completely encircling the bowel, with a somewhat thickened base, and causing some constriction of the bowel. There was no evidence of tubercle in the peritonæum covering these ulcers, unless a few very minute nodules at one spot could be counted as tubercular. To the naked eye many of the ulcers appeared to have healed. Microscopically there was an infiltration of cells throughout the whole thickness

of the bowel, most marked in the mucous membrane diminishing outwards; these cells showed no tendency to degenerate. There was no tubercle or caseation. The glands and villi were absent. No bacilli had been found in the intestine. The Fallopian tubes showed early tubercular disease. The points which seemed to him noteworthy in these specimens were the number of strictures, their being so near together, the regular and sharply defined character of the ulcers, and the fact that the floor of the ulcers was nearly uniform with the rest of the intestine. As to their nature, the following points were against the idea of tubercle, viz., the absence of tubercle in the peritonæum, the regular outline of the ulcers, and the absence of the microscopical characters of tubercle. The ulcers were not due to typhoid. He thought that the disease of the Fallopian tubes might be clearly regarded as secondary.

Dr. PAYNE asked if there had been any fever.

Dr. MAHOMED asked as to the condition of the mesenteric glands; he also observed that he could see what he considered to be tubercles on the peritonæum.

Mr. TREVES referred to a case where two feet of intestine had been removed during life, and were found in a state of ulceration; a specimen somewhat like the present one was to be seen in St. Thomas's Hospital Museum.

Dr. KIDD asked whether any bacilli had been found in the Fallopian tubes.

Dr. SHARKEY, in reply, said that there had been slight fever. The mesenteric glands were not diseased. As to the peritonæum, if those nodules were tubercles, they were only over one stricture, and it would be most unusual for the peritonæum to be so healthy in tubercular disease. The Fallopian tubes had not been examined for bacilli.

Tumour of Petrous Portion of Temporal Bone.

Mr. CHAVASSE exhibited this specimen. The patient was a woman who had received a blow on the left side of her head, in consequence of which a lump formed and grew. It caused aching pain, deafness, photophobia, pain in the left eye, and paralysis of the facial nerve on that side. The swelling was situated in the parotid region, and extended down the neck, but the movements of the jaw were free. The growth was found to take origin from the petrous portion of the temporal bone, and was removed. The patient did well at first, but died of double pneumonia on the sixteenth day. The tumour was firm, and about half the size of a hazel nut; it consisted of dense fibrous tissue, in which small homogeneous masses with canals were to be seen, and also variously sized deeply staining cells. The parotid was very dense and full of blood vessels. The gland cells were atrophied.

Bilobate Heart in a New-born Child.

Mr. SHATTOCK exhibited this specimen. The superior and inferior venæ cavæ were normally developed, pulmonary veins were confluent on the back of the auricle without having any communication with it. He surmised that the blood from the lungs had been returned through the bronchial or posterior mediastinal veins, communications between which and the pulmonary veins have been shown to exist by Zuckerkandl. The condition tallied with the established embryological fact that the pulmonary venous system is found independently in the lungs, though the manner in which this came to be connected with the heart was not yet determined. Whether the present specimen represented a stage in this process remained to be shown.

The Pathology of Congenital Club-foot.

Mr. R. W. PARKER and Mr. SAMUEL SHATTOCK read a paper on this subject in continuation of a former communication, in which they advocated a mechanical mode of causation for this deformity. Their opinions rested on a careful dissection of five cases (three of varus and two of calcaneus), and on a study of specimens in various London museums. The contention was that there was nothing special in club-foot, nothing which might not be found in other joints. In one of the cases there was histological integrity of the nerve-centres, of the nerve-trunks, and of the muscles of the affected limb, but there was also some extra obliquity in the neck of the astragalus. In another case, however, there was no such malformation in the astragalus. Hence, they argued, the insufficiency of the usually accepted nerve-theory of causation, and of the theory that the deformity depended on the conformation of the astragalus. It was further shown that the conformation of the astragalus which was met with in most cases of talipes was the normal condition in the Simiidæ, although these animals were not talipedic. Thus it appeared that some other cause must be invoked, and they sought it in the environments of the fœtus during intra-uterine life. As additional proofs of pressure (besides the talipes), they related instances of torsion of the bones of the leg and of the astragalus, and also a case in which depressed patches of atrophied skin, with bursæ beneath, were found on the external malleolus and on the head of the astragalus, comparable with what was found in persons who had walked on the unreduced talipedic foot. The varieties of varus and calcaneus were thought to depend on the date of onset, and in both cases were exaggerations of positions normal at some time or other of fœtal life.

Dr. MAHOMED mentioned the case of a child under his care with what he called tetany neonatorum, in which permanent deformities were forming.

Dr. B. O'CONNOR observed that the limbs of babies, though in a flexed condition during the time the child was awake, were yet relaxed in sleep.

Mr. PARKER, in reply, said that they had not wished to make out that all forms were produced in identically the same way. The physiological calcaneus only lasted a few days after birth.

Congenital Xanthelasma.

Dr. BARLOW showed some drawings of a boy, 7 years old, who showed typical shammy leather patches on the eyelids and shoulders, and a cream-coloured staining on the ears, his vaccination scars were also tinted. Xanthelasma was mainly a disease of adult life or old age, but a few cases had been seen in young people, and even congenital cases had been recorded, notably one by Dr. Stephen Mackenzie, where the disease was both congenital and hereditary. Hitherto the congenital cases had differed from the ordinary ones in that the eyelids had escaped, but in the case he showed that evening the eyelids were involved, and, what had also not been before observed in the congenital form, there was some evidence of hepatic affection, inasmuch as the boy had suffered from renal calculus. The boy's father had relapsing psoriasis, and the grandfather had been subject to gout.

Card Specimens.

Dr. SHARKEY. (1) A case of cystic squamous epithelioma. (2) Stricture of stomach and œsophagus with atrophy of stomach.

Mr. CHAVASSE. Tumour of skull.

Mr. SHATTOCK. Unusal condition of hydrocele fluid.

Dr. SILCOCK. Cancer of prostate with secondary ossific deposit in cranium and femur.

Dr. PAYNE for Dr. HANDFIELD JONES. Preparations of pale and red clots in cerebral arteries.

Mr. LOCKWOOD for Surgeon TREVAN, R.N. Chyluria with filariæ in the blood and urine (living).

Dr. HOBSON. Malignant disease of cæcum.

Mr. Morgan. (1) Extensive calcareous deposit in pleura. (2) Perforation of occipito-atloid articulation joint and cerebellum.

Dr. Hebb. (1) A sponge-like liver. (2) The muscular nerves and spinal cord in diphtheritic paralysis. (3) Tubercle in the wall of the heart.

Mr. Lane. (1) Tumour of the bladder. (2) Partial mollities.

Dr. Hale White. Left inferior vena cava.

Mr. J. Poland. Suppurative arthritis of infants.

Mr. R. W. Parker. Lymphomatous glands removed from the axilla (recent).

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Thursday, May 8th, 1884.

Jonathan Hutchinson, Esq., F.R.S., President, in the Chair.

After announcing the Agenda for that evening the President called the attention of the members to the very handsome bookcase which had been provided by Sir Wm. Bowman, and hoped that it would be borne in mind by the members that it was their duty in return for such generosity to fill it. He also announced that the Council had decided to hold an extra meeting, and for the benefit of those coming from the country it would take place on the day before the Annual General Meeting, *i.e.*, Thursday, July 3rd. By permission of the Medical Society it was fixed for four o'clock in the afternoon, and it was arranged that only papers should be read and that there should be no exhibition of patients.

Mr. Nettleship showed an ophthalmoscopic drawing of a case of central guttate choroiditis (Tay's disease). The disease was considerable and symmetrical, but the sight was good notwithstanding. The patient was prematurely presbyopic. He also showed a drawing in which there were a number of small dark pigmented parallel lines in the choroid, as if this had been puckered into folds. There might have been some œdema of the choroid, which subsiding had left the choroid flaccid.

Dr. Stephen Mackenzie had recently seen two cases after papillitis, in which a white streak appeared in each fundus, going towards the yellow spot.

Mr. Adams Frost showed some eyes mounted in glycerine jelly, after Mr. Priestley Smith's method. (1) Ossification of the choroid and total detachment of the retina. Vision destroyed by a kick from a horse 30 years before enucleation. There had been several attacks of sympathetic inflammation. (2) Detachment of retina, with organised blood clot. (3) Detachment of retina and choroid by blood. (4) Detachment of retina, globe filled with laminated blood clot.

Mr. Jennings Milles exhibited microscopical sections from a case of ciliary staphyloma and irido-cyclitis, the case having on a previous occasion been reported to the Society by Mr. Adams Frost. He also exhibited a case of nævus of the right temporal and orbital region, with nævus of the choroid in the right eye and detachment of the retina on the same side. The boy was fifteen years of age, and had had a subcutaneous nævus of the right side of his face since birth. There had been no discolouration of the skin, and it varied in size. At the age of six years he was noticed to be blind with the right eye, but it was impossible to find out how long he had been so. The retina was completely detached, and close against the lens, there was bare perception of light. The left eye was myopic, and as there was some irritation, the right was excised. There was found a nævus of the choroid at the outer part, it was a cavernous angioma. He did not know of any similar recorded case.

Dr. Stephen Mackenzie referred to a paper by Dr. Allen Sturge in the "Clinical Society's Transactions," on a somewhat similar case, in which the occurrence of epileptiform convulsions had led to the supposition that there might be similar state of the meninges to that which was present in the skin. Dr. Horrocks had recorded a case of nævus of the retina during the last session.

Dr. Brailey said that there was a detachment of the retina, and a new fibrous layer in the choroid with at one spot the formation of a small bony structure in the choroid.

Mr. Nettleship said that in Dr. Sturge's case the condition was somewhat different, the eye was myopic, the choroid was darker than in the other eye, and perhaps thicker.

The President inquired if there had been, in either of these cases, any nævus of the cellular tissue of the orbit, to which both Mr. Milles and Mr. Nettleship replied in the negative.

Mr. Lang showed a case of new vessels on a fibrous growth in the vitreous in a chronic glaucomatous eye.

Mr. Morton showed a drawing of the same specimen.

Mr. Milles showed a microscopical specimen of a similar condition.

Acute Spasm of Accommodation.

Dr. C. E. Fitzgerald reported two cases of sudden accession of apparent myopia, which relaxed on instillation of atropine, but in the first case returned on the discontinuance of the drug. Spasm of the accommodation, to a greater or less extent, was, he considered, always present in young persons who were hypermetropic or myopic; but this acute spasm was, in his opinion, very rare. Donders stated that he had never seen a clear case of it; but he quoted three cases, two of them recorded by von Gräfe, and one by Leibreich. In 1879, a case had been published in the *Italian Archives of Ophthalmology*, by Professor Ravi. These were the only ones Dr. Fitzgerald was acquainted with, and the only work he knew which dealt fully with the matter was Professor Nagel's monograph on *Anomalies of Refraction and Accommodation*, published in 1866.

Mr. Adams Frost asked whether there was anything unusual in the occupation of the patient necessitating the use of his eyes much for near vision, and also what the age of the patient was.

Dr. Fitzgerald replied that the patient was a clerk, aged 23.

Nervous Disease with Ocular Symptoms, and Alleged Uniocular Diplopia.

Dr. James Anderson read an account for Mr. Marcus Gunn and himself, of a case of nerve-disease with ocular symptoms, including alleged uniocular diplopia. The patient, a painter, aged 34, came to the Moorfields Eye Hospital on October 20th, 1883, complaining of seeing several images of an object, especially when he looked to his left. He had convergent strabismus from partial paralysis of the left external rectus, with the usual homonymous diplopia arising therefrom; but, in addition, he asserted that with the right eye shut he still saw things double to the left of him. Except the paralysis of the left external rectus there was no abnormality in the muscular or refractive apparatus of either eye. The two images seen with the left eye were quite distinct, the right clear, the left dim, as were the images in the binocular diplopia, but nearer together than these. By the use of a prism, it was sought to separate the images given by the two eyes, and so to ascertain if he saw three images with the two eyes, but he never did so. The patient, a fairly intelligent man, answered with the manner of perfect *bona-fides*, and, so far as could be discovered, had no interest whatever in deceiving. In addition to the above ocular symptoms there was also atrophy of the left quadriceps extensor cruris, with loss of the left knee-jerk, the right being prompt and vigorous, also slight atrophy of the right scapular muscles and right thenar eminence, symptoms present in 1882, when he was under treatment in the London Hospital. When he applied at Moorfields, there was also very great loss of sensa-

tion, both common and special, in all areas supplied by the left trigeminus, as well as atrophy of the muscles supplied by its motor branch. There was no atrophy of the interosseous muscles of either hand, and none of the usual symptoms of lead-poisoning. The multiformity of the lesions, the affection of the trigeminus, and an obscure history of venereal disease, justified diagnosis of syphilitic nervous disease, and under iodide of potassium the abducens paralysis gradually disappeared. With this also disappeared the diplopia, both binocular and uniocular. The patient had recently, since giving up treatment, had several "fits" of doubtful character, in which he lost consciousness. After referring to the three cases already recorded in the Society's "Transactions" for 1882 (pp. 201, *et seq.*), and the subjective and therefore difficult nature of the symptom, Dr. Anderson, considering that there were too few cases for generalisation, simply emphasised, first, the occurrence of abducens paralysis with dilated pupil as a concomitant of uniocular diplopia, the two disappearing together in two of the four cases; and second, the presence of coarse cerebral disease in the two cases where there had been a *post-mortem* examination with the occurrence in the other two of symptoms consistent with, although not decisive of, coarse cerebral disease.

Dr. BRAILEY mentioned the case of a woman whom he had lately seen, who had some ataxic symptoms and uniocular diplopia: the patient had had syphilis. He had not been inclined to believe the patient's statements, but after the paper which had just been read he would investigate the case more carefully.

Mr. NETTLESHIP had recently seen another case—that of a young man with brain disease. He had paresis of the right external rectus, with ordinary diplopia, and diplopia of the right eye alone, chiefly to the extreme right of the field, a point which was also noted in Dr. Anderson's patient. An increase in size of the pupil on the paralysed side in sixth-nerve paralysis was common.

Dr. FITZGERALD had seen two cases of uniocular diplopia in which there was no paralysis of ocular muscles. One was a young lady with hypermetropia and asthenopia, who had marked uniocular diplopia with the left eye after reading; the other was a boy who was also hypermetropic. He mentioned also the case told him by a friend, of a gentleman who had always had uniocular diplopia, without anything to account for it being discoverable.

Dr. BRAILEY said that Mr. Snell was going to bring forward a case at a future meeting.

Mr. JULER had seen a woman, aged 40, who had paralysis of the left external rectus and diplopia with that eye alone.

Tortuosity of Retinal Veins in Association with Hypermetropia.

Dr. STEPHEN MACKENZIE showed a drawing, and read the notes of a case of great tortuosity of the retinal veins in the left eye of a patient of Mr. Streatfeild's, who was affected with hypermetropic astigmatism. The condition was practically confined to the one eye, which was the most hypermetropic. He stated that in the case of the girl he had exhibited last December, there was hypermetropic astigmatism, which was the greatest on the side where the retinal vessels were most tortuous. He had also a case now under care, a girl suffering from anæmia, whose retinal veins were tortuous, and there was slight hypermetropia. He alluded to other cases recorded, and showed that in most of the cases, great tortuosity had been associated with hypermetropia; and in some the tortuosity had been greatest in the most hypermetropic eye, yet in others the tortuosity had been equal in the two eyes when the hypermetropia had predominated in one; and similar tortuosity had been present in one patient who was emmetropic. He also alluded to the association of headache with the tortuous retinal vessels in some cases. He thought further facts bearing on the question were needed.

The PRESIDENT thought that the records of other similar cases would be peculiarly interesting.

Dr. BRAILEY mentioned a case of extreme tortuosity of vessels he had seen in a hypermetropic person, but the internal recti had been divided. In reply to Dr. Mackenzie, he explained that he did not attribute the tortuosity to the operation of dividing the recti, but there might have been some orbital cellulitis.

Extraction of Cataract.

Mr. HIGGENS read a paper summarising the results of his practice, accompanied by a table, in which were recorded the sex and age of the patient; the eye operated on; the form of cataract; the operation performed; the result; and remarks, when necessary. The number of operations was 200, and they were performed on 175 patients; 93 males and 82 females. 181 of the cataracts were nuclear; 19 were cortical. The results of the 200 operations were: 175 (87·5 per cent.) successful; 9 (4·5 per cent.) partially successful; and 16 (8 per cent.) failures. Extraction by a small flap-section, the incision being situated in the sclero-corneal junction, associated with iridectomy, was advocated. Anæsthetics were almost always employed, 12 operations only having been performed without. Reference was made to a paper printed in the seventy-second volume of the "Royal Medical and Chirurgical Society's Transactions," in which the details of 150 operations were given.

Hæmorrhage in Yellow Spot Region.

Mr. A. STANFORD MORTON read notes of a case of hæmorrhage in the region of the right macula, occurring in a patient aged 35, under Mr. Tay's care. The hæmorrhage was semicircular, but there were disturbances over a perfectly circular area extending from the optic disc to beyond the macula lutea. The patient's vision when first tested was only J. 20, but on March 31st was J. 1 and $\frac{20}{10}$. There was no history of blow or any illness, except that the patient was liable to attacks of rheumatic gout (probably true gout). The urine and heart were normal. The patient stated that, for the last two years, he had been subject to bleeding from the right nostril once or twice a week, but that this had ceased from the time his sight became defective until two days previous to his vision being found normal, a period of about three months.

The PRESIDENT noticed that the patient was said to have had rheumatic gout; it seemed to him that it was a typical case of true gout. [Mr. Morton here pointed out that the diagnosis of rheumatic gout was the patient's own.] It was an interesting case of hæmorrhage in an unusual place. He had seen several cases like it, but in none was the hæmorrhage of this shape.

Mr. NETTLESHIP thought that the half-moon shape was perhaps due to some anatomical peculiarity of the retina.

Mr. ADAMS FROST suggested that the hæmorrhage had been originally circular.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, MAY 1ST, 1884.

THOMAS BUZZARD, M.D., in the Chair.

CLINICAL EVENING.

BEFORE the business for the evening was proceeded with, a vote of condolence with the President, Mr. George P. Field, and with Mrs. Field, senior, was proposed by Mr. Malcolm Morris, and passed unanimously. Mr. O. A. Field, whose decease had taken place since the previous meeting, was at that time the Society's oldest member.

Case of Epileptiform Convulsions, with unusually slow pulse.

Mr. St. George Mivart read the notes of this case:—The patient was a retired policeman, aged 61, without any history of syphilis or acute rheumatism. There was no albumen or sugar in the urine. The first convulsive seizure took place six years ago; since then the patient had had five other fits, which all occurred in the stooping posture. The last fit occurred eight weeks ago; on the following day the patient was found to have a pulse of only 20 per minute; the pulse was firm and full between the beats. There was a slight systolic mitral murmur, together with an aortic systolic murmur. No hypertrophy apparently existed, since the impulse was diminished. Mr. Mivart considered the case to be one of fatty heart, with atheromatous deposit about the valves. He thought also there might be some slight aortic stenosis, giving rise to anæmia of the brain. He referred to the connection between attacks of syncope and those of minor epilepsy, and quoted the opinion of Dr. Russell-Reynolds to that effect. In this case he considered the seizures to be essentially of a syncopal character, modified by the epileptic tendency of the patient. Though much improved in other ways, the patient at the end of eleven weeks still presented a pulse as low as 24 per minute.

Dr. Hare related at some length a closely analogous case of unusually slow pulse, associated with *petit-mal*. The pulse had gradually dropped to the unparalleled rate of 13½ per minute, at which it was maintained for a considerable period, ultimately rising to 30 and 40. The patient, a nobleman, aged 57, had, up to the time of his illness, displayed the greatest activity, both mental and physical. Death occurred in a fit. No abnormality of the heart-sounds had been observed during life, and at the *post-mortem* examination the valves were found competent, and the heart but slightly enlarged and not markedly fatty. With the exception of slight enlargement of the kidneys, the other organs were practically normal.

Hypertrophy of bone due to Congenital Syphilis.

Mr. St. G. Mivart exhibited a lad, aged 18, in whom the left tibia was greatly thickened and curved anteriorly, as a result of congenital syphilis. Mr. Pepper gave the full details of a similar case (aged 22), where both tibiæ were affected even to a greater extent. The diagnosis of congenital syphilis was based upon the recent occurrence in the patient of interstitial keratitis, and upon the condition of the mother who was at the same time under treatment for periosteal nodes. Mr. Juler raised the question of treatment which was also discussed by Mr. Pepper and Dr. Buzzard.

Struma, Syphilis and Cancer in the same Patient.

This case was narrated by Mr. Pepper. The patient, a woman, aged 36, had suffered from scrofulous keratitis 30 years ago, presented scars on both her legs, and had suffered amputation of the breast in September last. A short time ago she had an epileptiform seizure and, within a few days, paralysis of the right facial, auditory and sixth nerves. The author was of opinion that the intracranial affection was probably syphilitic, although mercury had rapidly produced salivation. Dr. Buzzard, in commenting on the case, suggested that the cerebral symptoms might very probably have been due to the deposition of cancer within the skull.

Pathological specimens were exhibited by Dr. A. G. Silcock:—

(1) *Dilated Bronchi in a Child.*—The dilatation was uniform, tubular, and occurred at the right base, which was adherent to the pleura, and much condensed. Dr. Silcock had made the interesting observation that the right bronchus was pressed upon by some enlarged lymphatic glands, and he attributed to this cause the occurrence of the dilatation. Dr. Ewart agreed with the view which had been given of the pathology of this case. He was familiar with a form of bronchiectasis which was due to pressure upon some part of the bronchial tree, and he alluded to specimens from the *post-mortem* room of the Brompton Hospital, in which he had demonstrated the condition in question. He also called attention to the influence of the pleural adhesions, and of the chronic interstitial pneumonia, due to retained secretion, which favoured the bronchial dilatation.

Dr. Hare enquired whether there was in this case any evidence of chronic pneumonia, consolidation being often due, as in cases of whooping-cough, to pulmonary collapse.

(2) *Cancer of Uterus, with unusual Diffusion of Secondary Growths.*—The clinical history of the patient, from whom the specimen was derived, excited considerable interest and discussion. When admitted, her symptoms and her aspect bore such a resemblance to those of diabetic patients, that diabetes was at first sight diagnosed by two independent observers. No sugar, however, could be detected in the urine.

(3) *Sub-Peritonæal Sarcoma.*—The chief interest of this specimen lay in the widespread growth, and in the great rapidity of the extension of the disease. The case was at one stage supposed to be one of ovarian disease, and ovariotomy was for a time contemplated.

INTERNATIONAL HEALTH EXHIBITION.

Article III.

Vegetarianism.

There are two kinds of vegetarianism—one an extreme form, the members of which eat no animal food whatever; and a less extreme sect who do not object to eggs, milk, or fish.

The Vegetarian Society, now exhibiting at the International Health Exhibition, belongs to the latter more moderate division. From a communication forwarded to us by Mr. W. Harrison, we gather that the Society was founded at Ramsgate in 1847, and that since that date it has considerably increased in numbers. The activity of its leading members rivals that of the followers of the banners of Booth; they have held May Meetings in London, Leicester, Birmingham, Cambridge, Manchester, and elsewhere; they have distributed gratis any number of pamphlets and essays; they support at least one journal, and under their encouragement vegetarian dining rooms have been opened in many of the large English and Scotch cities.

At the Exhibition they have a pleasant airy room, ornamented with paintings lent by friends or members of the Society: four æolus spray ventilators keep the air beautifully cool and fresh; the tablecloths and general feeding implements are clean and neat, and the attendance is ample and satisfactory. Since the opening of the Exhibition they have given a sixpenny dinner to some four or five hundred people daily, and we understand that hitherto expenses have been met. It must, however, be quite understood that the undertaking has no commercial basis, for any surplus is to be devoted to charitable purposes.

Practical vegetarianism has so seldom been studied in any impartial or scientific manner, that we have taken advantage of the exhibit to enquire into the matter somewhat closely—have partaken of a sixpenny dinner, and have had during two days every substance forming part of the dinner weighed; thus on Wednesday and Thursday the sixpenny bill of fare was:—

(1) Lentil or rice soup.
(2) Potato pie or haricot maitre d'hotel.
(3) Macaroni, or sago pudding, or stewed peaches with rice or porridge.

On Thursday there were 440 partakers of the sixpenny dinner, and the cook kept a careful account of the substances used in this bill of fare, which we have reduced into "*food equivalents*" as follows:—

	Ozs.
Albumenoids	280·2
Fat	196·5
Carbo-hydrates	1397·1
Mineral matters..	39·6

so that, presuming that the above amounts were equally

divided among the 440 consumers, each one would receive the following :—

	Ozs.
Albumenoids	·63
Fat	·44
Carbo-hydrates	3·17
Mineral matters..	·09
	4·33

The researches of a great number of physiologists and chemists have laid down the true principles of diet in relation to physical work, and the standard diet for ordinary labour is pretty much as follows :—

	Ozs.
Albumenoids	4·2
Fat	1·6
Carbo-hydrates	13·7
Mineral matters	1·0

It follows then, that it would require about six of the sixpenny dinners to support a man during a day's hard labour. Possibly the quiet sedentary work of a clerk could be supported on three such meals. Speaking personally, the writer felt after eating the above, that he had a very pleasant, well-cooked digestible meal, but only of the character of a light lunch. The cost of the materials used for the 440 people at ordinary prices, works out at a little over 2*d*. a-head; the Society, of course, buy at wholesale prices, so that probably the prime cost will be a little under 2*d*. We believe that so far as price goes, the sixpenny meal would compare favourably with ordinary restaurant meals, the usual cost to the customer being much more than three times the value of the raw material. We must, however, in justice to the Society, add that the bill of fare criticised is one of their lighter kinds; and that on certain days of the week, a more substantial *menu* is substituted.

The National School of Cookery.

The National School of Cookery is under the superintendence of Mrs. Charles Clarke; it has been in existence since 1874, and has done much useful work, its objects being—(1) To train and qualify persons to become Teachers of Cookery in Training Schools, School Board Schools, Poor Schools, and similar institutions. (2) To teach Cooking to any person desirous to learn. (3) To send Teachers of Cooking, with the necessary armamenta, to any part of London or the Provinces.

The number of people who have been taught Cooking during the past ten years at the School amounts to 22,612, which is a large enough figure to justify its establishment. The National School of Cookery have dining-rooms at the Exhibition, in which may be bought shilling dinners, and on certain days sixpenny dinners. As far as possible the *menu* is so arranged as to follow a little work, written by Mrs. Clarke and published by the Executive Council, entitled, "Receipts for Cheap Dinners;" the consumer, should he care to purchase the little book, has therefore the satisfaction of knowing what everything is composed of, and how it is made.

So far as our personal experiment goes, we regret to say that the cooking of the viands did not seem to us quite perfect, the cleanliness of the table and appliances not absolute, and the difficulty in getting a suitable supply of malt liquor was exasperating. But we hope that these little defects, which are certainly marring the popularity of the School, are due simply to the sudden stress of a new departure, and will as time goes on be remedied.

The Dairies.

The opinion is gaining ground that "milk," almost as much a necessity of civilised life as "water," should only be supplied to urban populations by large proprietors or companies, for they alone have the requisite capital to construct their dairies and cowsheds on proper sanitary principles, and they alone have the capital to house their workmen, and to regulate the farms from which their supply is derived. No small amount of the milk-supply of the poor in London is retailed from little general shops, the rest of the house being let out in tenements, and possessing neither a safe, clean, nor cool storage place.

We see in the exhibits of three large dairies the most modern mechanical appliances for the cooling of milk, for the separation of cream, and for the making of butter.

The London and Provincial Dairy Company have a very complete exhibit of all that is necessary for the successful working of a large milk business.

The Express Company show a model of their farm at Crouch End, Finchley, which they have had constructed on the latest sanitary principles. They show also Guernsey cows, a German cream separator, the material being phosphor bronze, and besides the ordinary milk produce, they show goats' milk from a goat farm of theirs at Dorking.

Messrs. Welford have erected a bright attractive model dairy, and, taking all things into consideration, their exhibit is perhaps the best. They show a model of the excellent drainage carried out at their establishment in Elgin Road, which, it will be remembered, was erected at considerable outlay some little time ago; some fine Alderney cows, Laval's separator at work, dividing the cream from the milk, churns, and various other appliances. Messrs. Welford have issued a printed circular lately to all farmers supplying them with milk, the effect of which will be that, instead of it being to the farmer's interest to conceal any infectious disease, whether in man or animal, on his farm, it will rather be to his interest to communicate the fact to Messrs. Welford. Such a spirited measure as this cannot fail to give the Warwick Dairy proprietors a fair amount of protection, and also to increase the confidence of their customers.

Messrs. Bradford & Co. show a small compact dairy, in which there are special appliances for keeping the air cool and free from dust. At the time of our visit, an exceptionally warm day, we found the temperature below 58°.

In concluding this article we must not omit the exhibit of the Pure Standard Food Company, which, though less pretentious than the rest, is not without interest.

OBITUARY.

ADOLPHE WURTZ.

From among the numerous tributes to the memory of this distinguished chemist which have appeared in the French Medical Press, we select the following, which M. Gilles de la Tourette has contributed to the *Progrès Médical*:—

"A few days only have elapsed since, at the grave of J. B. Dumas, one of his pupils, himself long since 'past master' in his science, recalled in eloquent terms the scientific life of the man who had been his teacher and his friend. The savants who were present at the obsequies of the great chemist, little thought that one of their number would so soon be called upon to pronounce a funeral address upon him who then spoke in their names. If there was ever a fruitful career, it was surely that of Adolphe Wurtz, who, endowed with an unequalled activity and ardour, never put off anything until the morrow, and was surprised by death in the very midst of his labours. Born at Strasburg, in 1817, he received the diploma of doctor from the Faculty of Medicine of that city, in 1843, and from the very outset of his studies showed an irresistible vocation for chemistry, and especially for that chemistry of the organic compounds, which he was so to enrich by his discoveries. He became the friend and fervent disciple of Charles Gerhardt, an Alsatian like himself, who founded the atomic theory of chemistry, but, prematurely snatched from science in his 35th year, left its development to be carried out by his pupil, in whose hands it acquired so considerable a reputation. But the eager activity of the young chemist demanded a wider field than Strasburg could supply, and repairing to Paris, he quickly obtained in the Faculty of the French capital the same post which he had held in that of Strasburg. Three years later, in 1847, he was appointed an *agrégé* in the Faculty of Medicine. The judges made at this *concours* a happy selection for the accessory sciences, by nominating on the same occasion Adolphe Wurtz, Jules Regnauld, and Charles Robin. Henceforth, the new *agrégé*, who shortly attained the rank of professor, on the resignation of J. B. Dumas (1852), led organic chemistry

into paths which none as yet had ventured to penetrate, labouring at it incessantly, and endowing it with new possibilities. In 1849, he announced to the world the discovery of the ammoniacal compounds. The constitution of the organic alkaloids, which we daily employ in medicine, and which plants are incessantly producing, was no longer a secret, now that his scientific researches had shown us how to reproduce them in the laboratory. His labours were pursued without pause. In 1856 he discovered the glycols, in 1859 the oxide of ethylene, and in 1876 he performed the synthesis of neurine. . . . . All these discoveries Wurtz expounded, in a most philosophical manner, in works which quickly acquired a classic standing, such as "Leçons de Philosophie Chimique," "Traité de Chemie Médicale," "Traité de Chemie Moderne," "Histoire des Doctrines Chimiques," "Dictionnaire de Chemie" (in collaboration with the most distinguished chemists of our time), and many others. Biological chemistry and organic chemistry are but two branches of the same tree, and thus Wurtz, in 1859, was the first to discover that chyle and lymph are much richer in urea than the blood; and, quite recently, he exhibited the considerable power of soluble ferments, by proving that these ferments enter into unstable combination with fermentable matter (fibrin), a combination which water destroys in regenerating the ferment. In this way, one part of pepsin can digest 2,000 parts of fibrin.

"Wurtz having become the unquestioned leader of the chemical school in France, the laboratory which he had established at the Faculty of Medicine, was the centre of attraction for all those who felt drawn to this branch of science, and pupils assembled around the master from all parts of Europe. Wurtz had nothing of the jealous, morose *savant* about him. His pupils felt that in him they had a benevolent friend who, through the discussions which he started, illuminated them with the light of his brilliant genius—one who knew how to scatter all hesitations, to calm by a kind word the annoyances of tedious research, and to infuse courage into the heart of the dullest worker. Honours were not wanting to him. Already a member of the Academy of Medicine, he was elected into the Institute in 1867; while from the Royal Society of London he received the Faraday medal in 1878 and the highly prized Copley medal in 1881. But nothing can give more satisfaction to the *savant* than the opportunity of disseminating the ideas of which he has constituted himself the champion; and in 1875 Wurtz had a chair founded for him in the Faculté des Sciences. He was enabled henceforth, amidst his new surroundings, to make many proselytes, and his ardent language and true scientific eloquence decided many a career. Such was the esteem of his colleagues at the Academy of Medecine that, when, in 1865, Professor Tardieu resigned the office of dean, they decided to confer it upon Professor Wurtz. It was at a very turbulent period, when police agents contrived to bring about disturbances among the students; the pretext was seized upon to make arrests on a large scale. Not only did the new dean never allow the police to pass beyond the gates of the Ecole, but he was often instrumental in obtaining the liberation of students unjustly arrested. He resigned in 1875, having established laboratories at the Hotel Diéu, la Pitié, and la Charité, and obtained the reconstruction of the Ecole Pratique. In 1881 he was chosen senator for life by the Left Centre, and in 1882 was promoted to the rank of Grand Officer of the Legion of Honour. All these honours did not change the man. His affability seemed only to increase, and his life passed away, calm, tranquil, and patriarchal, in the midst of his pupils by whom he was so much cherished, and his numerous family. In his laboratory he reserved the place of honour for Professor Caillot, one of his old Strasburg teachers, who still survives him. Here they would compare their recollections of the old Faculty, and dwell upon their lost country; for Wurtz was an ardent patriot. Not content, in 1870, with transforming his house into an ambulance, he repaired himself to the fields of combat to succour the wounded. After the battle of Champigny the devotion which he had exhibited would have obtained for him a promotion in the Légion d'Honneur; but he declined this on the score that he had simply done his duty."

GENERAL CORRESPONDENCE.

ANTISEPTICS IN ABDOMINAL SURGERY.

[To the Editor of the Medical Times.]

SIR,—In a review published last Saturday, at page 672 of your present volume, you make some remarks which are strongly confirmed by the following extract from a lecture by Dr. John Homans, of Boston, published in the *Boston Medical and Surgical Journal*, April 10th, 1884:—

"In publishing the following lecture to students it may be proper for me to say that I have opened the abdomen for various purposes 203 times. I have done the operation of ovariotomy 159 times. My first five cases of ovariotomy were performed without any antiseptic precautions whatever and all died. In the next 100 cases I used antiseptic agencies, including spray. Of these, thirteen died and 87 recovered. Since then I have operated for ovariotomy 54 times with four deaths. My last thirty cases have all recovered. I ought, in this connection, to say that I have never declined to operate but once, the patient in that case having been already tapped to the amount of 2,270 pounds in five years. I have operated upon all the other cases that have come to me, and although my late continued success is doubtless owing to good fortune, I feel that I can now perhaps do the operation better than I could at first."

The precise antiseptic "precautions" or "agencies" used by Dr. Homans may be gathered from what he says as to the spray, sponges, and dressings:—

Spray.—"I always use the spray and need a steam atomizer. I do not believe that the spray is absolutely essential, but I have had very good success with it, and have never known that it has done any harm."

This is especially interesting when considered together with Sir Joseph Lister's own confession as to his doubts of the importance of the spray, with Billroth's belief in its inutility, and with the doubts expressed long ago by Sir Spencer Wells, whose own practice and example, however, are still in accordance with the statement of Dr. Homans. At page 220 of his last work, published in May, 1882—Ovarian and Uterine Tumours—Sir Spencer Wells says:—

"I feel still doubtful about the spray—'striving to better, oft we mar what's well.' In prolonged operations, I have had reason to fear that its chilling effect upon the patients has been injurious. But I have never once seen any other ill-effect which I could attribute to it, nor anything like carbolic poisoning. The misty cloud occasionally obscures the field of operation, but not to any serious extent; and it is always easy to protect the peritoneal cavity against the continued action of the spray by a large warm sponge. After a few trials I gave up thymol spray as useless, and for more than a year past have used a spray of absolute phenol, of a strength of one in forty. And this I continue to use, believing it to be safer than the irrigation or sponging proposed as substitutes, although I fully admit that we require a far greater number of trustworthy experiments, or of comparative observations made under similar conditions with and without spray than have yet been made known, before we can receive any satisfactory answer to the questions whether carbolized vapour or air can destroy, or render innocuous, infective or putrefactive substances or germs floating in the air; or what is the share which the spray, among other additional antiseptic precautions, has had in obtaining the better results which have undoubtedly accompanied their combined employment."

The other antiseptic precautions used by Dr. Homans are thus described in his lecture:—

Sponges.—"About 40 clean soft sponges of various sizes, which have been soaking for several weeks in a five per cent. solution of carbolic acid. I have three barrels filled with solutions of carbolic acid, and these barrels are kept full of sponges. Each barrel is used alternately. Some of my sponges have been soaking for ten years. I formerly

used sponges but once, but now I use them over and over after they have been cleaned.

On this detail Sir Spencer Wells says, at page 219 of his work from which I have just quoted:—

"After an operation I continue my old plan of keeping the cleansed sponges in a weak solution of sulphurous acid, and during the operation, in addition to washing in pure water, every sponge before use is wetted with a two to three per cent. solution of carbolic acid, or absolute phenol. Soft, clean linen cloths, wetted with a warm solution of phenol, may be used to lessen the number of sponges required; and nurses must be cautioned not to put any of the soiled sponges into the solution until after they have been washed, otherwise albumen may be so congelated as to prevent thorough cleansing. As nurses often fall into this error, it is well to have two or three different sets of sponges, all carefully numbered, kept separate for the successive steps of the operation."

Dr. Homans probably adopts these precautions with his nurses or assistants, though he does not mention them. The advantage of sulphurous acid over carbolic acid solution for keeping the sponges in, is that they remain soft and nearly white, while in carbolic acid they become harder, and assume a brownish red colour, suggestive of uncleanness. Dr. Homans also says:—

"I always wash my hands and forearms thoroughly, with a nail-brush in carbolized water, before beginning an operation, and require my assistants to do the same."

With regard to the dressing, he says, after having closed the wound by sutures:—

"I put on dry carbolized gauze, and enough new and clean cotton-wadding to fill up the hole left by the removal of the tumour. Next I pass a broad piece of adhesive plaster tightly round the abdomen over the dressings; this should be wide enough to extend from just above the trochanters to the sternum. Over this I pin a soft flannel swathe."

These are the only parts of his very interesting lecture which affect the question of antiseptics in ovariotomy. The whole of it, however, is well worthy of attentive consideration. In the meantime I may ask whether the "greater number of trustworthy experiments, or of comparative observations made under similar conditions with and without spray," said, in 1882, by Sir Spencer Wells, in the passage we have just quoted, to be required, have not been made in the hospital where he operated himself for so many years, and where he still acts as Consulting Surgeon. It is very well known by all visitors to that hospital that Dr. Bantock has altogether given up the spray, while it is always used by Mr. Thornton and Mr. Meredith. Surely some full and accurate account of such a remarkable series of "comparative observations made under similar conditions" might be drawn up, if not by the busy seniors, by some trustworthy junior. This would go far towards the settlement of a very important practical question.

I am, Sir, your constant reader,

A TEACHER-STUDENT.

London, May 19th, 1884.

THE COUNCIL OF THE COLLEGE OF SURGEONS AND REFORM.

[To the Editor of the Medical Times.]

SIR,—It is quite impossible that the controversy between the Council and the great body of the Fellows can remain where it is. As the mover of the resolutions which were carried at the late meeting, and which have been so ignominously ignored by the Council, I feel bound to take further action. I propose, therefore, at once to place myself in communication with the Fellows, in order that some united action may be decided upon.

I am, Sir, yours, &c.,

PAUL SWAIN, F.R.C.S.

THE EDINBURGH UNIVERSITY AND ITS TERCENTENARY.

[To the Editor of the Medical Times.]

SIR,—You, in common with other medical journals and the daily press, have recently written a great deal of "high falutin'" copy in connection with the University of Edinburgh. I wonder whether you will have the courage to publish a few lines as the reverse of Tercentenary Medal. Scotchmen are as weakly eager to be treated with indiscriminate praise as they are ungenerous in the proffering of indications of admiration or approval of others. It is no wonder that the tercentenary has been written up by Scotch contributors in every journal throughout the country, since, not only is the national vanity thus flattered, but a grand advertisement for a lucrative business is thus obtained. After all, what has the University of Edinburgh done during the last 25 years, except to sell degrees and a very minimum of instruction to those who choose to pay? The Professors of the University have made large incomes by lecturing to gigantic classes, attendance upon and payment for which are compulsory on those who desire a degree. What have these Professors taught? and what have they done besides selling degrees? They are, with scarcely an exception "just nobodies," men whose names are never mentioned beyond Edinburgh—men who, if they ever did make an original contribution to science, have ceased all such superfluous exertion since entering upon the professorial status. What have their pupils done? I do not hesitate to say, nothing of any consequence. And moreover, it is the fact that there are no graduates of any University in Britain so devoid of general education, so ill-trained in their special studies, as are the Edinburgh medical graduates. Far from deserving the lavish praise which it has lately received, the University of Edinburgh ought to be stopped in its scandalous career of mercenary degradation. Of the 3,000 students, only one-third are Scotch, and all go there, *not* because they can best learn at Edinburgh, but because there they can *buy most readily a degree*. The University allows the Professors to make a pretence of teaching 500 students in one class, and carries out this system of sham instruction in all departments, selling its degrees only to those who have attended these huge sham-classes. The whole proceeding is known both by students and professors to be humbug. The degree is bought by the one and sold by the other, but science and learning have nothing to do with it. It is as an advertisement in this highly creditable business of degree-selling that the Edinburgh Tercentenary has been organised. The so-called success of the University is the success of an advertising linendraper.

Yours, &c.,

ACADEMICUS.

[We publish this letter, not because our contributor dares us to it, but because there is a grain of truth in his allegations. Not more than a grain, however. "Academicus" must have forgotten that a considerable proportion of our younger physicians, and at least one of our most rising surgeons hail from Edinburgh, and that only within the last few years we have invited to London two Edinburgh Professors to take prominent and well-merited positions at the head of their respective branches of work. Another fact which "Academicus" ignores, or is ignorant of, is that only a small percentage of the students who study at Edinburgh University take University degrees. The rest take the licences of the Colleges. We grant that Edinburgh teachers are "canny," but they do not deserve all the abuse of "Academicus," who, if he does not take care, will be "hunted to death by wild Scotch graduates."

ED. *Medical Times.*]

THE UNIVERSITY OF DURHAM AND ITS MEDICAL DEGREES.

[To the Editor of the Medical Times.]

SIR,—The letters which have appeared in the *British Medical Journal* and other papers during the past few weeks, concerning the proposed change in the regulations for the degree of M.D. of the University of Durham, for

practitioners of fifteen years' standing, have created a very strong feeling among the graduates and undergraduates, which culminated in a crowded meeting held at the Infirmary on the 16th instant, Charles Green, M.D., Durham, Medical Officer of Health for Gateshead, in the chair, at which the following resolutions were unanimously passed :—

I. That this meeting hears with great dissatisfaction that there is in preparation a memorial praying the Senate of the University of Durham to alter existing regulations concerning the degree of M.D. for practitioners of fifteen years' standing.

II. That this meeting is of opinion that the proposed alterations would greatly detract from the value of the degree as obtained in the usual course.

III. That the degree of M.D. obtained by other than the usual course, viz. :—that of putting in residence, attendance on lectures and the passing of the several examinations—is prejudicial alike to the interests of the University of Durham and to the status of those who have obtained the degree in the orthodox manner.

IV. That a humble petition be prepared to present to the Senate praying it, not only to neglect the memorial suggesting the aforementioned alterations; but also very earnestly praying it to consider the advisability of abolishing the degree of M.D. for practitioners of fifteen years' standing.

V. That an account of the proceedings of this meeting, with the resolutions passed, be sent to the medical journals for publication.

A small committee was formed, of which Dr. Green was elected chairman, for the purpose of drawing up a petition in accordance with the above resolutions.

A circular letter is about to be sent to all graduates in medicine of the University of Durham other than those who have obtained the M.D. for practitioners of fifteen years' standing, whose addresses appear in this year's "Medical Directory."

We shall also be glad if those whose addresses do not appear will communicate with us *at once*, as we are anxious that no time shall be lost.

We are, Sir, Your obedient Servants,
J. A. HUTCHINSON, M.B., M.R.C.S.
C. POPE WALKER, M.R.C.S.,
Hon. Secretaries.

University of Durham College of Medicine,
Newcastle-on-Tyne, May 19th.

THE APOTHECARIES' SOCIETY.

[To the Editor of the Medical Times.]

SIR,—I am much obliged by your courtesy in inserting my letter in your last week's issue, though I cannot for one moment admit the force of your arguments for the exclusion of the Society of Apothecaries from all part in the medical education of the future. Indeed, your arguments would apply equally well to the case of the other Corporations, whose governing bodies and not licentiates will send representatives to the Medical Board; and, moreover, I am at a loss to conceive why age and experience should be a bar to the exercise of so important a function. You yourself admit that the Society of Apothecaries has done good work in the past, and has chosen good Examiners, Why, then, should they be incapable of choosing good representatives on the Medical Board?

I still firmly believe that if the Society of Apothecaries is excluded from representation on the Medical Boards of the future, that not only will a great injustice be done, but a great evil, as by this means the genuine general practitioner will be excluded from having a voice in medical education: for I am of the same opinion as the writer of the recent article in the *Times*, that the proposed representatives of the general practitioner on the Medical Council will consist of professional agitators who will be worse than useless.

In conclusion, allow me to say that I strongly deprecate the formation of another and lower order of medical men.

I remain, Sir, yours faithfully,
HENRY BULLOCK.

Spring Grove, Isleworth, 20th May, 1884.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners on the 17th instant, and when eligible will be admitted to the pass examination, viz. :—Messrs. H. D. Mason, N. D. Best, A. W. Thompson, and E. F. Pratt, students of the Birmingham School of Medicine; H. T. S. Aveline, of the Bristol School of Medicine; J. H. Lightbody, of the Liverpool School; E. R. Lyth-Arthur Green and E. J. Booth, of the Newcastle-upon-Tyne School; J. W. Stainforth and C. A. Ridal, of the Sheffield School; G. A. Webster, of the Cambridge School; and H. de C. Woodcock, of the Leeds School. Eleven candidates having failed to acquit themselves to the satisfaction of the Board of Examiners were referred to their Anatomical and Physiological studies for three months. The following gentlemen passed on the 19th instant, viz. :—Messrs. William Aston, A. D. Miller, F. A. P. E. Phillips, John Westwood, and J. M. Ehrhardt, of the Birmingham School; Shirley Roberts, of the Dublin School; J. G. Johnson and W. B. Slyman, of St. Bartholomew's Hospital; H. B. W. Paige, of the Newcastle School; Robert Dane, of the Middlesex Hospital; C. G. Jackson, of the Leeds School; W. J. Neale, of the Liverpool School; and G. W. Caswell, of University College Hospital. Ten candidates were referred for three months. The following gentlemen passed on the 20th instant, viz., Messrs. H. H. Norton and P. L. Nettleship, of St. Mary's Hospital; A. A. Howell, of the London Hospital; A. H. Johnston, M. E. A. Wallis, and G. M. Jones, of Guy's Hospital; Edward Knight, of University College Hospital; E. W. Morris, of St. Thomas's Hospital; C. P. Bullock, of St. Bartholomew's Hospital; and C. W. Edwards, of the Middlesex Hospital. Thirteen candidates were referred for three months, and one for six months. The following gentlemen passed on the 21st instant, viz. :—Messrs. J. F. Bridgwood, J. F. Rymer, Enoch Moss, J. L. Roberts, H. E. Vincent, students of Guy's Hospital; C. H. Dixon, of St. Mary's Hospital; C. J. Holtom and John Melhuish, of University College Hospital; C. H. Hands and A. D. Louttit, of St. Bartholomew's Hospital; J. H. Cox, of the London Hospital. Twelve candidates were referred for three months, and one for six months.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—This College, which two or three years ago established an examination and certificate in Sanitary Science, has, by a recent resolution, thrown open the competition for this important qualification to all registered medical practitioners of the United Kingdom. The examination is held quarterly, in the months of July, October, January, and April. The fee to Licentiates in Medicine of the College is fixed at five guineas; that to non-licentiates at ten guineas. The subjects of the examination are—(1) *Ætiology and Prevention of Disease* :—Epidemiology; Infection; Hereditary Influence; Accommodation and Conveyance of the Sick; Hospitals, and their Management. (2) *Engineering:* including Hospital and House construction; Sewage; Drainage; Ventilation; Water Supply. (3) *Law* :—The Acts relating to Public Health, Duties of Health Officers. (4) *Chemistry:* with special reference to Air, Water; and Food. (5) (A) *Meteorology and Climatology;* (B) *Vital Statistics.* The examinations will be conducted as follows :—A printed paper on each of the above five subjects, from 10 a.m. to 1 p.m., and 4 p.m. to 6 p.m. One hour to be allotted for the answering of each paper, which shall have five questions. The candidates will also be examined on a second day in the reading of Engineering Plans, Sections, and Scales, and in Analytical Chemistry, with special reference to Air, Water, and Food.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 15th, 1884 :—

Docker, Edward Scott, 2, Clarendon Villas, Barnes.
Frye, Joseph Henry, 66, Old Kent Road, S.E.

Gray, Jno. Power William, 24, Barnsbury Park, N.
Jones, Harry Shirley, Oak Hall, Bromsgrove.
Syrée, Anton Hugh, Canterbury.

The following gentlemen also, on the same day, passed their Primary Professional Examination :—

Kearney, James, Queen's College, Galway.
Wallington, William Tratman, Charing Cross Hospital.

NAVAL MEDICAL SERVICE.—The following appointments have been made :—Astley Cooper, Fleet-Surgeon, to the *Indus;* Thomas D'A. Bromlow, M.D., Staff-Surgeon, to the *Turquoise;* and John J. Dinnis, M.D., Surgeon, to the *Turquoise*. The Lords Commissioners of the Admiralty have awarded the Greenwich Hospital pension of 50*l*. a year for Fleet and Staff Surgeons to retired Deputy-Inspector-General of Hospitals and Fleets, David Lyall, M.D., rendered vacant by the death, on April 15 last, of retired Deputy-Inspector-General of Hospitals and Fleets, Henry Liddell.

ARMY MEDICAL DEPARTMENT.—Brigade-Surgeon C. M. Jessop has been placed on retired pay, with the honorary rank of Deputy-Surgeon-General; Brigade-Surgeon G. M. Slaughter, to be Deputy-Surgeon-General, *vice* J. Ekin, M.B., C.B., retired; Surgeon-Major H. Knaggs to be Brigade-Surgeon, *vice* G. M. Slaughter; Surgeon-Major H. H. Burford is placed on retired pay. Brigade-Surgeon N. Norris, now serving with the Army of Occupation in Egypt, has been appointed Sanitary Officer to the British troops at Cairo, *vice* Brigade-Surgeon Macdowell, who acted as principal medical officer to the late Soudan expeditionary force.

CAMBRIDGE UNIVERSITY. — In an appendix to the annual report of the Museums and Lecture Rooms Syndicate, Professor Macalister, the professor of anatomy, states that increased accommodation for his department is urgently needed, while Professor Foster and Mr. Sedgewick ask for additional accommodation for physiology and morphology as exceedingly pressing. The Syndicate hope to make a special report on this subject.

The following candidates have been examined and approved in Part I. of the third examination for M.B. degree.

Aldred, Caius; Bryceson, Christ's; R. T. Finch, Pembroke; Jones-Bateman, Caius; Mackenzie, Emmanuel; Milnes, Downing; Pash, Pembroke; Rutherford, Caius; Shaw, Sidney; Slater, John's; E. S. Whelpton, Emmanuel; White-Cooper, Trinity.

The following have passed the second part of the third examination for the degree of Bachelor of Medicine :—

G. A. Bolton, Trinity; Bryceson, Christ's; G. T. Clapp, Gonville and Caius; Cotes, Gonville and Caius; W. Groom, Magdalene; Hoffmeister, Gonville and Caius; Jones-Bateman, Gonville and Caius; M'Connel, Gonville and Caius; Manley, Emmanuel; Milnes, Downing; J. Scott, Gonville and Caius; P. C. Scott, St. John's; Shaw, Sidney Sussex; Warwick, non-collegiate; G. F. Welsford, Gonville and Caius; Wigmore, Magdalene.

The following have been examined and approved for degree of bachelor of surgery.

Dowson, Christ's; G. L. Johnson, Caius; Jones-Bateman, Caius; Pigeon, Christ's; and Roberts, Christ's.

UNIVERSITY OF DURHAM. EASTER TERM, 1884.

FIRST M.B. EXAMINATION.—The following candidates satisfied the Examiners :—

First class honours—None.

Second class honours, in order of merit—

Arthur Hardwick, Philip Percy Manning, Edward Samuel Gooddy.

Pass-list, in alphabetical order—

William Maurice Abbott Anderson, Frederick Bass, William Biggam, Arnold Francis Bradbury, Harry Edward Brodrick, John William Dalgliesh, Augustus Charles Dove, Alfred John Gregory, Francis Washington Everard Hare, M.R.C.S., Evan Lewis Hickey, John Lloyd Thomas Jones, William Lansdale, Edgar Roe Lyth, Arthur John Helm Montague, Charles Patrick O'Connor, Edward Phillips, Alfred G. C. Pocock, Henry Renney, James Nowell Richardson, M.R.C.S., William Frederick Steele, Edward Scott Sugden, Berners George Sumpter, Charles Pope Walker, A. Whyte.

Re-examination in Chemistry only—

Thomas Harling, Henry Beddoes Wetherall Plummer, Charles Frederic Rumboll, Edgar B. Sugden.

Re-examination in Botany only—

George Cranstoun, Henry W. Cross, Hugh Rayner, M.R.C.S.

The following passed in Anatomy, Physiology, and Chemistry—

William Joseph Essery, Richard Pryce Mitchell.

The following passed in Anatomy, Physiology, and Botany—

Harry Spelman Baumgartner, Charles Frederick Lyne Dixson.

Examination for Certificate of Proficiency in Sanitary Science—

Joseph Auspicio Simoens, M.D. Brus., L.M.S. Bombay, L.R.C.P. Lond.
Francis John Walker, M.R.C.S., L.R.C.P., L.S.A.

UNIVERSITY OF EDINBURGH.—The following candidates have passed the undernoted examinations held during last month :—*First Professional Examination.*—C. M. Allan, C. A. Anderson, D. H. Anderson, J. J. André, Alexander Asher, Benjamin Barnard, G. P. Beatton, Walter Bell, William Bell, W. W. O. Beveridge, H. L. Blacklaw, W. S. Bower, C. W. Brown, J. L. Brown, John Bruce, F. O. Buckland (B.A.), A. E. Bullock, M. B. Burton, Peter Cairns, James Cameron, L. B. Christian, J. M. Clarke, A. E. Cox, H. B. Densham (with distinction), Duncan Drummond, E. H. Ezard, A. D. Fleming, R. S. Forrest, S. C. Fowler, D. A. Fraser, W. M. Gabriel, T. H. Gee, F. S. Genney, J. A. Gibson, A. W. Gibson, A. L. Gillespie, George F. Grant, John Grant, Abernethy; S. E. Creg, Curt Grobbelaar, George Hall, George Hardyman, Charles Harvey, George Harwood, C. W. Hayward, G. S. Hicks, R. N. Highmoor, F. R. B. Hinde, F. A. Holmden, J. R. Holmes, Andrew Hostage, J. R. Hutton, Thomas Ireland, F. A. Juckes, William Kemp, H. R. Kenwood, Geo. Knowles, J. W. Lewis, W. J. Lewis, Frank Liddell, J. R. Lownds, John M'Andrew, John Macdonald, G. S. Macgregor, Henry Mackay, W. A. Mackintosh, D. M. Maclachlan, A. A. Macleod, H. W. G. Macleod, John M'Naughton, W. G. Macpherson, W. P. Magee, Alfred Mann, Alan Matheson, S. W. Mathias, T. G. Meikle, Thomas Meiring, A. van der Merwe, J. G. Moffatt, James Moir, H. M. Montgomery, T. L. Morgan, F. H. Morison, R. H. Morrison, P. R. Murison, M. F. X. Nalletamby, W. S. Nason, A. B. Northcote, G. J. L. O'Neill, William O'Rourke, J. C. Palmer, W. B. Paterson, S. C. Paton, H. N. Pelly, J. A. Perez, A. F. R. Platt, J. F. Pridie, G. M. Rae, C. Reid, Henry Robinson. A. R. Russell, J. S. R. Russell, G. S. Samuelson, H. C. L. Scofield, Walter Scott, L. Segol, W. A. Simpson, J. H. Slayter, H. M. Smellie, C. A. C. Smelt, Frederick Smith, Thomas Smith, W. C. Sprague, C. D. Stewart, Charles Stewart, James Taylor, W. R. Taylor, Alexander Thomson, Alexander Thomson, G. R. Thomson, T. H. Underhill, A. D. Vardon, A. H. Vassie, Thomas Walcot, E. D. Wellburn, P. J. White, George Wilson, O. R. M. Wood, and M. C. Wright. *Second Professional Examination.* — A. R. Aldridge, James Anderson, J. A. Ashcroft, J. M. Balfour (with distinction), H. L. Barker, T. W. Bell, R. N. Bell, Robert Beveridge, F. M. Blumer, G. L. Bonnar, L. J. H. Bouchet, Alex. Brewster, Harbit Brown, A. J. A. Campbell, Edward Chamberlayne, P. B. Chetti, E. W. Clarke (B. Sc.), F. G. Clemow (with distinction), F. W. Collinson (with distinction), J. F. Cownie, A. J. Cross, C. S. Davies, J. H. Dawe, Jules Delépine, K. M. Douglas (with distinction), D. R. Dow, Thomas Duncan, W. M. Eaton, Thomas Edwards, William Elder, T. L. Ferrier, L. G. Fischer, David Fraser, E. S. Fry (with distinction), Robert Fullerton, J. E. Gemmell, J. G. Glover, G. B. Goodall, Robert Gordon, T. H. Griffith, Benjamin Griffiths, Joseph Griffiths (with distinction), F. O. Guérin, G. L. Gulland, J. A. Guthrie, J. H. Helm, W. C. Helme, W. H. Hill, Herbert Hirst, W. E. Home, A. W. Hughes, Samuel Hughes, James Hunter, James Hutcheson, G. F. Johnston, T. J. Jones, R. C. Joyce, Arwid Kellgren, F. T. King (with distinction), F. H. Knaggs, Francis Kraemer, J. C. Lamont (with distinction), A. W. M. Leicester, L. H. Le Merle, W. M. Little, Duncan M'Diarmid, H. C. M'Ewen, J. M. Maclennan, R. C. Macwatt, D. G. Marshall, D. J. Mason, R. T. Meadows, C. H. Melville, William Miller, C. J. Morton, Edwin Morton, A. W. Nash, Glenmore Ozanne (with distinction), Alex. Paterson, Ian Paterson, M. G. Pereira, H. H. Pridie, E. E. Pringle, E. T. Pritchard, Ernest Roberton, G. M. Robertson, G. A. Scott, K. M. Scott, John Simpson, Thos. Slingsby-Tanner, G. R. Smeits, G. L. Somerville, W. C. Spiller, W. H. G. Stephen, Robert Stirling, R. C. Strode, James Stuart, W. G. Sym, J. R. Talbot, J. W. Talent, Caleb Terrey, W. E. Thomas, J. T. Thompson, Alfred Turner, J. C. S. Vaughan (with distinc-

tion), S. T. Vine, David Walker, D. H. Walsh, P. E. Warburton, John Warnock, F. E. Welby, W. J. Will, A. B. Winder, W. S. R. Woodforde, Henry Worsley.

University of Edinburgh.—The Vans Dunlop Scholarship in Physiology and Surgery has been awarded to Joseph E. Bowser.

Sir Spencer Wells.—Sir Spencer Wells has received the decoration of Commander of the Royal Norwegian Order of St. Olaf, forwarded by direction of His Majesty the King of Sweden and Norway.

Society for the Relief of Widows and Orphans of Medical Men.—The annual general meeting of the Society was held at 53, Berners Street, on Tuesday, 13th inst., at 5 p.m., Sir James Paget, Bart., President, in the chair. From the report (read and adopted) it appeared that the members of the Society numbered 370, no increase on the previous year; 11 new members had been elected during the year, 6 had died, and 5 resigned. Fifty-seven widows and 5 orphans were in receipt of grants, 3 widows less than in 1882. No fresh applications for assistance had been made during the year. A sum of 2,776*l.* had been distributed, and the expenses of the year amounted to 226*l.* The receipts available for payment of grants and expenses had been 3,160*l.* Two legacies had been paid, which with a life subscription of 30 guineas had been added to the funded property, making an increase of 311*l.* 10*s.* to the amount standing in the names of the trustees. Mr. James T. Ware and Sir Erasmus Wilson were elected Vice-Presidents, in the place of Sir James Paget, elected President on the retirement from office of Sir George Burrows, and Mr. Hawkins, resigned. Dr. Kempster, Mr. Felce, Mr. Brodhurst, Mr. B. T. Lowne, Dr. Herbert Davies, and Dr. Russell Reynolds were elected Directors in the place of the six senior who retired by rotation. A grant of 15*l.* was made under a special by-law to the daughter of a deceased member. The Chairman (Sir James Paget), in moving a vote of thanks to the editors of the medical journals, was pleased to have the opportunity of expressing how much the Society was indebted to the editors for the kindness and readiness they had always shown in forwarding and making known to the medical profession the great benefits the Society was able to confer on the widows and orphans of deceased members. Mr. Charles Hawkins moved a vote of thanks to the Chairman for his great kindness in taking the chair at the meeting.

The Small-pox Epidemic.—In consequence of the increase in the number of small-pox patients, the managers of the Metropolitan Asylum District have been compelled to remove all fever patients from their hospital at Fulham, and open the hospital only to those suffering from small-pox. The consent of the Local Government Board has had to be obtained to this arrangement.

Dr. Koch's Reports.—The reports of the German Cholera Commission have been published as part of a Parliamentary Paper on the Cholera Epidemic in Egypt.

Aberdeen Royal Infirmary. — From the annual report of this institution, just issued, we notice a large increase in out-patients, while the demand made on beds in the wards is still very great. Notwithstanding the special appeal to the general public, the financial year closes with a deficit of 659*l.* 19*s.* 2*d.* The much-required extension of the infirmary buildings, the managers regret, must be again deferred, as only one-third of the sum required for that object has been received.

The late Dr. David Manson.—Dr. David Manson, who died of inflammation of the lungs, at the early age of 45, on April 9th, at his residence, Eaglestone, Strathpeffer, was a distinguished graduate in Arts and Medicine of Aberdeen University. At the outset of his career he practised in London, but soon left, being chosen at the early age of 26 by the Duchess of Sutherland as resident physician to the Strathpeffer Spa. He remained at the Spa for a number of years, but gave it up for a more lucrative practice in Chesterfield. He was the author of two well-known works, "On the Strathpeffer Spa" and "On the Sulphur Waters of Strathpeffer," the last named passing through many editions, and helping to bring this once obscure Spa into notice.

Munificent Gift to Bellevue Hospital Medical College, New York.—Mr. Carnegie, one of the trustees of the school, has recently given the sum of 50,000 dollars to the College, to be expended in the erection of a building and apparatus for laboratories for practical work and teaching in everything relating to microscopical and experimental research in the different departments of medicine. The building will belong to the College, but the advantages pertaining thereto will not be restricted to students connected with the College. They will be open to students connected with other schools, and to members of the medical profession throughout the country.—*Philadelphia Medical News*, May 3rd.

Life Assurance on Negroes.—The *Boston Medical Journal*, May 1st, says: "The Senate of Massachusetts has passed a Bill requiring Life Insurance Companies within the State to remove the discrimination in tariff which they have hitherto maintained against negroes. It seems impossible that legislation of this sort can effect any good object. The former rules of the Companies were in no sense an oppression of the coloured race. If the rates were higher to them, it was because experience had shown that their expectation of life was not so good as that of whites, and all that remains now for the Companies is to decline to accept risks on negroes, which is no great gain to the latter. Such laws, if not mere political buncombe, are examples of legislation undertaking to fix the price of commodities, and are not likely to prove particularly successful."

New Disinfection Furnaces at Paris.—Mortuary depositories have been ordered to be erected in the Paris cemeteries, and these depots, of which there is one at Père la Chaise, are to be supplied with disinfecting apparatus, which will not only be employed in the case of death, but will be open to the public for the disinfection of the clothes and bedding of the sick. The Assistance Publique now possesses ten gas furnaces, three at the St. Louis, and one each at seven other hospitals. These establishments, together with ambulances for the conveyance of patients suffering from contagious diseases, the Parisian population owe to the exertions of several hygienists, as MM. Pasteur, Colin, Vallin, Vidal, &c. — *Gazette Hebdomadaire*, May 9th.

The Relative Calibre of the Trachea and Bronchi.—In a paper lately read before the Académie de Médicine, Dr. Marc Sée stated that he has deduced the following conclusions from his anatomical measurements:—"(1) In the normal state the united calibres of the two bronchi are equal to the calibre of the trachea, and I may add that, according to a few measurements which I have made, the united calibres of the bronchial subdivisions equal the calibre of the bronchus from which they originate. The respiratory passages therefore represent a cylinder and not a cone. (2) In the pathological condition, the equilibrium between the capacity of the trachea and bronchi may be destroyed, either in favour of the bronchi, as in chronic tuberculosis, or to the advantage of the trachea, as in emphysema."

Death of Prof. O'Keeffe.—Dr. Matthias O'Keeffe, the Professor of Materia Medica at Queen's College, Cork, and Lecturer in Medical Jurisprudence, has died at the early age of 54. Before his appointment as professor, Dr. O'Keeffe had been for several years librarian of the College. As a surgeon and physician he enjoyed a high reputation and a large practice. He acted as honorary surgeon of the local hospitals, and was an examiner of the Royal University. He was frequently employed by the Crown as analyst in important criminal prosecutions.

Samaritan Free Hospital.—A festival dinner, in support of the funds of this charity, was held at Willis's Rooms, on Tuesday, Lord Dalhousie in the chair.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The annual dinner was held at the Holborn Restaurant on Tuesday, and was largely attended.

THE Library of the Royal College of Surgeons will be closed, for the purposes of the examinations, on May 23rd and 29th

APPOINTMENTS.

BIGGS, C. E. F. M., M.R.C.S., L.R.C.P.—Junior House Surgeon and Cloroformist to the Cheltenham General Hospital and Dispensary.
CALDERWOOD, GEORGE, M.D., C.M.—Medical Officer to the Egremont District, Whitehaven Union.
DRUITT, LIONEL, M.R.C.S. Eng., L.R.C.P. Lond., C.M.M.D. Edin.—Medical Officer to the Seventh District, Lambeth Parish.
DUNCAN, W. A., M.D.—Assistant Obstetric Physician to the Middlesex Hospital.
ERSKINE, J., M.A., M.B., C.M., L.F.P.S.—Surgeon to the Ear Department of Anderson's College Dispensary, Glasgow, *vice* Thomas Barr, M.D., resigned.
GOSTLING, J. H., M.R.C.S., L.S.A.—House Surgeon to the Morpeth Dispensary, *vice* J. Erskine Paton, M.B., resigned.
GRAHAM, GEORGE H., L.R.C.P., M.R.C.S., L.S.A.—Medical Officer to the Workhouse and the Second District.
GREVES, E. H., M.B., M.C.—Physician to the Liverpool Infirmary for Children, *vice* F. Pollard, M.D., resigned.
JONES, ARTHUR, C.B., M.R.C.S. Eng.—Medical Officer to the Empingham District, Oakham Union.
LOTHIAN, J. A., M.D., F.F.P.S. Glasgow.—Surgeon to the Glasgow Royal Infirmary.
MCDONNELL, C., L.R.C.S.I., &c.—Surgeon to the Dawson Street Dispensary, Manchester.
NUNNERLEY, R. J., L.R.C.P., M.R.C.S.—Junior House Surgeon to the Macclesfield General Infirmary, *vice* R. W. Branthwaite, L.R.C.P., M.R.C.S., resigned.
PRUEN, S. T., M.B. Durh., M.R.C.S.—Senior House Surgeon to the Cheltenham General Hospital and Dispensary.
ROOCROFT, W. M., M.R.C.S., &c.—Reappointed Honorary Surgeon to the Royal Albert Edward Infirmary, Wigan.
SMITH, FREDERICK W., L.R.C.P., M.R.C.S., L.S.A.—Medical Officer to the St. George's Workhouse, St. Saviour's Union.
STEVENS, FRANCIS J., M.R.C.S., L.S.A.—Medical Officer to the Kilburn District, Thirsk Union.
STOKER, GEORGE, M.R.C.S.E.—Surgeon to the Hospital for Diseases of the Throat and Chest.
WOODHOUSE, STEWART, M.D.—Local Government Inspector for Ireland.
YOURELLE, Dr.—Medical Officer to Dunboyne Dispensary, County Meath, Ireland.

VACANCIES.

BIRMINGHAM GENERAL HOSPITAL.—Resident Assistant Surgical Officer. (*For particulars see Advertisement.*)
BOROUGH HOSPITAL, BIRKENHEAD.—Honorary Surgeon. Candidates must be Members of the College of Surgeons of London, Dublin, Edinburgh, or of the Faculty of Physicians and Surgeons of Glasgow. Applications to be made to the Honorary Secretary, W. W. St. George, Esq., 11, Holly Bank Road, Clifton Road, Birkenhead, on or before May 27th. The election will take place on May 29th.
DENBIGHSHIRE INFIRMARY, DENBIGH.—House Surgeon. Salary to commence at £85 per annum, with board, residence and washing. Candidates must be duly qualified. Conversant with the Welsh language. Applications to be sent to the Secretary, on or before June 5th.
DEPWADE UNION.—Medical Officer to the Seventh District, *vice* Mr. Heynes Hardwick, resigned. Area, 10,732 acres. Population, 2,703. Salary, £58 per annum.
FLINTSHIRE DISPENSARY.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free, &c. Candidates names must appear upon the Medical Register as being possessed of a medical and surgical qualification, and they must produce evidence of good moral character. Private practice strictly prohibited. Applications, with testimonials, to be sent to the Secretary, on or before June 11th. The election to take place on June 18th.
GAINSBOROUGH UNION.—Medical Officer for the Walkeringham District, *vice* Mr. T. B. Wright, deceased. Area, 15,732. Population, 3,835. Salary, £52 per annum.
GUEST HOSPITAL, DUDLEY.—Resident Medical Officer. Salary £120 per annum, with furnished residence, board, coal and gas. Candidates must be registered with a double qualification, and be unmarried. Applications, with testimonials, and certificates of registration, to be sent to Mr. E. Poole, Secretary, not later than June 4th.
HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE, W.—Resident Medical Officer. (*For particulars see Advertisement.*)
LOUTH UNION.—Medical Officer to the Withern District, *vice* Mr. James Hurley, resigned. Area, 18,123. Population, 2,678. Salary, £50 per annum.
NORTHAMPTON GENERAL INFIRMARY.—Surgeon. (*For particulars see Advertisement.*)
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiners in Medicine and Midwifery. (*For particulars see Advertisement.*)
ROYAL UNITED HOSPITAL, BATH.—Resident Medical Officer. (*For particulars see Advertisement.*)
STOURBRIDGE UNION.—Medical Officer to the Kingswinsford Third District, *vice* Mr. John Parrish, deceased. Population, 12,070. Salary, £54 per annum.
SUDBURY UNION.—Medical Officer to the Sixth District, *vice* Mr. C. W. Whistler, resigned. Area, 11,543. Population, 3,047. Salary, £59 per annum.
SUNDERLAND INFIRMARY.—Senior House Surgeon. Salary, £100 per annum, with board and residence. Candidates must possess double qualifications (registered). Applications, with testimonials, to be sent to the Chairman of the Medical Board, on or before June 2nd. The election will take place on June 12th.
THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, W.C.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)
TOWN OF CALCUTTA.—Health Officer. (*For particulars see Advertisement.*)
WOODBRIDGE UNION.—Medical Officer to the Third District, *vice* Mr. C. G. Marshall, resigned. Area, 14,187 acres. Population, 6,444. Salary, £110 per annum.

DEATHS.

ATKINSON, RICHARD, M.R.C.S., at Richmond, Yorkshire, on May 16th, aged 84.
GALE, HENRY STANLEY, M.R.C.S., at Manchester, on May 4th.
MURE, JOHN, M.D., Inspector-General of Hospitals (retired), at 40, Tedworth Square, on May 16th.
SMITH, FRANCIS KIRBY, F.R.C.S., of Northampton, at Ambleside, on May 11th, aged 37.
SPENCER, CHARLES, M.R.C.S., at Whitchurch, Bucks, on May 12th, in his 73rd year.

NOTES, QUERIES, AND REPLIES.

ACCIDENTAL SYPHILIS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I think Dr. Capers, of Vicksburg, Miss., can cap Dr. Thomas's wonderful case of accidental syphilis, described in your paper of May 17th, p. 667.

During one of the hard-fought battles between North and South a bullet passed through the testicle of a young and ardent soldier, and thence journeyed through the ovary and uterine wall of a beautiful girl of 17 who was aiding the wounded. Dxactly 278 days afterwards the lady was delivered of a fine healthy boy, in the testicle of whom was found the identical bullet that had wounded the mother. Dr. Capers thinks it possible some of his professional brethren may not be inclined to believe his tale true in all its details, but asks, Why not? A full and graphic account of the whole case is to be found in the *Lancet*, January, 1875, p. 35.

I am, Sir, &c.,
RICHARD NEALE, M.D. Lond.

May 16th, 1884.

Collegiate Lectures.—The annual course of lectures at the Royal College of Surgeons, which were suspended owing to the examinations for the membership, will be resumed on Wednesday, the 4th proximo, when Mr. E. A. Schäfer, F.R S., will commence his course of three lectures—the first on "The Functions of the Marginal Convolution;" second, on "The Analysis of Voluntary Muscular Action;" and the third on "The Mechanism of Absorption." The lectures will be brought to a close by Professor Sir Henry Thompson, F.R.C.S., who will commence his course of six lectures on Wednesday, the 11th proximo, on "Some Important Changes in connexion with the Surgery of the Urinary Organs. These several lectures will be delivered on Mondays, Wednesdays, and Fridays at 4 o'clock.

Collegiate Examinations.—The primary or Anatomical and Physiological examinations for the diploma of membership of the Royal College of Surgeons, were resumed on the 16th instant, when the following questions on Anatomy were submitted to the candidates, who were required to answer four, and not more, out of the six questions, between 1 and 3 o'clock p.m., viz.: 1. Describe the course and distribution of the cutaneous branches of the three divisions of the fifth cranial nerve on the face. 2. Describe the origin, course, and relations of the portal vein. Mention the situations in which it communicates with the systemic circulation. 3. Mention the structures in contact with the interosseous membranes of the fore-arm and leg. 4. Describe the mesentery; its attachments, length, structure, and the parts contained therein. 5. Describe the dissection required to expose the flexor longus pollicis in the fore-arm. 6. Trace from the commencement to the termination the various constituents of the spermatic cord.

The following were the questions on Physiology, to be answered between 4 and 6 o'clock p.m., viz.: 1. Describe the functions of the grey and white substances of the spinal cord. 2. Describe the structure of a Graafian follicle, and the maturation and discharge of an ovum. 3. What is meant by the partial pressure of a gas? What is the partial pressure of the oxygen in atmospheric air? How does expired differ from inspired air? 4. Give the innervation of the intrinsic and extrinsic muscles of the eye. State what would be the effect of the division of each of the nerves you mention. 5. Follow the successive stages of digestion which milk undergoes in the alimentary canal. 6. Describe the coloured corpuscles of the blood, and how they are affected by various reagents.

APPOINTMENTS FOR THE WEEK.

Friday, May 23 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Clinical Society of London.—Mr. Wm. Anderson, "A Case of Pyelo-lithotomy;" Dr. Finlay, "Sequel to a Case of Aortic Aneurysm;" Mr. Golding Bird, "Two Cases of Hernie en bissac;" Dr. F. Taylor, "A Case of Impaction of Bone in the Larynx;" Mr. B. Roth, "Uncommon Lateral Curvature of Spine, with extreme Osseous Deformity" (living specimen).

Royal Institution, 8 p.m.—Mr. D. Gill, "Distances of Fixed Stars," &c.

Saturday, May 24.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Royal Institution, 3 p.m.—Professor Bonney, "Microscopical Geology."

Monday, May 26.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, May 27.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Anthropological Institute of Great Britain and Ireland, 8 p.m.—Mr. Theodore Bent, "Notes on Remains from Cemeteries in the Island of Antiparos;" Mr. H. O. Forbes, "The Koeboes of Sumatra;" Mr. J. G. Garson, "On the Osteology of the Koeboes of Sumatra."

Royal Institution, 3 p.m.—Prof. Gamgee, "Nerve and Muscle."

Royal Medical and Chirurgical Society, 8.30 p.m.—Dr. G. E. Herman, "An Average or 'Composite' Temperature Chart of Small-pox;" Dr. G. W. Cayley and Mr. A. Pearce Gould, "Gangrene of the Lung treated by Drainage—Recovery;" Dr. Cecil Y. Biss, "On the Treatment of Pus-secreting Basic Cavities of the Lung by the Method of Paracentesis and Free Drainage."

Wednesday, May 28.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, May 29.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Royal Institution, 3 p.m.—Prof. Dewar, "Flame," &c.

Friday, May 30.

Royal Institution, 8 p.m.—M. E. Mascart, "Sur les Couleurs."

ON THE PATHOLOGICAL NATURE, ÆTIOLOGY, AND TREATMENT OF PNEUMONIA.[1]

By J. BURNEY YEO, M.D., F.R.C.P.,

Physician to King's College Hospital.

After a few introductory remarks Dr. Yeo said that no one would doubt that the keen and searching spirit of positive experimental inquiry which animated the pathology of our day was destined to greatly modify our conceptions as to the nature of disease, in many of its forms; bidding fair to make our present era one of the most remarkable and one of the most illustrious in the history of medicine. The mistaken attempt to base a rational pathology exclusively on morbid anatomy, upon the anatomical analysis of morbid changes, had been pushed, perhaps, to its extreme limits; yet pulmonary pathology must ever remain deeply indebted to these anatomical studies, and, in particular, for having enabled us to differentiate between many forms of pulmonary consolidation and infiltration, which we could not otherwise have accurately distinguished; but it was with the results of experimental inquiries in connection with pneumonia that they were now especially concerned. With the application of that method to the study of pneumonia we had entered upon a new phase in the pathological history of that malady, and it became necessary that we should ask ourselves whether the conceptions that had hitherto prevailed as to the nature of that disease were correct or erroneous. It was a subject of the widest and most general interest, and one which had, he thought, been wisely selected by the British Medical Association for the purpose of Collective Investigation, and by that important branch for immediate discussion.

The subject they proposed to examine was *acute lobar pneumonia*, the so-called croupous pneumonia of German authors, and he intended to limit his observations exclusively to its pathological nature, its ætiology, and its treatment.

It had recently been asserted that acute croupous pneumonia was a parasitic disease, and that it was caused by the entrance into the body of a peculiar and characteristic micro-organism. In order to establish the fact that a given disease was due to the presence of micro-organisms, it was held to be necessary:—(1) That an organism of definite form and characteristics should always be found in the blood, or in the diseased organs. (2) That the blood, or the diseased tissue, when introduced into another animal of the same species, should produce the same disease. (3) That when the blood or diseased tissue was inoculated on a suitable soil out-

[1] Abstract of an Address delivered at Birmingham before the Birmingham and Midland Counties Branch of the British Medical Association, on April 24th, 1884.

side the body, the micro-organisms contained therein should grow and be propagated indefinitely on similar soil. (4) That the organism thus separated from the remains of the material in which it was imbedded, thus isolated, when inoculated into a healthy animal, should reproduce the same disease, and the same organisms should reappear in the diseased parts. It was maintained that in pneumonia, as in anthrax, in septicæmia of the mouse, in erysipelas, in tuberculosis, and in glanders, all the conditions required to establish the fact that a given disease was due to the presence of a micro-organism had been fulfilled.

So long ago as 1875, Klebs asserted that pneumonia was a parasitic disease, and both he, and subsequently Eberth and Koch, had found a micro-organism in cases of pneumonia. But Friedlander had the credit of first accurately differentiating this organism, and describing its specific form and characteristics. He found these typical micrococci in the alveolar infiltration, amongst the leucocytes and red blood corpuscles, in eight cases of croupous pneumonia, which he examined after death. Günther found the characteristic organisms in some fluid he withdrew from the chest of a moribund patient, and Leyden found them in a few drops of blood withdrawn from the lung of a pneumonia patient, thirty-six hours before death.

These organisms, as described by Friedlander, were micrococci of elliptical form, one micro-millimetre in length, and one-third less in breadth. They occurred connected together in pairs, as *diplococci*, and frequently they formed longer chains; but these chains were distinctly seen to be made up of a series of pairs, a series of diplococci. They were characterised and differentiated from other micro-organisms found in the body by *being surrounded by a capsule*, which was thought by Friedlander to consist of mucin. The capsules, however, were not always present, and were not easily demonstrated. They were thought to be a product of the life of the micrococcus.

The *pure* organism obtained by Friedlander and others by cultivation, had been introduced into the bodies of animals, usually mixed with distilled water and injected into the pleural cavity. On 9 rabbits it produced no effect, but it proved fatal to 32 mice, in from 18 to 20 hours. The organism was found in enormous numbers in the engorged and hepatised lung, in the blood, in the spleen, and in the fluid of the pleura. In the latter situation the *diplococci* were encapsulated. When the same fluid was heated so as to destroy the organism, its injection produced no effect. Cultivations from these mice produced the same effect on other mice. An attempt was also made to introduce the organism into the lungs of mice by *inhalation;* the fluid containing the micrococci being diffused by a hand spray into their cage. In this experiment some mice were affected, some were not. In the case of the latter, it was suggested that but little of the fluid entered the lungs, as they turned their backs to the spray.

"But there is another consideration," said Dr. Yeo, "which has been somewhat overlooked in connection with the inhalation of pathogenic organisms, and to which I may take this opportunity of calling attention. It is, that under normal conditions the suspended solid particles in the atmosphere taken in with the *inspired* air, are cast out with the *expired* air. The mucus of the buccal and pharyngeal mucous membrane is crowded with micro-organisms, but these the ciliated epithelium of the air tubes keeps from reaching the air cells; and they, probably, penetrate but a short distance into the air passages with the *tidal* air. This was well-shown in a case of empyema communicating with the lung, which was under my own and Sir Joseph Lister's care, in King's College Hospital, last year. For though there was an opening in the lung, permitting the periodical ejection of large quantities of pus, the pus in the pleural cavity remained perfectly sweet and quite free from putrefactive organisms; which was no doubt due to this protective office of the bronchial ciliated epithelium. It has, no doubt, been a difficulty with many in the way of accepting the view that diseases like phthisis and pneumonia are dependent on the inhalation from the air of special pathogenic organisms, that so many escape infection who must, it would seem, occasionally inhale these bodies. But apart from the consideration that the causes of these diseases are complex, and cannot consist of a single factor, we must give due weight to the very obvious reflection I have just stated, viz.—that in the respiration of most healthy persons, whatever solid particles floating in the air, pass into the lung in inspiration, pass out of it in expiration; that the air ordinarily exchanged in respiration is the *tidal* air, not the air of the air cells, and that whatever organisms may penetrate beyond the limits of the tidal air, into the air passages, are arrested and driven back by the action of healthy bronchial ciliated epithelium. Now it is possible that one of the factors in the causation of these diseases may be, for instance, *a temporary or permanent paralysis of the ciliated epithelium*, or a denudation of this protection from a portion of the air passages. Or some abnormal condition of the mucous secretion may either, on the one hand, paralyse these cilia, or on the other, *stimulate these germs to overwhelming multiplication.* When we consider that the bacillus which causes septicæmia in the house-mouse is unable to produce any deleterious effect in the field-mouse, we must be struck with the very special nature of the conditions which determine the growth and activity of these organisms."

After dealing with the objections that had been made, especially by Parjesz, of Klausenberg, to Friedlander's view with regard to the organism he had named the pneumonia micrococcus, Dr. Yeo referred to the researches of Dr. Rudolf Emmerich, of Munich (*Fortschritte der Medecin*, March, 1884), who had proved that the material found stuffing the space between the floor and ceiling of the dormitories of a prison at Amberg, where epidemic pneumonia had long been, as it were, domiciled, was crowded with enormous masses of the peculiar organism which had been stated to be pathogenic of pneumonia.

These observations naturally lent great weight to a view of the pathological nature of certain forms of pneumonia, which was by no means new; for many writers in this and in other countries had expressed a suspicion that pneumonia sometimes occurred as an infective and contagious malady, and numerous instances of its epidemic occurrence were on record; while many, who would be unwilling to admit its infectious or contagious nature, were convinced of its occasional occurrence in what was called a "pythogenic" form. One of the most instructive instances on record of the supposed epidemic occurrence of pneumonia, and its supposed propagation by contagion, was described by Stokes, of Dublin, who wrote as follows:—"The occurrence of this disease, as affecting great numbers in a particular locality, was observed in this city some years since. The persons attacked were *young* and *healthy* men, privates in the constabulary force, who were quartered in the then newly erected barracks in the Phœnix Park; these young men were well fed and clothed, and might be considered as possessing the greatest strength and vigour. It is a remarkable circumstance that at the time of the appearance of this disease, many cases of another and extraordinary affection were observed in the poor-houses and hospitals in and near Dublin. I allude to cerebral-spinal arachnitis, and it is important to mention that several cases of this disease occurred in the force contem-

poraneously with those of pneumonia. The general characters of the pneumonia were suddenness of invasion and great rapidity of progress; the lung rapidly passing into hepatisation."[1]

Another interesting account of an epidemic of pneumonia was given by Surgeon-Major Costello, of the Bengal Medical Department. His regiment had lost from this disease between 30 and 40 men out of 550, in a few weeks. It was almost confined to two companies, and when it appeared amongst the married, it spread to different members of the family, and when cases were taken into hospital, it spread to other patients, ill of other diseases, and to the nurses and attendants. There was always a catching pain in the side, the infiltration spread rapidly through the lungs, and was attended with "typhoid" symptoms. Removal from barracks to tents, isolation of affected persons and their attendants, immediately arrested the progress of the disease.[1]

A very remarkable series of cases, pointing to direct contagion, had been recorded by Mr. Patchett, of Shaw, near Oldham,[1] and another, scarcely less remarkable, by Dr. F. H. Daly, of Hackney Downs.[1]

Many instances from the time of Courvoisier, Laënnec, and even earlier, were also on record of the epidemic occurrence of pneumonia; cases of pneumonia occurring together in groups, larger or smaller, and in which the suspicion of spread by contagion had not been altogether absent. These instances appeared to have occurred independently of any common meteorological conditions, but they had, in many cases, appeared to be in some way connected with local insanitary surroundings. A good example of the latter was the account given by Penkert[1] of an outbreak of croupous pneumonia in a village of 700 inhabitants, 42 of whom were attacked and 2 died, between the 11th of March and 14th of May, 1881.

They were doubtless aware that the question had been raised, whether these so-called epidemics of pneumonia might not be, in some instances, cases of typhoid, with early development of lung consolidation. It had also been observed that epidemics of pneumonia succeeded epidemics of typhoid, and epidemics of typhoid succeeded epidemics of pneumonia; and it would seem that the presence of putrescent matter was favourable to the culture of both germs.[1] In an epidemic observed by Kühn,[1] at Moringen, in Hanover, the approximation to typhoid in some of the cases was well marked. The cases occurred in an overcrowded prison; 33 cases were observed in one epidemic, and 70 in another. They differed from those of typical pneumonia—there was no initial rigor—and the onset was gradual; the intestinal follicles were sometimes found swollen, and diarrhœa was present in two-thirds of the cases. It was distinctly infectious, and spread to the attendants.

"I have here brought before you," Dr. Yeo continued, "but a small fragment of the mass of observations which are on record, and upon which was based the view that pneumonia is an infective disease dependent on the presence of a specific pathogenic organism in the body; and that under certain, somewhat rare circumstances of time, place, or season, it may spread by direct and indirect contagion.

"I have thought it best to bring this view of the nature of pneumonia before you, *first of all*, in order that we may the better be able to compare it with the older and more generally accepted views as to the nature of this disease, and see how it is related to them. Probably the most widely accepted view of the nature of pneumonia is that it is a typical local inflammation produced by exposure to cold, and that the accompanying pyrexia is merely symptomatic of the local lesion.

"Another view which, if not quite so widely accepted as the preceding, is certainly quite as authoritatively maintained, is that acute pneumonia is a *general disease*, and the lung inflammation is simply the chief local lesion. The inflammatory process in the lung is the *local* effect of a *general* cause. The usual arguments in support of the latter view are these:—That in well-marked cases the fever does not run parallel with the physical signs of pulmonary inflammation. It frequently precedes them by a considerable interval. It does not coincide with them in degree or duration. High fever often accompanies a small tract of inflammation when it is situated at the apex of a lung instead of at the base. The fever often suddenly subsides long before the local signs show a corresponding improvement in the lung. Moreover, it resembles the *specific fevers* in its typical course—the rapid onset, the sudden defervescence. Finally, the anatomical changes in the lung are not such as can be produced by artificial injury of that organ. . . .

"Of these two views, it will be seen that the one is entirely opposed to the theory which regards pneumonia as a parasitic disease, infective, sometimes contagious, and not infrequently epidemic; whereas the other view gains support from and is quite consistent with the belief in the parasitic nature of this disease. But there is yet another view which merits our attention, viz., that pneumonia is *sometimes* an inflammatory and purely local disease, and *at other times* an infective, general disease. This view has been advocated by Mr. Wynter Blyth.[1] After alluding to some interesting cases of apparent communication of pneumonia mentioned to him by Dr. Christian Budd, of North Tawton, he says, 'In all probability there are *two* forms of pneumonia—one probably arising from cold or a like cause, the other zymotic—and these two forms are at the present time confused together, just as typhus and typhoid were. That such an epidemic form exists, infectious, zymotic, self-propagating, I feel in my own mind convinced.'

"I must own there appears to me to be much that may be said in favour of this *eclectic* view. When we consider what diverse conditions are capable of setting up inflammation and consolidation of the lung, when we consider in what various morbid states secondary pneumonias occur, it is surely not inconsistent to believe that *primary* pneumonia may arise from more than one exciting cause. But even if we admit that pneumonia is caused by exposure to cold, it does not necessarily follow that the *chill* acts directly on the lung; and it is still open to us to believe that the blood is primarily affected, just as it may be in acute rheumatism. But the prevailing want of symmetry in the lung affection would seem to point to the co-operation of some more strictly local influence.

"Those, however, who maintain the unity of pneumonia—and so great an authority as Jurgensen is amongst the number, although, if I understand him aright, he would separate certain so-called typhoid forms as not croupous pneumonia at all, but only secondary lung consolidation dependent on septicæmia—those advocates of the unity of pneumonia, notwithstanding the very varying degrees of intensity with which it appears in different periods, contend that these differences are due to the different degrees of activity or malignancy of the exciting cause, of the

morbific germ, at different times and in different places;[1] and they urge in support of this view that great changes in the virulency of various pathogenic organisms have been shown under cultivation; that well-recognised infectious diseases, like scarlet fever, appear at different times with very varying degrees of virulency; that the organism characteristic of pneumonia has been found in mild as well as in severe cases; that an extreme virulency has been observed in cases which *post-mortem* examinations have shown to be cases of true croupous pneumonia. For instance, Jurgensen reports a case that ended in eight hours from the initial rigor; and Mendelsohn mentions two cases, one that of a vigorous man, 38 years of age, who died in thirty-four hours, and another case, communicated to him by a friend, that died in twenty-four hours."

Dealing with the ætiology of pneumonia, Dr. Yeo said, that most observers agreed that pneumonia sometimes occurred in connection with insanitary conditions; that, in short, there was what has been named a "pythogenic" pneumonia. But what was the real influence of exposure, of chill, as a cause of this disease? Was it simply a predisposing cause, or was it an exciting cause? That it had a causal relation of some sort to many cases of pneumonia, there seemed to him no reason to doubt; but possibly we had been in the habit of over-rating its influence as a cause. It was notorious that pneumonia often occurred during the prevalence of winds, especially the winds of spring; and not with winds from any particular quarter, for it was found to prevail with south-west winds as frequently, or more so, as with east or north-east winds. Now, in this connection, we had rather overlooked the fact, that winds were carriers of dust as well as conveyers of cold (or rather, abstractors of heat); and that while, on the one hand, they carried away heat from the surface of the body; on the other hand, they gathered up dust of all kinds, and blew all manner of micro-organisms into our air-passages. It had been noticed, again and again, that all depressing agencies might predispose to pneumonia, such as exhaustion from physical fatigue,[1] and depressing emotions; and it might be that exposure to a cold wind acts both as a predisposing cause, by the depression of the normal resisting power it produced by rapid abstraction of heat, and also as an exciting cause, by means of the micro-organisms it blew into our air-passages, especially if the view he had already suggested be correct, *that a paralytic or sub-paralytic condition of the bronchial ciliated epithelium* may in this way be induced.

A French writer, whom he had already quoted, found in the analysis of eighty cases of pneumonia, that physical fatigue was apparently a predisposing cause in a great proportion of them. And he, the speaker, had heard it said, that pneumonia occasionally occurred in public school boys after fatiguing games of football. It would be interesting to have further information on this point.

As regards the treatment of pneumonia, personally he was content to be what, in political language, was called "an opportunist." He believed in no special treatment, but in a rational common-sense management of individual cases. He was entirely opposed to all lowering methods of treatment, which were counter-indicated by the tendency to cardiac asthenia, which the concomitant pyrexia induced; and also by the consideration that those cases that supported lowering measures best, were precisely those cases which did extremely well without any active interference.

There were, however, certain circumstances, certain accidents of the disease, the treatment of which required careful consideration. These were (1) *Excessive dyspnœa*, from overwhelming pulmonary hyperæmia and œdema, in addition to the consolidation. This was the only indication he knew of for bleeding in pneumonia, and its occurrence was exceedingly rare. (2) *Excessive pyrexia*, attended with delirium and danger of rapid cardiac exhaustion. Here the cautious application of cold to the surface might be used with benefit, as advocated by Jurgensen; but we should select our patients very carefully for this mode of treatment. Quinine combined with sulphurous acid merited more frequent use for reducing temperature in low typhoid forms of pneumonia. They should be given from the *commencement* of the illness. (3) *Pain in the side.* He was in the habit of giving 5-grain doses of Dover's powder every five or six hours, in the *earliest* stage of pneumonia, to relieve pain, and he found it had an excellent influence, not only *directly*, in the relief of pain, but *indirectly*, by relieving the distress and anxiety of the patient and procuring calm sleep, and so really sparing his strength and protecting him against exhaustion later on. By relieving the pain in the side, the patient was also enabled to make deeper inspirations, and so to make the best use he could of the breathing surface that was left free to him for aërating his blood. A few leeches applied over the seat of pain was also a valuable expedient. (4) *The tendency to cardiac exhaustion, with sleeplessness and delirium.*—The so-called typhoid symptoms. The free use of alcoholic stimulants was here essential. Many cases of pneumonia required no alcohol; many other cases could only be kept alive by alcohol!

One word on the so-called abortive treatment of pneumonia by aconite. He was not ignorant of the excellent effect of aconite in certain ephemeral pyrexiæ, associated with local inflammations; and he believed it to be a valuable remedy in cases of slight pulmonary congestion with pyrexia, a condition which should be more precisely differentiated and described than it had been in our text-books. But he had no belief in an abortive treatment of acute croupous pneumonia by aconite. A consulting physician in London had told him that he had seen recently three fatal cases of pneumonia in which aconite was being "pushed." He hoped, if there was any advocate of that treatment present, he would forgive him for saying, that it was to him inconceivable how it should ever be thought right to "push" such a drug as aconite in such a disease as pneumonia.

Dr. Yeo concluded his address with some remarks on the work of the Collective Investigation Committee of the British Medical Association.

AN EXAMINATION OF THE THEORY OF AËRIAL DISSEMINATION OF SMALL-POX INFECTION.

By MONTAGUE D. MAKUNA,
Late Medical Superintendent of Fulham Small-pox Hospital.

(Continued from page 695).

The Year 1878.

The Registrar-General's Annual Summary for the year contains the following statement:—"Small-pox was fatal to 1,416 persons who, at various ages, died of that disease in London, whereas only 17 died in 19 country towns. This is in spite of the precautions taken in London, where 897 patients died in small-pox hospitals which are freely open to all. No doubt great numbers remained who were treated at their own homes, for the deaths at home were 519, and this implies a great

number of cases. What would be the result of isolating every case it is impossible to say; but it is evident that partial isolation is only partially successful, for we have 1,416 deaths in London from the disease, with five hospitals; whereas in 19 towns, with less hospital provision, there were only 17 deaths from small-pox." To this mortality in private cases Fulham contributed 18, Kensington 11, and Chelsea 4. The Metropolitan Asylums Board Hospitals admitted 4,667 patients, of whom 205 were from Fulham, 140 from Kensington, and 124 from Chelsea. The Highgate Small-pox Hospital had admitted 30 from Fulham, 15 from Kensington, and 8 from Chelsea. The total incidence of small-pox, as known to the Medical Officers of Health, was 180 in Kensington, 266 in Fulham, and 147 in Chelsea, or 592 cases for the three districts. Mr. Power's table accounts for 466 cases, and ignores the rest of the known cases as well as the concealed ones.

January.—Fulham Hospital admitted 15 acute and 63 convalescents. The acute cases were—2 from Fulham, 2 from Kensington, 6 from Camberwell, 2 from St. Giles's, and 3 from Westminster. Highgate Hospital admitted 15 from Fulham, 5 from Kensington, and 1 from Chelsea. The weekly number of cases under treatment in Fulham Hospital, beginning the 29th December, 1877, were 21, 32, 37, and 52. The Medical Officers of Health for Fulham, Kensington, and Chelsea reported 21, 8, and 7 cases respectively.

Fulham Cases.—(1) One from 13, Maxwell Road, ½ mile R., to Highgate Hospital, on the 4th. (2) One from 32, Victoria Road, ½ mile R., to Highgate Hospital, on the 13th. (3) One from 20, Peterborough Road, ½ mile R., to Highgate Hospital, on the 17th. (4 and 5) Two from 2, Harriet Street, ½ mile R., on the 22nd. (6) A labourer from 40, Hilmer Street, ¾ mile R., to Fulham Hospital, on the 6th. (7 to 17) Eleven from O. S. A., viz., 2 each from Rowan Road and Dalling Road; and 1 each from Redmore Road, Goodson Road, Brook Street, St. Peter's Square, Rose Gate, John's Road, and Southerton Road.

Kensington Cases.—(1) A disinfecting porter in the service of Paddington Vestry, from 66, Ifield Road, C. C., on the 26th, to Fulham Hospital. He took it while disinfecting articles with small-pox infection. (2) One from 82, Cromwell Road, 1 mile R., to Highgate Hospital, on the 25th. (3 to 7) Five from O. S. A., viz., 2 from Westbourne Grove, and 1 each from Sunbrook Road, Clarendon Mews, and Hunt Street.

One Chelsea case was from Keppel Street, O. S. A.

Fulham Small-pox Hospital was closed to acute cases about the middle of October, 1877, and re-opened for acute cases on the 25th January, 1878. The history of the above given cases clearly demonstrates that the disease was undergoing recrudescence in the Special Area when Fulham Hospital was closed, and the foci of infection were multiplying. Thus in ignoring the admission of fifteen cases to Highgate Hospital, Mr. Power miscalculated the time and incidence of the disease.

February.—Fulham Hospital admitted 73 acute cases and 116 convalescents. The acute cases were—13 from Fulham, 9 from Kensington, 6 from Chelsea, 6 from St. Giles's, 8 from Camberwell, 5 from Westminster, 7 from Wandsworth, 8 from Paddington, 7 from St. George s, and 4 from Strand. Highgate Hospital admitted 14 from Fulham, and none from Kensington and Chelsea. According to the Medical Officers of Health, the monthly incidence of the disease was 39 in Fulham, 10 in Kensington, and 7 in Chelsea. The weekly number of cases under treatment in Fulham Hospital were 72, 100, 108, and 166.

Fulham Cases.—(1) A ward servant of the Fulham Hospital was taken ill and entered as a Fulham case on the 15th. (2) One from 3, Garden Cottages, C. C., to Highgate Hospital, on the 19th. (3) One from 9, Peterborough Road, ½ mile R., on the 2nd. Infected street. (4 and 5) Two from 58, Victoria Road, ½ mile R., to Fulham Hospital, one in a neglected and convalescent state on the 3rd, the other on the 13th. From a concealed case. Infected street. (6 and 7) Two from 18, Maxwell Road, ½ mile R., to Fulham Hospital on the 6th and 8th. Infected street. (8) One from 12, Richmond Place, ½ mile R., to Highgate Hospital, on the 13th. (9 and 10) Two from Waterford Road, ½ mile R., to Highgate Hospital, on the 15th and 22nd. (11) One from 28, Stanley Road, ½ mile R., on the 20th. (12) One from 10, Hilmer Street, ¾ mile R., to Fulham Hospital, on the 4th. Infected street. (13 and 14) Two from 21, May Street, ¾ mile R., to Fulham Hospital. Infected by the non-resident hospital staff. (15) One from 10, Dawson Street, 1 mile R., on the 21st. (16 to 27) Twelve from O. S. A., viz., two from 10, Hanover Cottages (infected house), and one each from Brook Street (infected), Trafalgar Street, Simpson's Place (a neglected case), Paradise Row, Munden Street (infected), Raynham Road (infected), Waterloo Street, Rowan Road (infected), Dalling Road (infected), and Black's Road.

Kensington Cases.—(1) A female from 93, Ifield Road, C. C., to Fulham Hospital, on the 20th. Her daughter from the same house, an imported case, previous year. The latter was now a ward servant in Fulham Hospital. (2) A dressmaker from 172, Fulham Road, ½ mile R., on the 13th. By visiting her mother in Lambeth, who was removed to Stockwell Hospital. (3) A cook from 36, Warwick Road, ½ mile R., on the 21st. (4) A draper's assistant from 44, Earl's Court Road, ¾ mile R., on the 16th. (5 to 9) Five from O. S. A., viz., 1 each from Portland Road, Fowell Street, Treverton Street, Ladbroke Grove Road, and Brunswick Mews.

Chelsea Cases.—Six from O. S. A., viz., 2 from Cheyne Row, and 1 each from Pond Place, Pavilion Road, Sloane Street, and King's Road. Thus it will be observed that in January and February there were 27 cases in the Special Area, of which 21 were from Fulham, 6 from Kensington and none from Chelsea. I have pointed out this unequal distribution of cases in the three districts in the history of the previous year, and yet Mr. Power accounts for some of them by his method of calculation as from the three districts equally.

March.—Fulham Hospital admitted 123 acute cases and 125 convalescents. Of the acute cases, 37 were from Fulham, 16 from Kensington, 29 from Chelsea, 17 from Wandsworth, 7 from St. George's, 6 from Strand, 5 from St. Giles's, 4 from Westminster, and 2 from Paddington. Highgate Hospital admitted 1 from Fulham, 2 from Kensington, and 1 from Chelsea. The Medical Officers of Health for Fulham, Kensington, and Chelsea reported 38, 16, and 31 cases respectively. The weekly number of cases under treatment at Fulham Hospital were 202, 234, 207, 206, and 203. At this time the *West London Observer* contained much correspondence and many articles regarding concealment of cases, want of sanitary measures, halting of ambulances near public-houses, visits of the hospital staff in the vicinity of the hospital, actions of the qualified and unqualified small-pox curers. The magistrate was several times applied to, to isolate the cases in hospitals. At this time also a firm of builders, who were erecting streets in the immediate vicinity of the hospital, failed in their extensive speculations outside London; and the agitators against Fulham Hospital and the prosecutors of the Hampstead Hospital found in it an argument that the depreciation of property and building failures were due to Fulham Hospital. I prepared a statement for the Managing Committee of the hospital, to answer certain allegations made against the hospital by some members of the Kensington Vestry;

*

but they refused to forward it to Dr. Dudfield, on the ground that it was impolitic to give him information which might be used against the managers in the court. In answer to my enquiries, one medical man wrote to me that he had had cases of small-pox in Ifield Road and Finborough Road since October, 1877; and he attributed the disease to non-isolation of convalescents at home, and visiting of the hospital staff in that neighbourhood. Other medical men stated they had cases before the hospital was re-opened and subsequently, but they refused to give particulars. I had come to know that occupiers of small shops in Ifield Road, Fulham Road, and adjoining streets had cases at home, and that the persons attending the sick also served at the counters. When the cases were successfully concealed, they left lodgings infected and carried infection with them.

Fulham Cases.—(1) One from 17, Farm Lane, C. C., to Fulham Hospital, on the 7th. Infected street. (2) One from 1, Garden Cottages, C. C., to Fulham Hospital, on the 15th. (3) One from 16, Melroth Place, ½ mile R., to Fulham Hospital, on the 9th. (4) A cab-driver from 12, Richmond Place, ½ mile R., on the 10th. (5 to 8) Three from 14, Stamford Road, ½ mile R., 1 on the 11th, and 2 on the 27th; 1 from No. 11, on the 28th. (9) A laundress from 19, Moor Park Terrace, ½ mile R., on the 28th. (10) One from 20, Mund Street, ¾ mile R., to Fulham Hospital, on the 1st. (11) One from 13, Bramber Road, ¾ mile R., to Fulham Hospital, on the 2nd. (12) One from 16, Star Lane, ¾ mile R., to Fulham Hospital, on the 5th. Concealed cases in the street. (13) A homeless man, removed from his sister's house in North End Road, ¾ mile R., on the 16th. (14) One from 5, King's Terrace, ¾ mile R., on the 24th. (15) One from 3, Cambrian Terrace, ¾ mile R., on the 30th. (16) One from 3, Thorpe Terrace, 1 mile R., on the 11th. (17 to 38) Twenty-two cases, O. S. A., viz., 1 each from Paradise Row, Raynham Road, York Road, Redmore Terrace, Church Lane, Simpson's Place, Bullow Road, King Street, Felgate Mews, Hanover Cottages, Anne's Place, Latimer Road, Gillard's Place, Campbell Street, Adelaide Terrace, Bridge Street, Chancellor Street, Paradise Cottages, Brook Green Lane, Dalling Road, and 2 from Great George Street. Most of the houses and streets were previously infected.

Kensington Cases.—(1) One from 11, North Street, C. C., to Fulham Hospital, on the 9th. (2) One from 4, South Street, C. C., to Fulham Hospital, on the 31st. (3) One from 29, Ifield Road, C. C., to Fulham Hospital, on the 7th. (4) A housemaid from 18, Bolton Gardens, ½ mile R., on the 8th. (5) A domestic from 26, Cathcart Road, ½ mile R., on the 19th. Infected by a case treated at home. (6) One from 12, Ashley Cottages, ¾ mile R., by visiting her parents in Faroe Road. (7) A page from 9, Bina Gardens, ¾ mile R., on the 19th. (8) One from 90, Warwick Gardens, 1 mile R., on the 26th. (9) A domestic from Kensington Infirmary, 1 mile R., on the 30th. (10 to 18) Nine from O. S. A., viz., 3 from 2, Silchester Gardens, and 1 each from Peel Street, Norland Terrace, Pennant Mews, Portobello Road, Queen's Gate, and High Street, Notting Hill.

Chelsea Cases.—(1) One from 16, Maude Grove, ½ mile R., to Fulham Hospital, on the 14th. (2) A student from St. Mark's College, ½ mile R., to Highgate Hospital, on the 26th. (3 and 4) Two from 58, Slaidburn Street, ¾ mile R., to Fulham Hospital, on the 10th and 11th. They took the disease from No. 27. (5 and 6) One each from 43 and 30, Slaidburn Street, ¾ mile R., to Fulham Hospital, on the 26th and 28th. Many infected houses in the street. (7) One from 4, Mill Terrace, ¾ mile R., to Fulham Hospital, on the 8th. (8) One from 24, Riley Street, ¾ mile R., to Fulham Hospital, on the 14th. (9) A domestic from 37, Gertrude Street, ¾ mile R., to Fulham Hospital, on the 27th. (10) One from 9, Little Camera Street, ¾ mile R., to Fulham Hospital, on the 29th. (11 and 12) A cook from 96, and a shopwoman from 44, Beaufort Street, 1 mile R., to Fulham Hospital on the 23rd and 27th. (13 to 30) Eighteen from O. S. A., viz., 3 each from Francis Street and Paradise Walk, 2 from White Lion Street and Danver's Buildings and 1 each from Cole Street, North Street, Hasker Street, Charles Street, Keppel Street, Christchurch Street, Benson Terrace, and Caversham Street.

April.—Fulham Hospital admitted 203 acute cases, and 40 convalescents. The acute cases were 56 from Fulham, 49 from Kensington, 23 from Chelsea, 25 from Wandsworth, 21 from St. George's, 14 from St. Giles's, 9 from Paddington, 3 from Strand, and 3 from Westminster. Highgate Hospital admitted 6 from Kensington, and 2 from Chelsea. Dr. Dudfield reported 57 fresh cases in Kensington during the four weeks ending 1st May, of which 10 were treated at home. The Medical Officer for Fulham reported 65 fresh cases of which 8 were treated at home. The Medical Officer of Health for Chelsea reported 28 fresh cases. The weekly number of cases under treatment at Fulham Hospital during four weeks ending 27th April, were 188, 204, 246, and 202. It was stated by several medical men that the westerly winds carried the infection from the hospital area and spread the disease in the locality. Dr. Dudfield investigated the question and found that the majority of the cases were reported during the second fortnight of the month, and they might have been infected when the winds were principally easterly or south-westerly. Another stated that it was due to visitation of the sick by their friends; another, that it was due to the visits paid by the members of the hospital staff to their friends; another to ambulances. Dr. Dudfield believed that the spread was due to concealment of cases, premature exposure of convalescents, infected clothing of attendants on sick at home, laundries, neglect of vaccination, re-vaccination, &c. A striking case was reported to him by a medical man, who, one Saturday night, saw a laundress with the disease well out on her. That very day she had sent home the washing of her customers dried in her room. Another laundress fell ill and her husband nursed her, the business being conducted as usual. There were sixteen lodgers in the house who all left, with the probable result of sowing the disease broadcast. The husband fell ill subsequently and was sent to the hospital.

Fulham Cases.—(1) One from 23, Seagrove Road, C. C., to Fulham Hospital, on the 28th. (2) One from 54, Hildyard Road, C. C., to Fulham Hospital, on the 11th. (3 and 4) One from 14 (an infected house), and 1 from 32, Stamford Road, ½ mile R., on the 16th and 20th respectively. (5 and 6) A child from 19, and another from 20, Moor Park Terrace, ½ mile R., on the 7th and 29th respectively. (7 to 9) Three children from 2, Golding's Buildings, ½ mile R., 1 on the 10th and 2 on the 25th. (10 and 11) A dressmaker from 12 (an infected house), and another from 5, Richmond Place, ½ mile R., on the 20th and 2nd. (12 and 13) Two from 4, Ashton Road, ½ mile R., on the 10th and 19th. (14) One from 5, Waterford Road, ½ mile R., on the 11th. (15 to 18) Four from May Street, ¾ mile R. (an infected street); a wheelwright from 4, on the 11th; a painter from 40, on the 11th; a carpenter from 43, on the 14th, and his wife, on the 29th. (19) One from 45, Rylston Road, ¾ mile R., on the 9th. (20) One from 1, Orchard Street, ¾ mile R., on the 11th. (21) One from 3, New King's Road, ¾ mile R., on the 14th. (22) One from 28. Dieppe Street, ¾ mile R., on the 22nd. (23 to 25) Three from 14, Field Road, 1 mile R. (infected street); 1 on the 18th, and 2 on the 30th. (26) One from 2, Edwin Terrace, 1 mile R., on the 16th. (27) One from 9, Wyatt's Terrace, 1 mile R. (infected street), on the

27th. (28) One from 6, John's Street, 1 mile R., on the 29th. (29 to 56) Twenty-eight from O. S. A., viz., 5 from 5, Blythe Terrace, 5 from two houses in Great George Street; 2 each from Bridge Street, South Street; 1 each from Brunswick Cottages, Cambridge Road, Henrietta Place, Stow Road, Queen Street, Dungannon Terrace, Westbourne Park Road, Hanover Cottages, Distillery Lane, Trafalgar Street, Faroe Road, Devonshire Street, Serf's Cottage, and Felgate Mews.

Kensington Cases.—(1 to 7) Seven from Ifield Road, C. C., viz., A child and a bricklayer from 77, on the 17th and 19th, infected in Fulham; a paper-stainer's boy from 28, on the 18th; 1 from 91, on the 18th; a charwoman working in the street, from 106, on the 19th; a woman, only a day in the house, from 110, having changed lodgings from Lambeth, about the 20th; a laundress from 112, on the 16th. (8) A housemaid from 178, Finborough Road, C. C., on the 17th, from her mother's house in Stamford Terrace. (9) A domestic from 7, South Street, C. C., on the 21st, she was sent home ill from the place of her service, outside the parish. (10 and 11) A labourer from 6, and a coach-painter from 7, North Street, C. C., on the 3rd and 5th. (12) A schoolboy from 20, St. Mark's Road, C. C., on the 17th. (13 to 16) Four from Richmond Road, ½ mile R.; a servant from 58, on the 13th; a potman from Richmond Arms, on the 18th, he took it from an ambulance driver; a domestic from 96, on the 20th; a child from 73, on the 22nd. (17 to 19) Three from Redcliffe Gardens, ½ mile R.; a cook from 52, on the 16th; a housemaid from 34, on the 18th; a cook from 8, on the 29th. (20) One from 24, Redcliffe Mews, ½ mile R., on the 18th. (21 and 22) A female from 26, and a child from 14, Seymour Place, ½ mile R., on the 24th and 16th. (23 and 24) A housekeeper from 53, and another from 6, Hollywood Road, ½ mile R., on the 19th and 18th. (25) A barman from 214, Fulham Road, ½ mile R., on the 18th. (26 to 28) Three from Kempsford Gardens, ½ mile R.; 1 from 27, on the 15th, from a case treated at home; a domestic from 33, on the 22nd, engaged to marry an hospital porter; a clerk from 12, on the 25th, recently changed his lodgings to the above address. (29) A servant from 59, Eardley Crescent, ½ mile R., on the 19th. (30) A servant from 6, Warwick Road, ½ mile R., on the 19th. (31) A servant from 21, Earl's Court Square, ½ mile R., on the 18th, from a sempstress engaged during the day, who had two children ill at Fulham. (32) One from 179, Earl's Court Road, ½ mile R., on the 19th. (33) A child from 12, Child Street, ¾ mile R., on the 18th (infected street). (34) One from 3, Clifton Place, ¾ mile R., on the 18th. (35) A butler from 20, Collingham Road, ¾ mile R., on the 20th. (36) One from 11, Walgrave Road, ¾ mile R., on the 24th. (37) One from 18, Queensbury Mews, 1 mile R., on the 1st. (38) One from 9, Pembroke Place, 1 mile R., on the 23rd. (39 to 55) Seventeen from O. S. A., viz., 2 from St. Evan's Road, 1 each from Portland Road, Adia Terrace, Essex Villas, Catherine Road, Norfolk Terrace, South End, Peel Street, Portland Cottages, St. Clement's Road, Newcombe Street, Lonsdale Road, Bedford Gardens, Richmond Road, Ladbroke Road, and Talbot Road,

Chelsea Cases.—(1 and 2) One each from 40 and 41, Slaidburn Street, ½ mile R., on the 10th and 24th. An old haunt of infection. (3) One from Milton House, Maude Grove, ½ mile R., on the 21st. (4) One from 23, Lot's Road, ½ mile R., to Fulham Hospital, on the 27th. (5) One from 43, Lot's Road, ½ mile R., to Highgate Hospital, on the 2nd. (6 and 7) One from 37, and a laundress from 33, Luna Street, ¾ mile R., on the 3rd and 18th. (8) One from 9, Little Camera Street, ¾ mile R., on the 16th. (9) One from 8, Foundry Place, ¾ mile R., on the 19th. (10) One from 333, Fulham Road, ¾ mile R., on the 22nd. (11) One from The Rectory, Church Street, 1 mile R., on the 16th. (12) One from 72, Camera Square, 1 mile R., on the 17th. (13) One from 2, Carlyle Square, 1 mile R., on the 19th. (14) One from 4, Alfred Cottages, 1 mile R., on the 20th. (15 to 25) Eleven from O. S. A., viz.:—1 each from Shewon Terrace, Christchurch Street, Park Walk, Marlborough Road, Britton Street, Francis Street, Flood Street, Rawling's Street, Langston Street, Oakley Crescent, and King's Road. Most of the Kensington cases in S. A. were servants, and Fulham cases were caused by concealed cases.

May.—Fulham Hospital admitted 172 acute cases, viz.:—49 from Fulham, 35 from Kensington, 34 from Chelsea, 20 from Wandsworth, 17 from St. George's, 7 from Paddington, 4 from St. Giles's, 2 from Strand, and 2 from Westminster. Highgate Hospital admitted 1 from Fulham, 1 from Kensington, and 4 from Chelsea. Dr. Dudfield reported 55 fresh cases in Kensington, of which 20 were treated at home. The Medical Officer of Health reported 65 cases during the month, Fulham parish contributing 46, of which 16 were treated at home; the remaining 19 occurred in Hammersmith. The Chelsea Medical Officer of Health reported 44 fresh cases. The local papers were filled with information on concealment of cases, especially in the district of North End and May Street, and a correspondent wrote, "If the medical practitioners of this and neighbouring districts would (instead of indulging, as it is to be feared more than one of them does, in either selfishness or sentimentality, or a combination of both) make it their duty in the interest of the community at large, which is justly entitled to consideration, to report all cases to health authorities—they at least would be clear when the question is asked, with whom lies the responsibility of such a reprehensible state of things?" Dr. Dudfield was asked by the Kensington Vestry to answer certain allegations against Fulham Hospital. He made a special report on the subject, and gave the following history of some of the cases in the immediate vicinity of the hospital:—

"It will have been noticed that the largest number of cases have occurred in Ifield Road, a long and very populous (not to say over-crowded) street, where there have been 15 cases in 11 houses. One of the first of the cases was that of a man who refused to go to the hospital and who died on the 19th April, after eight days' illness. His widow then sickened and passed through her illness at home. Within a few doors from this house there have been several other single cases which were removed to the hospital. In another house a man passed through his illness, having refused to go to the hospital. In another house three sisters were successively attacked after the customary interval for incubation, the family declining our offers, on two occasions, to disinfect the rooms, &c., having, as they said, carried out some directions of their medical attendant which they deemed sufficient. After the occurrence of the third case we insisted on doing the work, and since then there has not been any further case.

"At Finborough Road and at Adrian Terrace, which are intimately connected with Ifield Road, cases have occurred, and in each road there has been a death from small-pox.

"At Kempsford Gardens a married woman was nursed at home by her husband, who afterwards took the disease, and was sent to hospital. In this street there have been four other cases in as many houses.

"From South Street, St. Mark's, a woman was removed on the third day of the eruption, and it is stated that during her illness the linen of families was washed and dried in the sick-room. In this and contiguous streets eight other cases have occurred in March, April, and May.

"At Thistle Grove a case occurred, and was con-

cealed until two other cases happened, and then the people were glad to send the new cases to hospital.

"At Redcliffe Street three children were ill in one house. No doctor was called in, and nothing was known of the occurrence until after the children had recovered."

The weekly number of cases under treatment during the five weeks ending 1st June, was 198, 199, 192, 182, and 165.

Fulham Cases.—(1) A gardener from 70, Farm Lane, C. C., on the 11th, to Fulham Hospital, by visiting an ill friend in the same street. (2) One from 14, North Street, C. C., to Fulham Hospital, on the 15th. (3) One from 10, Rickett Street, C. C., to Fulham Hospital, on the 24th. (4) One from 26, Stamford Road, ½ mile R., to Fulham Hospital, on the 6th. (5) One from Prince's Mews, ½ mile R., to Fulham Hospital, on the 13th. (6) One from 18, Bective Road, ½ mile R., to Fulham Hospital, on the 22nd. (7) One from 23, Lot's Road, ½ mile R., to Fulham Hospital, on the 26th. (8 and 9) One from 1, and 1 from 8, Richmond Place, ½ mile R., on the 14th and 21st. Infected houses. (10 and 11) Two from St. John's Place, ½ mile R., on the 14th and 15th. A case from the same house last month. (12 and 13) Father and son from May Cottage, May Street, ¾ mile R., on the 6th and 22nd. Many concealed cases in the street. (14 and 15) Two from 1, Star Lane, ¾ mile R., on the 2nd and 30th. Infected Street (16 and 17) One from 11, and one from 17, Dieppe Street, ¾ mile R., to Fulham Hospital, on the 3rd and 14th. (18) One from 8, Little Ebenezer Place, ¾ mile R., on the 4th. (19) One from 1, Simmons' Cottages, ¾ mile R., on the 5th. (20) One from 20, King's Terrace, ¾ mile R., on the 6th. (21) One from 20, Ansford Cottages, ¾ mile R., on the 10th. (22) One from Normandy Cottage, ¾ mile R., on the 19th. (23) One from 9, Bramber Road, ¾ mile R., on the 31st. (24) A baby from 19, Field Road, 1 mile R., on the 6th. Infected House. (25) One from 24, Grove Terrace, 1 mile R., on the 4th. (26) One from the "The Three Kings," 1 mile R., on the 30th. (27) One from 5, Field Terrace, 1 mile R., on the 30th. (28 to 50) Twenty-three from O. A. S., viz., 3 from Felgate Mews, 2 each from Nasmythe Street, Hanover Cottages, Raynham Road, and Devonport Road; 1 each from Devonshire Street, "Red Cow," Model Buildings, Elm Place, Melina Road, Trafalgar Street, Raynham Road, Morby's Buildings, Masboro' Road, The Mall, Horace Mews, Melbourne Terrace, and Elrick Street.

Kensington Cases.—(1 to 7) Seven from Ifield Road, C. C.; a child from 60, on the 1st; 2 laundresses from 112, on the 5th and 18th; a stableman from 110, on the 6th; a bricklayer from 40, on the 7th; a boy from 21, on the 15th; and a girl from 34, on the 19th. (8) A domestic from 137, Finborough Road, ½ mile R., on the 14th. (9) One from 176, Earl's Court Road, ½ mile R., on the 29th. (10) A child from 8, Penywern Road (a school), ½ mile R., on the 8th. (11 and 12) One from 21, and a child from 41, Kempsford Gardens, ½ mile R., on the 17th; small-pox in neighbouring houses, the latter caught it from washing in a laundry. (13) A laundress from 54, Seymour Place, ½ mile R., on the 24th. (14) One from 15, Eardley Crescent, ½ mile R., on the 23rd. (15 and 16) Two boys from 38, Thistle Grove, ¾ mile R., on the 2nd and 3rd, from a concealed case. (17) A servant from 274, Fulham Road, ¾ mile R., on the 17th. (18) One from 8, Gledhow Terrace, ¾ mile R., on the 9th. (19) One from 38, Courtfield Gardens, ¾ mile R., on the 25th. (20) One from 53, Onslow Gardens, 1 mile R., on the 7th. (21 to 36) Sixteen from O. S. A., viz., 5 children from 13, Gadsden Mews; 1 each from Chelsea Grove, South End, Bosworth Road, Bramley Road, Elvaston Mews, Hazlewood Crescent, Walmer Road, Holland Road, Dartmoor Street, Orchard Street, and Tavistock Crescent.

Chelsea Cases.—(1) One from Cottage Laundry, Limerston Street, ½ mile R., on the 18th. (2 and 3) Two students from St. Mark's College, ½ mile R., to Highgate Hospital, on the 11th and 13th. Infected house. (4) One from 39, Seaton Street, ¾ mile R., on the 6th. (5 and 6) Two from 20, Callow Street, ¾ mile R., on the 17th and 27th. (7) One from 56, Park Walk, ¾ mile R., on the 19th. (8 to 10) Three children from 56, Beaufort Street, 1 mile R., to Fulham Hospital, on 8th, 18th, and 21st. (11 and 12) One from 31, and the other from 98, Church Street, 1 mile R., on the 12th and 20th. (13) One from 37, Paulton Square, 1 mile R., on the 18th (14) One from 7, Arthur Street, 1 mile R., on the 22nd. (15 to 38) Twenty-four from O. S. A., viz., 4 from 9, George's Place, 2 from Walton Street and Keppel Street; 1 each from Flood Street, Oakley Crescent, Upper Cheyne Row, Francis Street, Moss Place, Badcock Street, Redsdale Street, Stratham Place, St. Hilda Terrace, Langston Street, Exeter Place, Lincoln Street, College Place, High Street, Danver Street, and Milner Street. It is noticeable that most of the cases in C. C. seem in Ifield Road. By what law this selection of the street to the exclusion of others can be accounted for is not evident to me. Another point is, that the Special Area of Chelsea has suffered the least, because the haunts of infection are away from the hospital.

June.—Fulham Hospital admitted 88 cases, viz., 20 from Fulham, 18 from Kensington, 16 from Chelsea, 8 from St. George's, 15 from Wandsworth, 6 from Paddington, 2 from St. Giles's, 2, from Westminster, and 1 from Strand. Highgate Hospital admitted 3 from Kensington. Dr. Dudfield reported 23 cases in Kensington during four weeks ending June 26th. The Medical Officer of Fulham reported 20 fresh cases, of which 17 occurred in Fulham parish. The Medical Officer of Health for Chelsea reported 18 fresh cases. The weekly number of cases under treatment at Fulham Hospital during four weeks ending June 29th, were 147, 141, 133, and 121.

Fulham Cases.—(1) A hospital nurse was taken ill, and entered as a case on the 28th. (2) One from 4, Roxby Place, C. C., on the 13th, from concealed cases. (3) One from 8, Richmond Place, ½ mile R., on the 7th. Infected house. (4 to 6) Three from Stamford Road, ½ mile R., 2 from 11, on the 5th, and 1 from 37, on the 7th. (7) One from Cambridge Terrace, ½ mile R., on the 18th. (8) One from 93, Rylstone Road, ¾ mile R., on the 5th. (9 to 11) Three from Estcourt Road, ¾ mile R., a child from 13 (a baby form), on the 11th, 1 from 52, on the 14th, and 1 from 16, on the 22nd. (12) One from 9, Pownal Road, ¾ mile R., on the 13th. (13) One from 17, William Street, ¾ mile R., on the 26th. (14) One from 94, May Street, ¾ mile R., on the 23rd. (15) One from Field Terrace, 1 mile R., on the 17th. (16 to 20) Five from O. S. A., viz., 1 each from The Grove, Chelmsford Street, Dungannon Terrace, Overton Road, and Queen's Place.

Kensington Cases.—(1) One from 7, Ifield Road, C. C., on the 13th. (2 and 3) Two from Finborough Road, ½ mile R., 1 from 81, on the 10th, she came to live here from Bermondsey on the 6th; a nurse from 144, on the 21st. (4) A domestic from 12, Bolton Gardens, ½ mile R.; she took it from her mother's house in Fulham. (5) A domestic from 26, Onslow Square, 1 mile R., on the 18th. (6) A boy from 1, Merton Road, 1 mile R., on the 12th. (7 to 21) Fifteen from O. S. A., viz., 2 each from Dartmoor Road, Bomore Road; 1 each from Kensington Place, Tavistock Crescent (infected house), Absolom Road, Yeoman's Row, Radley Mews, Phillimore Mews, Charlesville Road, Bosworth Road, Moscow Road, Kensington Dispensary, and Prince's Gate.

Chelsea Cases.—(1 and 2) Two brothers from 25, Lot's Road, ½ mile R., on the 7th and 12th. Small-pox

in the next house. (3) One from 20, Callow Street, ¾ mile R., on the 17th. Infected house. (4) One from 39, Luna Street, ¾ mile R., on the 20th. (5) One from 55, Seaton Street, ¾ mile R., on the 14th. (6 to 16) Eleven from O. S. A., viz., two each from Guthrie Street, North Street, Elm Park Terrace, Caledonian Road; and one each from York Mews, Danver's Buildings, and Ives Street. Most of these houses were infected. The local papers contained accounts of many concealed cases in Fulham, and the spread of the disease from two public-houses, the "Three Kings," and the "Rose and Crown." It was stated that many families stricken with small-pox in the North End, left the houses infected, and others who followed them took the disease.

July.—Fulham Hospital admitted 31 acute cases, viz., 12 from Fulham, 5 from Kensington, 4 from Chelsea, 5 from St. George's, 2 from Paddington, 2 from Westminster, and 1 from Wandsworth. The weekly number of cases under treatment at Fulham Hospital during the four weeks ending 27th July, was 98, 76, 72, and 56.

Fulham Cases.—(1) One from 25, Seagrove Road, C. C., to Fulham Hospital, on the 10th. An infected house. (2 and 3) One from 10, and another from 4, Rickett Street, C. C., on the 24th and 22nd. Infected houses and concealed cases. (4) One from 8, Farm Lane, C. C., on the 19th. Infected street. (5) One from 18, Stamford Road, ½ mile R., on the 4th. Infected street. (6) One from 1, Jackson's Place, ½ mile R., on the 15th. (7) One from 19, Prince's Terrace, ½ mile R., on the 18th. (8 to 10) Three sisters from 34, Pownal Road, ¾ mile R., two on the 5th, and the other on the 19th. (11) One from 11, Crown Street, ¾ mile R., on the 16th. (12) One from 5, Field Terrace, 1 mile R., on the 8th. Infected street.

Kensington Cases.—(1) A nurse from 55, Earl's Court Square, ½ mile R., on the 7th. (2) One from 12, Merton Road, 1 mile R., on the 17th. (3 to 5) Three from O. S. A., viz., 1 each from Argyll Road, Dartmoor Street, and Duke's Lane.

Chelsea Cases.—(1) One from 20, Gunter Grove, ½ mile R., on the 23rd. (2 to 4) Three from O. S. A., viz., 1 each from Radnor Street, Lower George Street, and North Street.

August.—Fulham Hospital admitted 8 acute cases, viz., 1 from Fulham, 4 from St. George's, 2 from Westminster, and 1 from Wandsworth. The weekly number of cases under treatment during five weeks ending 31st August, were 45, 40, 33, 22, and 16. The Fulham case was from 32, Peterborough Road, ½ mile R., on the 11th.

September.—Fulham Hospital admitted 3 acute cases, viz., 2 from St. George's, and 1 from 2, Shalcombe Street, ¾ mile R., on the 26th. A Chelsea case.

October.—Fulham Hospital admitted 7 acute cases: 1 from 8, Rear Gate, ½ mile R., on the 30th, a Fulham case; 2 from 2, Shalcombe Street, Chelsea, ¾ mile R., on the 9th, an infected house; and 4 from other districts.

November.—Fulham Hospital admitted 18 acute cases, viz., 2 from Fulham, 3 from Chelsea, 1 from Kensington, O. S. A., and 12 from other parishes. The Fulham cases were—1 each from 20, Moor Park Terrace, and 24, Waterford Road, ½ mile R., on the 17th and 27th. The Chelsea cases were 2 from 17, Slaidburn Street, ½ mile R., on the 6th (infected house), and 1 from 25, Limerston Street, ¾ mile R., on the 7th. Infected house.

December.—Fulham Hospital admitted 19 acute cases, viz., 6 from Fulham, and 13 from other parishes.

Fulham Cases.—(1) One from 3, Garden Row, C. C., on the 27th. (2) One from 24, Waterford Road, ½ mile R., on the 10th Infected house. (3) A baby from "Norfolk Arms," ¾ mile R., on the 29th. (4) A baby from 69, Rylstone Road, ¾ mile R., on the 31st. (5) One from 6, Caroline Place, 1 mile R., on the 27th. (6) One from 5, Hatfield Street, 1 mile R., on the 27th.

Thus closed the year 1878, in which much damage in the S. A. of Fulham had been caused; many houses were left infected, and new cases cropped up at the end of the year to serve as foci for fresh outbreaks during the following year.

MIDWIFERY IN SOUTH AFRICA.

By CHARLES JAMES EGAN, B.A., Tc.D., M.R.C.S., Eng., L.K.Q.C.P., Irel.

SOME years since I contributed to this journal a paper on "Midwifery in Kaffraria, South Africa" (*Medical Times and Gazette*, November 25th, 1871), in which I gave a statistical table of 400 cases. I now send a report of 600 further cases attended by me since that time:—

TABLE I.

Nature of Case.	Primiparæ.	Multiparæ.	Total.	Deaths of Mothers. Multiparæ.	Deaths of Mothers. Primiparæ.
Natural	91	333	424	—	—
Premature	6	30	36	4	—
Tedious	8	6	14	—	—
Twins	3	6	9	—	—
Breech...	1	3	4	—	—
Version	4	20	24	—	—
Forceps	23	11	34	—	—
Craniotomy	—	1	1	1	—
Induction premature labour	—	1	1	—	—
Partial placenta prævia ...	1	2	3	—	—
Placenta prævia	1	3	4	—	—
Flooding	6	14	20	—	—
Convulsions	1	1	2	—	1
Puerperal mania	2	—	2	—	—
Adherent Placenta... ...	3	7	10	—	—
Hydrops amnii	—	5	5	—	—
Phlegmasia dolens	1	3	4	—	—
Peritonitis	—	1	1	1	—
Metritis	1	3	4	—	—
Totals	152	450	602	6	1

TABLE II.

No. of Cases.		No. of Children.	
Primiparæ	152	Males	333
Multiparæ	450	Females...	287
Total	602	Total	620

I have, as accurately as possible, noted the lengths of the first and second stages of labour in these cases, and have compiled the following tables:—

TABLE III.

MALES.	Primiparæ.	Multiparæ.
No. of births	86	237
Length of 1st Stage	12h 30m	6h
Length of 2nd Stage	1h 30m	42m
Length of both Stages	14h	6h 40m

Average of whole number, both Primiparæ and Multiparæ.

No. of cases	323
Length of 1st Stage	7h 40m
Length of 2nd Stage	50m
Length of both Stages	8h 40m

TABLE IV.

FEMALES.	Primiparæ.	Multiparæ.
No. of cases	66	213
Length of 1st Stage	11h 40m	6h 36m
Length of 2nd Stage	1h 20m	38m
Length of both Stages	12h 21m	7h 15m

Average of whole number, both Primiparæ and Multiparæ.

No. of cases	279
Length of 1st Stage	7h 36m
Length of 2nd Stage	1h
Length of both Stages	8h 24m

TABLE V.

Average of the whole series, Male and Female.

No. of cases	602
Length of 1st Stage	7h 40m
Length of 2nd Stage	50m
Length of both Stages	8h 30m

The statistics of this series of cases will be found to bear a great similarity to those previously published by me. The length of the labour is found to be somewhat shorter—in the first series it was found to be about nine hours, in this one eight hours and a half. This difference may perhaps be accounted for by the more frequent use of forceps, as I do not allow cases to remain unassisted so long now as I formerly did. The percentage of forceps cases in the first series was 4·5, in this series 5·6. And I now consider it is much better practice to use forceps early, even in cases that you feel sure would be delivered without their use, but when of necessity the second stage must be much prolonged.

Cross births, requiring turning, amounted to 4·5 per cent. in the first series, in this series to 4·0 per cent. In a paper published in the *Medical Times and Gazette*, October 27th, 1883, by Dr. M'Craith, on "Position in Midwifery Practice," he speaks of the difficulty in turning in the English position, in cases where the child lies with its back to the mother's abdomen; and in speaking of the use of the left hand in such cases, exclaims, "Can anything be more stupid than this? *Fiat experimentum in corpore vili.*" However, in every case in which the child lay in that position, viz., with its back to the mother's abdomen, I have always turned with my left hand, the mother lying in the English position; and such cases formed fully one-half of the cases in the series, and I think that an accoucheur ought "to have a right hand on his left shoulder for that purpose."

Cases of flooding were more numerous in the first series, showing an average of 5·3 per cent. The present series give 3·3 per cent., and in none of them have I been obliged to resort to injections of Tinct. Ferri Perchlor, pressure over the uterus and injections into the uterus of cold water being sufficient. This difference arises, I think, from more care being taken in keeping pressure with the hand on the uterus between the birth of the child and the coming away of the placenta; and when the labour pains were in any way weak, or the intervals between them long, giving a dose of ergot, as the head was pressing on the perinæum.

An account of three of the cases under the head of Hydrops Amnii was published by me in the *Medical Times and Gazette*, January 9th, 1875, with some remarks on this complication. Since then I have had two well-marked cases of this nature. In the first of these I was called to attend after the second stage had lasted for more than three hours, when I found the os fully dilated, with a dense membrane stretched across it, and no advance made by the pains. I ruptured the membranes, which were very tough, and nearly four gallons of water escaped. The child was born dead shortly afterwards, and some hæmorrhage occurred.

In the second case I was called to attend early; and as soon as ever the os was dilated, I gave a dose of ergot, and ruptured the membranes. Over three gallons of water came away, and by keeping good pressure over the uterus with a binder, the child's head immediately entered the pelvis, and was soon born alive. No hæmorrhage occurred.

The death-rate of mothers is much lower in this series of cases, not amounting to one per cent., while in the former it was two per cent. The causes of death were as follows:—

1st. Primipara.—Taken with convulsions during the second stage of the labour, and died eighteen hours after the birth of the child.

2nd. Multipara.—This patient was in a low state of health for a long time previous to her confinement, suffering from rheumatism which attacked the uterus ten days before labour; peritonitis set in immediately after the labour, and she died on the third day.

3rd. Multipara.—Premature labour at beginning of seventh month of pregnancy; labour came on in the third week of typhoid (enteric) fever, and she died a few hours after the birth of the child.

4th. Multipara.—Premature labour at end of seventh month of pregnancy; labour came on during the course of acute dysentery; died second day after the birth of the child.

5th. Multipara.—Premature labour at end of sixth month of pregnancy. The patient was in an advanced stage of Bright's disease of the kidneys; she died on the third day comatose, but did not have any convulsions.

6th. Multipara.—Premature labour during seventh month of pregnancy; was suffering at the time from acute double pneumonia.

7th. Multipara.—At full time; died from peritonitis on fourth day after craniotomy; she had been more than 40 hours in labour before I saw her; I endeavoured to deliver with long forceps, but failed; the upper brim of the pelvis was contracted in the antero-posterior diameter by an enchondromatous tumour on the sacrum. I then delivered the child by craniotomy. I think that if I had seen her earlier, and operated sooner, her life might have been saved.

The causes of death among the children are shown in the following table.

TABLE VI.

Causes of death.	Male.	Female.	Total.
Premature	13	7	20
Placenta prævia	3	—	3
Version	4	4	8
Craniotomy	1	—	1
Hydrops Amnii	1	1	2
Atelectasis pulmonum	—	1	1
Hydrocephalus	1	—	1
Imperforate anus	1	—	1
Hæmorrhage from navel	1	—	1
Anencephalous	1	—	1
Totals	26	13	39

The death rate of children in the first series was 4·5 per cent., but amongst them premature cases are not included. In the present series, including 36 premature cases with 20 stillborn children, the death rate is 6·6 per cent., but excluding the premature cases the death rate is found to be 3·3 per cent.

The two series of cases, therefore, taken together, give a mean death rate of mothers of 1·5 per cent. Of forceps cases 4·2 per cent., and of version 3·4 per cent.

Among the children, three were born with imperforate anus. In two there was a membrane occluding the anus, which was easily broken away. In the third case, which died, no rectum could be found in the pelvis. In the case of hæmorrhage from the umbilicus, I tried every means I could think of to arrest it. I tied the cord three times, each time nearer to the abdomen, and used styptics, amongst others Styptic Colloid, but without effect. I then passed a needle through the navel, catching the skin on each side, and brought a ligature in the figure of 8 round it, but shortly after, the bleeding began again. I then passed a curved needle through the skin, under the first

needle, across the umbilicus, and out through the skin again, and tied it across in a figure of 8, and then put a circular ligature round the two needles, but hæmorrhage came on again in about an hour, and the child died. The child when born appeared strong and healthy.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GOVERNMENT HOSPITAL, KANDY, CEYLON.

TWO CASES OF HERNIOTOMY, WITH OPERATION FOR RADICAL CURE.

By JOHN ATTYGALLE, M.D., M.R.C.S. Eng.,
Medical Officer in Charge.

Case I.

Stephen Appoo, a Sinhalese carpenter, aged about 35 years, was brought into the Government Hospital, Kandy, on the evening of the 8th March, 1884, complaining of excruciating pain in the left inguinal region, and nausea; he was very restless, skin clammy, countenance anxious, and he was also said to have vomited some "dark stuff" several times.

On examination, a large hernial tumour was found in the left groin, it was very hard and painful to the touch. From the enquiries made, it was elicited that the man had been suffering from reducible hernia for the last ten or twelve years, and about six months ago he suffered almost in the same manner as now. On that occasion, too, he was brought to the hospital, and I then reduced the hernia by taxis, and recommended him to wear a truss, which he did, but this afternoon whilst it was taken off that he might have a bath, the bowel came down, and would not go back. By the application of ice, and under the influence of chloroform every effort was made to reduce the hernia by taxis, but without success, and finding the man's condition getting worse and worse every moment, I decided upon performing herniotomy without any further delay, and did so at once with the assistance of my House-Surgeon, Mr. Chinniah.

On exposing the sac, a slight constriction was noticed opposite the external ring, which was pinched up and divided on a director, and an attempt was made again to reduce the hernia by manipulation; this, however, failed, and as a *dernier resort* the sac was opened. On passing the finger up the inguinal canal, a well-marked constriction was felt, occupying more than two-thirds of the internal ring. It was divided in the usual way with a herniotome, and the bowel was carefully pushed back into the abdominal cavity. This, however, was attended with some difficulty, and necessitated considerable handling of the bowel, because that portion which had descended into the scrotum would not move up whilst *in situ*, and had to be taken out of the wound before it followed the upper portion. The edges of the wound were brought together by means of silver wires, which were so applied as to pass through the sac, and covered over with dry lint. A grain of opium was ordered to be given to the patient every fourth hour.

March 9th, temperature 100·4°, slept pretty well. Abdomen slightly puffed up, but the patient does not complain of any pain.

Diet: Milk and Conjee, bread soaked in milk and chicken-broth.

March 10th.—Temperature 98·8° in the morning, 100·8° in the evening. No discharge from the wound. Bowels confined. Continue opium pills twice a day.

March 11th.—Doing well. Dressing changed for the first time, a slight discharge of thick pus on pressure. Abdomen somewhat puffy. A cathartic enema was ordered.

March 12th.—Bowels moved freely by the enema. Temperature was normal in the morning, but rose to 101° in the afternoon. Pills to be continued, with gr. ii. of Quiniæ Sulph.

March 13–16th.—Has been progressing satisfactorily during these days. Bowels were regular, but the motion this morning was rather loose and offensive. There is a slight discharge from the wound.

March 16th.—Morning to 12 noon. Has had six motions this morning, very offensive, and containing much mucus tinged with blood, and also lumps of undigested milk. Ol. Ricini ℥ i., to be taken immediately.

March 16th, 6 p.m.—Temperature 103·4°, pulse 110. Bowels moved several times after the oil. Pulv. Doveri gr. x., at bed-time.

March 17th.—Temperature 99·4° Had two motions during night, rather scanty and containing both mucus and blood. Wound doing well. Pulv. Doveri gr. v., Bismuth. subnitrat. gr. v., Pulv. Opii gr. i., Ft. pulv. i. every four hours.

March 17th, 6 p.m.—Bowels not moved since morning. Temperature 98.4°. Omit powders. Liq. Morph. Hydrochl. ♏ xxx. at bed-time.

March 18th.—Bowels acted once this morning naturally. Temperature normal. Little or no discharge from the wound.

March 28th.—Wound quite healed; the parts are much thickened, and the inguinal canal seems effectually obliterated; there is not the slightest sign of the bowel coming down.

April 8th.—The patient is quite well, and was discharged from hospital this morning.

Case II.

Singho Appoo, a Sinhalese man, aged about 35 years, was brought in on March 20th, 1884, with symptoms of strangulated hernia, and he stated that he had been suffering from reducible hernia of the right side for the last ten years, and a few years ago Dr. Anthonisz, of Galle, performed an operation (apparently Wood's) for its radical cure. The operation proved unsuccessful, and he had been wearing a truss ever since; and this morning when it was taken off to attend to a call of nature, the bowel came down and could not be put back. He had been suffering much, and complained of severe pain about the right inguinal region; the hernial tumour was very large, the surface of the skin was bedewed with perspiration; he was also said to have been vomiting several times, and all the symptoms showed intestinal obstruction unmistakably.

Taxis was applied under the influence of chloroform, but without success; and as nearly twelve hours had already elapsed since the bowel got strangulated, and the man's condition was getting worse rapidly, herniotomy was performed at once. The greater portion of the soft tissues in front of the sac were divided by transfixion with a bistoury. On exposing the sac, a marked constriction was felt a little below the internal ring, and no sooner it was divided with a herniotome, guided by the finger, than the bowel receded quickly into the abdominal cavity. The edges of the wound were brought together and dressed in the same manner as in the first case, and a grain of opium was ordered to be given to the patient thrice a-day.

March 29th.—Temperature 100°. Complains of some pain in abdomen on the right side above the seat of the wound.

March 30th.—Doing well. Bowels not moved. Temperature 100°. No discharge from the wound.

March 31st.—Temperature 99·4°. No pain in abdomen. Dressing removed for the first time, and the greater portion of the wound united by first intention. A cathartic enema was ordered.

April 1st.—Temperature normal. Bowels did not act after the enema. Omit pills, and a dose of castor oil to be given at once.

April 2nd.—Bowels acted freely after the oil. Wound nearly healed.

April 10th.—The patient is quite well and was discharged from hospital this morning. Bowel has not come down since the operation.

Remarks.—The two cases of strangulated hernia reported above are interesting, as showing in particular that even without the adoption of antiseptics, precautions so much in vogue nowadays, herniotomy is by no means so dangerous an operation as was at one time believed; and the great secret for its success lies in its being undertaken as early as possible, and before any injury has resulted to the bowels from prolonged strangulation. So far as I could judge from the appearances of the parts in both the patients after the wounds healed, the operation was not only useful in saving their lives for the time being, but also of effecting a radical cure of their complaints as well; and I think it always desirable in cases of herniotomy to secure the occlusion of the sac, as was done in these, or by one of the different methods mentioned by Mr. McGill, of Leeds Infirmary.

The wound in both the cases was dressed with simple dry lint in the first instance, and no symptoms whatever of peritonitis showed themselves; and I attribute this satisfactory result in a great measure to the free administration of opium, which is, to my mind, the remedy *par excellence* in such cases. The beneficial effect of opium in guarding against peritonitis in wounds of the abdominal parietes was well marked in the following case, which occurred in my practice some time ago.

A Sinhalese lad, aged about 10 years, was gored by a buffalo, and was brought to the hospital with a penetrating wound in the abdomen, through which nearly the whole of the small intestines were protruding. The boy it would seem fell on a dusty road after receiving the injury, and some sand and pieces of leaves were attached to the coils of the intestines. These were carefully washed away with a weak solution of carbolic acid, and the bowel put back as gently as possible. The edges of the wound were brought together with silver wire, and dressed with a pad of dry lint. Opium was given freely, and the boy recovered without experiencing any untoward symptoms.

An Unusual Obstetrical Case.—Dr. C. P. Strong reports the confinement of a healthy primipara, aged 30, attended with the following complications: prolongation of gestation (upon apparently conclusive evidence) to 299 days at least; a large child; entire absence of liquor amnii; interstitial and subserous fibroids so large that, after birth, the fundus of the contracted uterus reached to two inches above the umbilicus; contracted pelvis (flattened pelvis of Schröder), combined with occipito-posterior presentation and non-rotation of the head. The child was turned with difficulty, and extracted in a moribund state. The mother subsequently suffered with labial hæmatoma, partial sloughing of the perinæum and vulva, traumatic cystitis, and a febrile temperature lasting for five weeks; but ultimately recovered under opium, ergot, and antiseptic douches. Three months after labour, the posterior wall and fundus uteri were still thickened and irregular, but the fibroids had apparently melted away.—*Boston Medical and Surgical Journal*, January 10th.

Medical Times and Gazette.

SATURDAY, MAY 31, 1884.

In the House of Lords, on Monday last, Lord Stratheden and Campbell brought in, and moved the first reading of, a Bill for Abating Smoke in the Metropolis. He dilated at some length on the evils arising from the nuisance, citing statistics to prove the existence of the evils referred to, spoke of the work done by the Society for preventing Smoke in the Metropolis, and explained that his Bill would enable local authorities, under the supervision of the Home Secretary, to make by-laws for the gradual abatement of smoke and its ultimate extinction by the introduction of new apparatus; and, by the repeal of a few words in the Sanitary Act, would empower them to proceed against exceptional and aggravated smoke from private dwelling-houses. Lord Mount-Temple, after observing that it is characteristic of the British public to grumble, and after they have had their grumble to often be content to let a grievance slumber, supported the Bill, which was then read a first time.

The large increase in the number of cases of small-pox in the Metropolis during the last four weeks, incited Dr. Cameron to question the President of the Local Government Board, on Friday last, as to the measures taken to secure the vaccination or re-vaccination of all persons exposed to infection. Sir Charles Dilke stated in reply, that "What is, or should be, done" on the occurrence of small-pox, is that the vaccination officer, with such assistance as the Guardians may give him, should make detailed visits to the houses in infected streets for the purpose of detecting any children who may not have been vaccinated, and of urging re-vaccination on adults and adolescents who have not already been re-vaccinated, and who are exposed to danger of small-pox infection. Special places for re-vaccination have, on such occasions, been frequently provided by Guardians of parishes, to meet the convenience of special classes of people; and Sir Charles added that these measures had repeatedly been carried out through a union with excellent results.

This is very well, so far as it goes; and it is well also to be assured that "the Local Government lose no opportunity of commending these measures to Guardians;" but it would be much better were there less of a permissive tone about all these arrangements for preventing the spread of small-pox. The Board have only the power of "commending" them; and Guardians may carry out the recommendations of the Board, or may ignore them, should apathy, ignorance, or short-sighted stinginess guide the majority of them. A like feebleness taints all the provisions made to meet outbreaks of small-pox. The Vaccination Acts contemplate, says Sir Charles Dilke, that when a District Medical Officer attends a case of small-pox he *may*—the italics are ours—at once vaccinate or re-vaccinate any of the inmates of the house, and be paid for so doing the fee that the public vaccinator would have been entitled

to had he done the work ; and this last-named official *may* or *might*, in such circumstances, re-vaccinate at other than the ordinary stations, due notice of his intention to do so being given, should he think it necessary. The Local Government Board were aware that in Glasgow the Medical Officer of Health personally sees to things being done, promptly offers, in circumstances of hazard, re-vaccination, and is willing and ready there and then to perform it ; but, said the President of the Board, though in exceptional cases the vaccination may be performed at once in England also, that is not a part of the general system on which English vaccination is regulated.

Dr. Cameron further enquired whether it would not be well to spend a few hundred pounds in getting Medical Officers of Health to undertake in London the work they do in Glasgow ; and so to test whether outbreaks of small-pox may not be as cheaply, speedily, and effectually controlled in the metropolis as they have repeatedly been in Glasgow. The reply made to this would have done credit to a Past Master in Art of "how not to do it." This part of the question raises, the President of the Board said, the point whether the vaccination arrangements should not in the metropolis be transferred, as was recommended by the Royal Commission on Hospitals, from boards of guardians to the sanitary authorities. But at the present moment, when material changes are proposed in the constitution of the metropolitan sanitary authorities, this question cannot well be determined, though it is a matter which must receive full consideration as soon as such changes have been made. The interpretation of this is, that a matter of great and urgent sanitary importance is to be deferred till the political measure for the reform of the municipal government of the metropolis has been carried ; and that legislators of even Sir Charles Dilke's intelligence, honesty, and force of character are still to be found, who will to party give what is meant for mankind.

The Report of the Committee upon the Public Prosecutor's Office, has been laid upon the table of the House of Commons, is passing through the press, and will be obtainable before the vote for the Office is taken in Supply.

The last meeting of the Clinical Society, held on Friday, May 23rd, was brought to an early conclusion by the unusual reticence of its members. Of four papers on various subjects, only one gave rise to any discussion. The operation of removal of stone from the kidney, and the relative advantages of cutting or tearing through the kidney substance, or of opening the pelvis of the kidney alone, formed the chief points at issue. Mr. W. Anderson in his paper on the subject advocated the latter procedure, and proposed for it the distinctive title of pyelo-lithotomy. This proposition was gently ridiculed by Mr. Henry Morris, who suggested that an incision of the renal calyx, for a like purpose, might be fitly entitled "calico-lithotomy." Renal lithotomy, however, as he further observed, is as yet in its infancy only, and no positive rules can be laid down with advantage. An interesting case of impaction of bone in the larynx was read by Dr. Frederick Taylor. The bone had become impacted through the efforts of the patient's wife to extract it from his larynx by means of a table-spoon, and after this somewhat severe endo-laryngeal treatment, it was thought advisable to remove it by incision through the crico-thyroid membrane, which was accordingly done by Mr. Golding-Bird.

In accordance with his notice given at the previous meeting, the President invited the opinion of the members present as to his proposition to hold an additional meeting for the purpose of finishing the six papers remaining on the list. The general opinion appeared to be on the whole unfavourable to the proposition, and it was negatived by a majority of votes. At the conclusion of the business, the President mentioned that the council had decided to recommend certain alterations in the procedure of the Society's meetings in the future. It was proposed to take the refreshments, tea and coffee, before the meetings instead of afterwards, the present custom being, in the opinion of the council, an unphysiological practice. More facilities were to be given for the exhibition of living specimens, of which there have been so large a number during the present session. Both of these propositions appeared to meet with general approval.

At the Royal Medical and Chirurgical Society on Tuesday last, Dr. Herman described some "composite" temperature charts of small-pox. They represented the average temperature of a number of patients in lieu of the usual individual patient. Such a method may give useful averages if sufficiently large numbers of individuals be employed ; but it can never supersede the more usual method of carefully recording the individual temperature in each case. Subsequently two papers were read on the surgical treatment of pus-secreting cavities in the lungs. The case recorded by Dr. Cayley and Mr. Gould was one of gangrene in association with pyæmic symptoms following an abscess in the mastoid process ; stinking pus, and a sequestrum of gangrenous lung were discharged through a drainage tube which was passed into the cavity. The child made an excellent recovery. Dr. Biss' case was of a more chronic nature, and one in which the diagnosis was less easy to establish. Believing that an abscess cavity existed in the base of the lung, with slight effusion into the adjacent pleura, and other remedies having failed, it was decided to drain the abscess, one or two minor explorations having been made without much success. Mr. Marshall incised the chest wall, and then pushed in a large trocar to a depth of four inches, when a cavity was reached from which whiffs of fœtid air were expelled, but not much pus. The patient finally died, and the autopsy revealed not a large abscess cavity, but a number of bronchiectatic cavities. An interesting discussion followed, a summary of which will be found in another column.

Every member of the profession whose interests stretch beyond the circle of his own daily work, will have heard with singular pleasure of the distinction which has been conferred on the President of the

General Medical Council. The position which Sir Henry Acland occupies in the profession is a peculiar one, demanding a combination of gifts and qualities rarely met with in the same individual, and it is very proper that the rank bestowed on him should be a peculiar and distinguished one. The honour of K.C.B. is very rarely given to civilian practitioners of medicine, Sir William Jenner being at present the only one who has been picked out for it. In some respects it is a higher, though perhaps not more coveted, distinction than the baronetcy that falls almost as a matter of course to successful Court physicians and surgeons. No one will deny that Sir Henry Acland has thoroughly earned his reward. For the last thirty years—ever since he published his elaborate memoir on the cholera at Oxford—he has put behind him more unpaid and ill-paid work than almost any of his brother practitioners, and in his chairs in Oxford Street and at Oxford he has done service to the profession which only those immediately around him have any idea of. His peculiar position has enabled him to be a sort of connecting link between the profession and Society. He has done his best to enlighten the upper classes as to the position and place of the physician in the State, and in doing so, like a clever interpreter, he has made his client appear in the best possible light. His most important teaching has been that culture and moral earnestness are not necessarily stripped off in the dissecting-room.

The first meeting of the Oxford Graduates' Medical Club took place on Thursday, the 22nd inst., in the form of a dinner, at Limmer's Hotel. Like most inaugural meetings, it was a distinct success, fifty out of the eighty-one, who so far form the club, being present. There was some difficulty at first in finding out the whereabouts of all the Oxford graduates who have devoted themselves to medicine; and the club-list will probably soon become somewhat longer; but if the wishes of many of the older Oxford men are carried out, and no change is made in the arrangements for medical students at that University, the club may congratulate itself that it will long maintain the character it has started with, of being small and select. The sister club is of course much larger, owing to the greater facilities at Cambridge for utilising time in medical study, and the consequently larger number of general practitioners, of whom Oxford boasts but few. Dr. Fincham, President of the Club, was in the chair. His toast of the Medical Faculty at Oxford was warmly responded to by those holding all shades of opinion as to how this faculty might best be fostered. And Prof. Acland, in his eloquent reply, avoided all jarring notes, while he appealed to the proud satisfaction his fellow clubmen had in being Oxford medical graduates, and besought them, as it were, to assist in handing down the brilliant torch of Oxford medicine, undimmed, to succeeding generations at their *Alma Mater*. The evening continued and ended with the pleasurable talk of many long-parted acquaintances, unhindered by toasts or music.

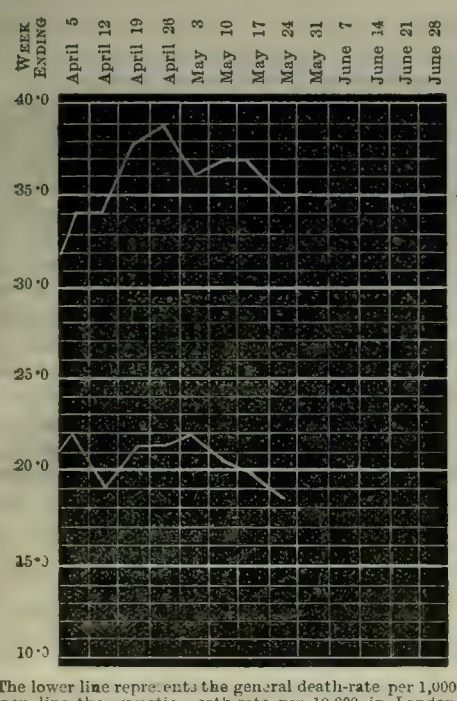
The choice of the electors to the new Cambridge chair of Pathology has fallen, by a very narrow majority, it is whispered, on Dr. C. S. Roy, the well known Superintendent of the Brown Institution. Once grant that the new professor's function should be research rather than teaching, and it will be readily admitted that a better candidate than Dr. Roy could hardly have been selected. He has had exceptional opportunities of training himself in the methods of physiological and pathological research, under Du Bois Reymond, Virchow, Recklinghausen, Cohnheim, and Michael Foster, and during the period that he has presided over the institution at Vauxhall, he has shown that he possesses in a high degree the imagination and inventiveness necessary to the successful investigator. The advocates of pure research may justly congratulate themselves on the fact that the election of Dr. Roy to the Cambridge chair has added another to the few endowed appointments open to investigators in this country. The Committee of the London University Senate who govern the Brown Institution will find it difficult to fill Dr. Roy's place, but it will be some consolation to them to think that they have in such quick succession supplied professors to the three chief teaching universities in the United Kingdom. There can be no doubt as to the success of the Brown Institution as an educational establishment.

The Council of the Royal College of Surgeons has just announced the following as the subject for the Jacksonian Prize for the ensuing year, viz.:—"The Diagnosis and Treatment of such Affections of the Kidney as are amenable to direct surgical interference." For the present year the subject is "The Surgical Treatment of Uterine Tumours, both Innocent and Malignant." The money value of this prize is the amount of the dividend, between 12*l.* and 13*l.*, received from the Trust. The College-triennial prize consists of the John Hunter Medal, executed in gold, to the value of 50 guineas, or at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of 50*l.* The subject for it is "The nature of Inhibitory Action in the Animal Body, to be elucidated by original research." The essays for the Jacksonian Prize for the present year must be delivered at the College on or before the 31st of December next.

On Wednesday week, at 4 p.m., Sir Henry Thompson will commence, in the theatre of the College of Surgeons, a course of six lectures on Some Important Points in connexion with the Surgery of the Urinary Organs. The following synopsis of the course has been published:—Lecture I. Wednesday, June 11th.—Introductory.—On the treatment of Stricture of the Uretha by internal Urethrotomy. Lecture II. Friday, June 13th.—On the diagnosis of Urinary Diseases.—Digital exploration of the Bladder. Lecture III. Monday, June 16th.—On Tumours of the Bladder: their nature, diagnosis, and treatment. Lecture IV. Wednesday, June 18th.—Impaired Vesical function: its various forms and consequences. Lecture V. Friday, June 20th.—The progress of Operative Surgery for Stone during the present century; with the most recent improvements in Lithotrity, and their results. Lecture VI. Monday, June 23rd.—The results obtained by

Lithotomy and Lithotrity in Great Britain during the present century; with an analysis of more than 800 cases by the author, presented therewith.

The general death-rate for London having in various weeks of the present year made unsuccessful attempts to get below 19·0 per 1,000, has at length succeeded. Last week the return was only 18·5 per 1,000, although the zymotic death-rate still remained unsatisfactorily near the top of our chart, and the number of zymotic deaths was 33 above the ten years' average. The deaths from diseases of the respiratory organs, on the other hand, were 27 below the average, and fewer than they had been in any previous week of the year. Of the



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the first eight weeks of the present quarter.

zymotic diseases, small-pox is still increasing in prevalence though not in fatality. Seventeen deaths from the disease were registered during the week, as compared with 30 in the preceding week, but 232 new cases were admitted into hospital as against 112 in the previous return. The deaths from measles and whooping-cough numbered respectively 81 and 92, and taken together were more than 50 above the average. There was a considerable increase in the number of deaths from diphtheria and diarrhœa.

The Registrar-General for Ireland's provisional report for the year 1883 has just been issued, and it may be worth while briefly contrasting its data with the corresponding returns for England which we published some weeks back. In England and Wales the birth-rate has declined during the last eleven years from 35·4 per 1,000 in 1873, to 33·2 in 1883. In Ireland during the same period, it has fallen from 27·1 to 23·6. In England and Wales during the same eleven years the death-rate has ranged between 22·7 and 18·9, reaching the latter figure in 1881; last year it was 19·5. In Ireland the range has been from 19·8 in 1880 to 17·3 in 1874 and 1876; last year it was 19·2. In England, last year's death-rate was 1·3 below, whereas in Ireland it was 1·0 above the mean of the eleven years. In Ireland the mortality of infants under one year in 1883 was considerably less than in England, the figures being respectively 99·6 and 137 per 1,000 births. In England during last year, the zymotic death-rate was 2·20 per 1,000; in Ireland it was only 1·64. In respect to all the zymotic diseases, except the various forms of fever, Ireland showed a marked superiority to England. It is satisfactory, as pointing to the increase in diagnostic skill, to note that within the last four years the deaths registered in Ireland as due to simple continued and ill-defined fever, have fallen from an average of over 1,000 to less than 400.

It may be remembered by some of your readers, writes our Liverpool correspondent, that the old Lying-in Hospital, Myrtle Street, Liverpool, had to be abandoned about two years ago, on account of the prevalence amongst its patients of erysipelas and puerperal fever. Severe epidemics of both diseases appeared in it again and again, and it was periodically being shut up and re-opened. Medical Committees of Inspection of the highest local standing were appointed at different times to examine and report upon the condition of the hospital, and each committee made recommendations which failed to reach the seat of the evil. The hospital was in a good situation, on a good foundation, and afforded by its elevated position every facility for good drainage. It was in a healthy locality, and its Staff was always composed of excellent men. Through its unsatisfactoriness, dissatisfaction spread amongst its supporters, estrangements took place between the Staff and the Committee, and the hospital was finally sold to the authorities of the Cancer Hospital. Under the new *régime*, and amongst the new class of patients erysipelas once more appeared, and Dr. Taylor, Medical Officer of Health, was again called in. He failed to detect any definite fault, and as a *dernier resort*, threw a quantity of chloride of lime into the main sewer. To the astonishment of the Staff, the hospital now became saturated with the easily-detected fumes of chlorine gas, thus proving undoubtedly a defect in drainage. The sewers were opened up, when it was found that, not only the hospital drain, but the sewer into which it opened sloped upwards *from* the hospital. These drains were therefore always stagnant, only the overflow passing over the hill.

In such a situation as that in which the hospital was built, it seems almost a matter of criminal carelessness or ignorance on the part of those responsible for this defective construction, to have made the sewers in the way they did. They appear to have actually gone out of their way to make them wrong. A long list of deaths may, at any rate, be ascribed to the error; and nothing can compensate the surgeons of the hospital for the worry and anxiety of years, involved in the constant struggle against the unseen foe, which they were told again and again by their architectural advisers did not exist. Ventilation, cleanliness, isola-

tion, and repeated evacuations were tried in vain, till at last they were compelled to beat a retreat. The capacity of the Staff was discredited, and every one connected with the place was disgusted and discouraged. Too much publicity cannot be given to the facts of this case, and it should teach medical men to open up the drains, in the face of engineering assurances that they are all right, if repeated outbreaks of preventible diseases lead them to suspect the invasion of sewer gas. The drainage of a hospital should always be before the Medical Staff by means of accurate drawings, so that they may at once look out for a leakage on the occurrence of any unusual phenomena in their patients. Since the alteration of the sewers in the case in point, erysipelas has disappeared from the hospital. A similar experience occurred in connection with one of our best built metropolitan hospitals only a few years ago ; and the rule in such cases should be, not to trust the assurances of architects, who are often utterly unskilled in sanitary science, but to at once put the matter into the hands of a specialist in drains.

Considering the numerous reports which he has furnished recently to the Local Government Board, on the general sanitary condition of the Tynemouth Registration District, it might have been imagined that Dr. Barry had exhausted the subject. So far from this being the case, however, he has considered it necessary to send in a report which is full of suggestions for improving the health of this great mining district. Round most of the large coal-pits there, sets of houses have, little by little, grown up, which are generically termed "colliery villages," and to these, in a great measure, is to be traced the prevalence of infectious diseases in the locality, a prevalence which will be understood, when, as Dr. Barry shows, scarlet fever has prevailed epidemically with great regularity at intervals of from five to six years, for the last seven and twenty years, with a death-roll of nearly 4,000 souls.

The conditions which have tended specially to influence the spread of infectious disease in these colliery villages, apart from the habits of the people, are, Dr. Barry thinks : the arrangement of the houses in long rows without cross-openings ; the distribution of the water to stand-pipes common to large numbers of houses, largely resorted to by dwellers in healthy and infected dwellings indiscriminately ; the drainage system of an open channel common to all the houses in a row ; the storing of filth and excrement of two or more families in one common receptacle, never properly emptied ; the peculiar danger arising in those villages supplied with water pumped from the pit, on account of the temporary nature of these supplies, and the possibility of the inhabitants being driven to use water from polluted sources ; and lastly, the utter absence of any means in these small houses for isolation, whilst in many of the oldest an additional danger is met with in the defective nature of the party-walls which permit of atmospheric communication between adjoining houses.

It is only right, however, to point out, Dr. Barry adds, that colliery villages are usually well situated, that there is ample air space around the houses, that there is rarely or never any connection between the interior of the houses and the sewers, and that the privies, as a rule, are at a considerable distance from the dwellings. Further, personal and domestic cleanliness is greater amongst the mining population than in almost any other class of working people. The women not being employed in the pits, and not having, as in manufacturing towns, any share in providing for the family, have ample time at their disposal, and as the house-work is easily done, they congregrate wherever there is sickness, accompanied by the younger children, and thus promote the spread of infectious disease.

Whatever opinions may be entertained as to the therapeutic value of koumiss and the relative merits of the different kinds, the advantages presented by asses' milk over that of cows', in certain conditions of the digestive organs, have long been recognised. The explanation is to be found, not in the relative proportions of the casein and albumen, lactose and fat, but in the fact that the casein of the milk of equine animals exists in a different form from that in which it does in the milk of the ruminants, being but imperfectly, if at all, coagulated by acids—a property which is possessed also by the casein of human milk, and which has led M. Housson and others to regard it rather as another form of milk albumen. As asses' milk, which has been proved, in the Foundling Hospital at Paris, to be greatly superior on this account to cows' milk in the nutrition of infants under three or four months, is not always to be had, the introduction into the market of a condensed mares' milk will be felt as a boon by many. The manufacturers possess a stud and factory near Orenburg, on the borders of the steppes of South-Eastern Russia, and made their first experiments in the summer of 1882 ; but last year may be considered the first of regular work, and the article is greatly superior to that turned out in 1882. The contents of each tin weigh ten ounces, are very thick, of a pure white colour, and pure honey-like taste. The analyses of Dr. Vieth confirm the statements of the manufacturers, that not more than three per cent. of cane sugar is added, and that the milk has been condensed to one-eighth of its volume, *i.e.*, to one-sixth of its weight. The composition of the milk diluted in the proportion indicated, making allowance for the added sugar, closely corresponds to the few analyses we have of the mares' milk of the steppes ; the small amount of added sugar is certainly no fault, while the ready digestibility of the casein will probably be found of great value in the artificial feeding of delicate infants.

Mr. Frederick Charles Heidenstam, the Chief Medical Officer of the Government of Cyprus, has been gazetted a C.B.

At the first meeting of the Medical Jurisprudence Society of Philadelphia, Dr. Reese read a paper on "Medical Experts." After pointing out the unsatisfactory state that at present obtains, by which any one can be put into the witness-box and call himself an

expert, his evidence being received as of equal value with that of men who have made a special study of the subject, he suggested that the only remedy for this evil is the appointment of state medical experts. Such a one would have to be a well-educated practical physician, thoroughly up in all the details of medical jurisprudence. He would have to sit with the judges during the trial, and enlighten the court and the jury on the technical points in the case, he would make the analyses in cases of poisoning, and being retained by neither side his evidence would be without bias. The salary should be liberal, as the holder of such a post would of necessity be precluded from private practice, and he should be elected by the judges of the Supreme Court of the State.

There can be no sort of doubt in the minds of most people that the present system of allowing anyone, no matter how slight an experience he may have, to be put forward to give skilled evidence is objectionable, and often very unfair, and that some reform is urgently needed. But will the plan as sketched out by Dr. Reese meet all the requirements of the case? This seems to us open to doubt. What is wanted in a scientific witness is that he should be a man of experience, not in medico-legal matters only, but in general medicine and surgery. And this is just the difficulty that has not hitherto been bridged over. It would be easy enough to get able and well-educated young men to accept such a post, but they would lack the one qualification, which alone would enable them to give a reliable prognosis, viz., experience. And it does not seem likely that such a salary would be offered as would induce anyone who had already gained that experience, to throw up his private practice and accept the post.

The Minister of Public Instruction at Berlin has resolved upon the foundation of a professorship of hygiene in the Berlin University; and to this there will be attached a Hygienic Institute, under the direction of Geheimrath Robert Koch. No such institute has been founded hitherto in any of the Prussian universities.

So many evil influences have from time to time been declared to be at work in the production of endemic cretinism, that it almost becomes a matter for marvel how any of the dwellers in the affected districts can escape the disease. Geological and meteorological conditions of every kind have in turn been reckoned among the predisposing, if not the exciting, causes of the malady, and by some writers even a directly infectious character has been attributed to it. It is not, therefore, a matter of surprise to find, by the report of a meeting of a Health Society in Vienna, that cretinism is on the increase in the mountainous districts of Styria, Carinthia, and Istria. Its distribution appears to follow the primitive formations and the streams which have their rise in them; it occurs but little on the chalky soils, and is most prevalent in the valleys. A definite opinion, expressed by Professor Billroth at the same meeting, that the disease is essentially hereditary, the tendency being fostered by the frequent intermarriage of families, was fully borne out by the experience of other observers. The introduction of a new race of inhabitants, as in the construction of great works such as the St. Gothard Railway, has always been followed by a distinct diminution in the number of cretins, although the increase of traffic and the more civilised mode of life may also have played a prominent part in the production of a more perfectly organised race of beings.

Dr. Hans Virchow, the son of Prof. Virchow, who has hitherto been working as privat-docens, at Würzberg, has been summoned to Berlin in order to assume the direction of the histological course under Geheimrath Prof. Waldeyer.

In the course of the intermittent warfare which has been waged on paper between the anti-vivisectors and their opponents, the position of the latter has hitherto been defended, almost entirely, by members of the medical profession, and it is obvious that such is, for the most part, likely to remain the case, since—while it is easy enough for even a superficial humanity to find objections to the practice—a true and impartial appreciation of the real and relative value of the arguments for and against vivisection is possible only to those who have devoted special training and a wide field of observation to the consideration of the subject. In other words, it is the physiologist *and* the practitioner who are, jointly, best qualified to speak with authority on the subject. But although to but few, if any, of those outside the profession are given the opportunities of such mingled research and observation as would entitle them to equal rank as original authorities, yet every layman of intelligence and industry may—if he will but take the necessary trouble—learn to appreciate the facts and rightly to use the arguments which they employ. Mr. Girdlestone, in his pamphlet on Vivisection,[1] has done good service to the cause he champions. If he cannot speak as a working physiologist or as a practising physician, though his deductions are sometimes hasty, and his conclusions—as must be the case in a hurried survey of so wide a field—sometimes incomplete, he has assimilated the great arguments for his creed, and can reproduce them in forcible and trenchant English. Such a work cannot, perhaps, be expected to make much impression on the leaders of the anti-vivisection movement, for we own to a realistic acquiescence in the truth of the sentiment which the author quotes from Professor Max Muller, "The older I grow, the more I feel convinced that nothing vexes people and hardens them in their unbelief and in their dogged resistance to reforms so much as undeniable facts and unanswerable arguments;" but it may influence some of those who are too often led by appeals to mere sentiment, or so-called feeling. In any case, it is cheering to find a lay writer on this subject who has not only the courage to think for himself, but also the honesty and the industry to discover what it is that he thinks, and why he thinks it.

[1] "Vivisection: In its Scientific, Religious, and Moral Aspects." By E. D. Girdlestone, B.A. London: Simpkin, Marshall, and Co. Clifton: J. Baker and Son. 1884.

***

The thirty-fifth meeting of the American Medical Association, which was held at Washington, from May 6th to May 9th, under the presidency of Dr. Austin Flint, Senr. seems to have been very successful as regards the numbers present and the general tone prevailing. The thorny subject of the "New Code" was somewhat softened down under the conciliatory management of so genial and popular a president, who admitted that the Code of the Association wanted some expansion as to the range of permissible consultations, although he did not show very clearly how this was to be brought about. In the meantime, at the late meeting the matter was "shunted," for it seems as far as ever from being settled—the Association at present requiring a pledge of the unaltered Code to be taken as a condition of membership. Judging from the reports which appear in the American journals, the scientific work done at the various sections does not seem of a very high character; and the "Journal" which has been substituted for the "Transactions" evidently has a hard struggle for life, amidst the severe competition which the greatly improved condition of the weekly Medical Press in the United States subjects it to. The delegates to the International Medical Congress at Copenhagen are to be the bearers of an invitation to hold the next international meeting at Washington in 1887.

The benefit which many cases of phthisis derive from a residence during the winter months in the elevated plateaus of the Alps is so fully recognised that physicians would do well to acquaint themselves with the special features of the several localities, to one or other of which they may send their patients. We have before us elaborate series of meteorological observations made at Maloja, and recently communicated to the Meteorological Society by Dr. Tucker Wise, who believes that this station presents several advantages over those of Davos and St. Moritz, and is even preferable to Wiesen, especially in the closer proximity of glaciers, which neutralise the unpleasant influence of the föhn, or south and south-west winds, more effectually than elsewhere. Like Wiesen, it is exempt from the mists to which Davos is most subject, and it enjoys a greater number of hours of sunshine than any station in the Engadine. The observations of a single season, which may have been an exceptional one, are insufficient for forming a judgment of any place, but we may remark that the mean temperature of the four months, November, 1883, to February, 1884, was 25° F., and the extremes 45°, on December 26th, and 7·5° on February 19th; that is between the hours of 9 a.m. and 3 p.m., during which patients are accustomed to enjoy the air. The mean solar radiation was 104°, having been lowest during December. Rain or snow fell on 24 days. The barometer ranged between 601 and 623 mm., and the mean weight of vapour was 1·2 grains in a cubic foot, which for the mean temperature of 45° F. would equal about 33 per cent. of saturation.

On Thursday the library of the Royal College of Physicians was the scene of such a solemn meeting of Fellows as has hardly been held within living memory. It has been an open secret during the past week that the list of Members proposed by the Council of the College for election to the Fellowship has met with very widespread disapproval. There were names on it, it is said, the sight of which gave a shock to many of the Fellows, and names omitted which everyone had expected to see on it. Some of these names, it is hinted, were omitted as a matter of principle, and this naturally gave rise to protest as a matter of principle. This, combined with other sources of dissatisfaction, seems to have lent such strength to the opposition that the list of Fellows was referred back to the Council by a tremendous majority. Such a thing has not happened since 1859, and though the vote is not meant to be a direct censure on the Council, it is a sharp reminder to it that the free action usually granted to it is granted as a privilege and not as a right. We welcome this rebellion of the Fellows as a most healthy sign. That such a vote can have been given shows how much more popularly constituted is the College of Physicians than the College of Surgeons.

ATHENS *versus* BABYLON.

If any authoritative counterblast were needed to the uncompromising attack on the University system of the modern Athens, which we published with some hesitation last week, it has been furnished by Professor Ray Lankester, in his powerful article in the *Pall Mall Gazette*, of the 22nd instant, entitled "A University for London;" and we would rather refer our readers to that writer's able advocacy of the Edinburgh system, than crowd our columns with the many indignant, but in our opinion unneeded, protests against the assertions of "Academicus," which we have received. Professor Lankester is anxious that the modern Babylon should have a university, not a mere examining board, but a real university, such as the modern Athens has—a university "on the well-tried and established models of Germany and Scotland, with its faculty of arts and science, its faculty of law, and its faculty of medicine, each faculty numbering some twenty professors, and the combined sixty professors forming the senate, in which the absolute and sole governing authority of the university is vested, subject to constitutional limitations, and a ministerial veto." "Thus arranged," continues Professor Lankester, "the governing body of the university is keenly sensitive to all conditions which may tend to cause fluctuations in its reputation for excellence and practical utility, and consequently in the number of its pupils. Such a body may be trusted to arrange fair and sufficient examination tests for its degree, to give suitable teaching to its students as a preparation for those tests, and to secure the services of men as colleagues in the professoriate who will by force of their proved capacity and wide reputation lead to the increase of the numbers of students, and consequently of students' fees, under its control." The scheme looks very well on paper, but for our own part we must confess that we distrust Professor Lankester's ideal picture almost as much as we distrust the real one, which "Academicus" painted with such a free brush in these columns last week. The very faults which the latter condemned, and which we are inclined to think do exist, at any rate in the modified form of tendencies, would have

been impossible but for the system which we are implored to import into London. A university with a fair proportion of "outsiders" on its senate, would never have exposed itself to even a whispered accusation of mercenariness.

But the suggestion of a *real* university in London has to be regarded from other points of view. Is it wanted, is it practicable, is it desirable? Dealing with the suggestion solely from the medical point of view, we do not think that any of these adjectives can be applied to it. A considerable part of the function of a university is already undertaken in London by the Colleges of Physicians and Surgeons, which, whatever their shortcomings, no one would wish to see displaced by a brand new university "on the well-tried and established models of Germany and Scotland." The Colleges are every day coming to be more and more regarded as the true foster-mothers of the higher medicine, and the higher surgery; the upper ranks of the profession will always, of necessity, become associated with them, and we do not suppose that even Professor Lankester would suggest founding a university solely for general practitioners. But they are only examining boards! Well, we do not know that they are for that any the less interested in the number of pupils at the London Medical Schools. Certainly no one will contend that the teaching given at the best metropolitan hospitals, in response to the demands of the Colleges, is inferior to the teaching given in the crowded lecture-rooms and hospital wards at Edinburgh. There is no doubt a deplorable degree of wanton waste in medical teaching in London, which needs firm and combined action to overcome, but we doubt whether a new university would be able to exert the required pressure. The number of medical students is much too large and the hospitals far too scattered to be gathered up under the wings of a single *Alma Mater*. At least three or four schools of primary medical instruction are needed, with free competition between the clinical teachers of the different hospitals, to make medical teaching in London at once thorough and economical without being unmanageable. If, on the other hand, it is proposed to found a university for the *élite* of the students—if it is proposed to have its degrees earned and not bought—if, further, it is proposed to teach these students apart from the duller-brained remainder, then we submit that no more injurious scheme could have been devised. It would mean reducing the students at the non-university schools to a dull level of mediocrity, relieved only by the few scattered Cambridge graduates. It would mean taking from them all the incentive and example afforded by mixing with men of greater talents and application than themselves, and we should have, as the result, a dozen schools of dunces, and one of prigs.

After all, has not the whole discussion arisen out of servility to a word? Is it necessary that a university should always imply the combination of the teaching and the degree-giving functions? Are we not to be allowed to modify its connotation with the changes and the specialisations that time brings about, just as we have modified and restricted the meaning of the word "physician"? We think it would be difficult to show that the University of London—a mere examining board—has had less influence on the teaching of medicine than the University of Edinburgh with all its array of professors. The influence of the latter has been more visible perhaps because more concentrated, but the former has raised the standard of medical education not only in all the metropolitan and provincial schools of medicine, but at the University of Cambridge and even at Edinburgh itself. For our own part, we would willingly see the University of London taking some share in medical teaching—not, however, as replacing or directly controlling the function of the hospital schools, but rather as supplementing it. We would gladly see it provided with working laboratories and a staff of professors whose aim would be to give that advanced medical instruction which is now so generally neglected. Courses of lectures on medicine, surgery, pathology, medical chemistry, insanity, hygiene, epidemiology, &c., to be attended by graduates before taking their M.D. degree, might be delivered with the greatest advantage to the extension of the higher medical training. By undertaking such a duty the University of London would supply a much more needed want than if it were to enter into the lists with the modern Athens, or seek to gain the fees and suffrages of College passmen.

A QUESTION OF PRIVILEGE.

In the debate on the Army Estimates, many important matters affecting the future of the Army Medical Department were discussed, and on very many points the intentions of the War Minister were declared clearly enough. It was perfectly plain that he had made up his mind to strengthen the Department, to unite with it the Army Hospital Corps, to hand over to the doctors the command of their own hospitals, and to stand fast by unification. He ignored the traditions of the Horse Guards, to the extent even of abolishing the combatant command of the great prize, Netley; and he held out no hope of the resurrection of the old regimental system, when each surgeon was the friend, confidant, and factotum of his own particular corps, and of nobody else. But the Secretary for War broke down sadly when he had to face the privileges of the Household Cavalry, and their special arrangements for the treatment of their sick troopers in London. It takes a bold man to defy "Society," and not even Lord Hartington dared to defy "London Society," as illustrated by the Household Cavalry. It had been proposed to establish a grand Military Hospital in London, where medical officers of the Department might serve on their return from long service in the colonies, and be enabled to refresh their memories and perfect their skill, by visiting the great civil hospitals in London. The members of Lord Morley's Committee had highly approved of such a scheme. They said, "We are of opinion that the Medical Service of the Household Troops should be assimilated to that of the Army at large. The present organisation is injurious alike to individual officers and to the general service. To the officers, because it excludes them from the experience gained in foreign service, and consequently from advancement to the higher grades of their depart-

ment; to the service generally, because the monopoly of London appointments by the medical officers of the Guards, excludes the officers of the Medical Department generally from all chance of serving there, and thus gaining access to the medical schools and hospitals of the metropolis. We attach great importance to this point, for it is highly desirable that as many Army Surgeons as possible should, at some period of their career, have opportunities of visiting large civil hospitals, where the cases are of a far more serious and varied nature than those which usually come before them, and thus of keeping themselves informed of the progress of medical and surgical science." No doubt the Minister for War has studied this opinion, and, as a man of sense, he must have approved of every word; but what was he to do or to say when "the colonels" rose in their wrath and asserted privileges? No wonder he spoke of the hospital of the future in uncertain accents. The idea was good, but, he said, "it cannot be entertained until the question of Regimental Hospitals has been thoroughly disposed of; but that cannot be disposed of for some time to come." The medical arrangements of the Household Cavalry stand in the way! Here, indeed, is a tremendous puzzle to be solved.

The Service generally requires a London Military Hospital, but the Hospital cannot be built until the medical arrangements of the Household Troops are changed, and they cannot be changed until the great London hospital is built. Somebody must evidently give way, and for the present it is the Medical Department, the patients, and the public generally who have to suffer, that the privilege of the Guards may remain intact. Lord Morley's Committee would have made the Household Cavalry give way. They said, "The evidence which we have received proves conclusively that it is unadvisable that the Household Troops and the rest of the Army should be worked under different and to some extent independent systems." It may be that Lord Hartington is trying to find out the meaning of the words, "to some extent independent systems." It is a curious thing that nobody knows the relative position of a medical officer of the Household Cavalry to the head of the great Army Medical Department. Worse even than that, nobody understands the relative position of a surgeon in the Life Guards to his supposed superior, a Surgeon-General of the Medical Department, in time of war! There is some tradition, perhaps, and maybe some obsolete custom or privilege, which implies independence, but on reading the evidence given before Lord Morley's Committee it is perfectly clear that the Director-General himself is doubtful of his authority over the medical officers of the Household Cavalry, and that among these there exists a question as to the Director-General's power of appointment to the medical charge of the Household Cavalry, even during a campaign! It surely cannot be right that the Guards' "privilege" should enable a Surgeon of the Household Cavalry to recommend that the arrangement of the Army Medical Department should be interfered with for the benefit of his own particular corps. It cannot be maintained that "privilege" should give a "Guards'" medical officer the right to refuse compliance with the orders of his undoubted superior during a campaign, and no one would wish to see a Surgeon Major of the Household Cavalry permitted in future wars to occupy what one witness described as a *unique position* in the Egyptian expedition. Perhaps when the Secretary for War has had time to consider the relative position of the medical officers of the Household Troops, and the Army Medical Department, he may be able to draw up "a memorandum" which will abolish "unique" action in time of war, and also permit of the establishment of a Central Military Hospital in London where medical officers of the Guards may, without loss of dignity, serve under their superiors of the Army Medical Department, and yet retain their regimental position. If the regimental system was ever a necessity, it was undoubtedly so in the Guards. The habits and expenses of London life in Society cannot be shared by all doctors alike, and we should be sorry to see the Household Brigade made uncomfortable by having uncongenial men thrust upon them; but "privilege" seems to go too far when it extends to the prevention of the institution of a great Military Hospital in London.

CLINICAL PAPERS.

XI.—Cerebral Syphilis.

The extraordinary interest which has been developed with regard to diseases of the central nervous system during the past twenty years, has not only led to a very great increase in our knowledge of the physiology of the various regions of the brain, but has also directed attention to what in one sense may be regarded as of even greater importance, namely, the frequency with which syphilis occurs as the *fons et origo mali* in this class of disorder. Indeed, on glancing over the literature of the subject, it would appear that the effects of syphilis on the brain are both better understood and more generally recognised than on any of the other viscera. Gummata in the liver are, it is true, perfectly well known in the *post-mortem* room, but he who ventures to diagnose syphilitic phthisis from the history and physical signs alone must be prepared to find himself regarded as a man with a hobby. Of all the viscera in regard to which we are not able to use the sense of sight to aid us in diagnosis the brain is the only one, a given lesion of which we can, with reasonable certainty of being correct, ascribe to the effects of syphilis.

Syphilis may attack the brain substance itself, its membranes, or its arteries. This is not the place to enter upon a minute description of the pathological changes which take place in each instance; suffice it to say that in the arteries the change consists in a proliferation of cell elements beneath the endothelium, causing a bulging inwards and gradual obliteration of the lumen of the vessel, the final step being generally the formation of a thrombus owing to the great obstacle to the circulation at that point. In the meninges a fibroid change is common; it is not usually diffuse, and is often associated with gummata in the dura mater;

the pia mater may be affected alone, or there may be a diffuse meningo-encephalitis. In the brain itself syphilis gives rise to either gummata or sclerosis; the latter has its usual seat in the cortex, the former are most common at the base and in the central ganglia. The manifestations of syphilitic encephalopathy, as some of our Continental neighbours would say, appear most commonly from three to ten years after the primary infection, but they may be delayed till a much later period, or, on the other hand, they may come on within a few months of the original malady. To this latter class we shall not further allude, except to say that when the symptoms of an affection of the nerve centres appear thus early, the disease usually proves not very amenable to treatment. Hereditary syphilis, too, affects the nervous system, giving rise to meningitis, arteritis, and gummata, or sclerosis in the brain. Of these, contrary to what takes place in the acquired disease, sclerosis is more common than arteritis, and gummata may be considered as somewhat rare.

Headache is usually the first warning, the earliest manifestation of intra-cranial syphilis. Its prominent characters are that it is apparently causeless, lasting, and liable to exacerbations, especially at night. It may be diffused, but often appears to be localised; if percussion over the spot indicated increases the pain, the inference would be that there was a meningeal gumma beneath that spot. Some writers go so far as to regard a persistent severe headache with nocturnal exacerbations as pathognomonic. Amongst the symptoms which may be associated with headache and which are of value in diagnosis, are, transient attacks of giddiness, and temporary disturbances of the senses; in more severe cases the feeling of vertigo may become permanent. Aphasia, too, is a not very infrequent occurrence, whether transient or lasting; but the most important symptom at this stage is the condition which has been described as syphilitic coma, though, as pointed out by a recent writer, the condition is one of prolonged somnolence and mental obfuscation, and does not merit the name of coma. This state may last a month or more and is generally of bad augury, though complete recovery is by no means impossible. During it the patient takes little or no notice of what is going on around him, though he can be roused to answer questions; but if he recovers it is found that he has a much better knowledge of the events that have been taking place about him than would have been expected.

The motor phenomena associated with syphilis are very important, hemiplegia being the most common. When a moderately young man, who presents no other signs of disease about him, and who has not suffered from rheumatic fever, develops a hemiplegia preceded for a varying time by headache, and coming on without loss of consciousness, or convulsion, the presumption of a syphilitic arteritis would be so strong that one would be tempted to feel that if the patient denied having had syphilis the onus of proving that he had not ought to lie with him. Other motor paralyses might be present which would greatly facilitate diagnosis; certain of the cranial nerves, for instance, are very commonly affected. Paralysis of the third, fourth, or sixth nerves, or of some or more of them, is very common; indeed, a combination of several ocular paralyses would be almost proof of syphilis. Or the association of some ocular paralysis with a brachial or crural monoplegia, pointing as it would to a double lesion, would be strongly suggestive of syphilis. One character that all these motor paralyses have in common is that often they are transitory, changing almost from day to day. Sensory paralyses, though not unknown, seem to be by no means so frequent as motor, a fact for which an explanation is still wanting.

From the fact that meningo-encephalitis is a not uncommon form for the disease to assume, it will be readily understood that the symptoms may sometimes most closely simulate those of general paralysis of the insane, if indeed the true disease is not set up thereby; but the consideration of this aspect of our subject must be left for a future occasion.

As regards the so-called syphilitic epilepsy, there is nothing, either in the seizure itself or in the mode of onset, which will enable us to distinguish epilepsy due to syphilis from the ordinary form, but in the former the aura is more often absent, the attack is more likely to be unilateral, and the intervals are said to be less exempt from morbid disturbances than is the case in ordinary epilepsy. After a series of attacks it is not uncommon for hemiplegia to be established on the side most affected in the syphilitic variety. An epilepsy coming on after thirty years of age is more likely to be syphilitic than not. Π

REVIEWS AND NOTICES OF BOOKS.

Hay Fever, its Ætiology and Treatment; by MORELL MACKENZIE, M.D. Lond. London: J. and A. Churchill, 1884.—This is a condensed but very complete account of a most interesting pathological condition, the subject being treated with that conscientious thoroughness which distinguishes all Dr. Mackenzie's literary work. The essay is written on the scheme adopted in the author's well-known manual of "Diseases of the Throat." An exhaustive account of the bibliography of the disease is given, and its ætiology is discussed with fulness and fairness. The symptoms, diagnosis and prognosis are described in the light of the considerable experience the author has collected on the subject. The directions given as to treatment are rational and scientific, and should be consulted by every one who is called upon to prescribe for this intractable malady.

Medical Fashions in the Nineteenth Century; by EDWARD T. TIBBITS, M.D., Lond. London: H. K. Lewis, 1884. This is a readable little book and may have a beneficial effect on the minds of superstitious practitioners, but the sensible and educated physician will find in it no thoughts except those with which he is thoroughly familiar. The sceptical frame of mind is a very valuable one in a medical writer, and a thoughtful and suggestive book written from the sceptical standpoint, with full and accurate knowledge of the subject, would be a welcome addition to medical literature. But Dr. Tibbits, especially in dealing with the "battle of the bacilli" as he calls it, evinces that he has not taken the trouble to master his subject, or, if he has, he has shown singular perspicacity in attacking the weak points, and ignoring the strong ones in the theory which he opposes. His frame of mind is indeed one with which we entirely sympathize; but at the same time we cannot forget that the opposite quality of intellect, the sanguine and enthusiastic, is equally necessary to safe progress. In a world of sceptics, there would be no discoveries.

ABSTRACTS AND EXTRACTS.

OBSTETRICS AND GYNÆCOLOGY.

THE CAUSES OF THE SHAPE OF THE PELVIS.—A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains a paper by Dr. J. Veit, of Berlin, on the above interesting subject. The elucidation of the subject, from a mechanical point of view, is chiefly due to Litzmann in Germany, and Matthews Duncan in this country, whose method has been followed, in their able contributions to our knowledge, by Leopold and by Champneys. Litzmann's fundamental proposition is, that the shape of the pelvis depends upon the co-operation of four factors:—(1) The tendency of the bones to grow in a particular shape. (2) The weight of the body. (3) The resistance of the pelvic bones and cartilages. (4) The pressures and traction produced by the muscles attached to them. Taking as a starting point the pelvis of the new-born child, he seeks to explain the production out of it by the different forces named, of the various forms of deformed pelvis. His views obtained very wide acceptance, but lately they have been opposed, chiefly by Kehrer, Fehling, and Schliephake. The paper of Dr. Veit is devoted to examining some of the objections raised to Litzmann's views by these authors. One of their main arguments is based upon the so-called fœtal rachitic pelvis—a pelvis that is met with in the fœtus, therefore produced by forces acting in utero, and much resembling the rachitic pelvis of the adult. While the child is floating in the liquor animi, the weight of the trunk cannot possibly be operative in altering the shape of the pelvis, and thus if the rachitic pelvis can be produced in utero without the pressure of the body weight, it follows that this pressure cannot be an important factor in the production of this shape of pelvis in extra-uterine life. Dr. Veit points out that those pathologists, Virchow among them, who have investigated the morbid condition present in these fœtuses, are of opinion that the disease is not rickets. (As we are writing for English readers, we may mention that the subject was brought before the Pathological Society some time since by Dr. Thomas Barlow, who pointed out the differences between this disease, which is a cretinoid condition, and genuine rickets.) If, then, these pelves be not ricketty, inferences drawn from them as to the production of the ricketty pelvis fall to the ground. But further, Kehrer has described ricketty pelves in *children*, and these show the transition between the normal shape of the fœtal pelvis, and the adult ricketty pelvis that might have been expected if Litzmann's views were correct. The latter author has laid much stress, as might be expected, on the study of the normal fœtal pelvis. This branch of the subject has been well worked at by Fehling, who has advanced our knowledge of it by most careful measurements. Dr. Veit examines these, and adduces also measurements made by himself and by Dr. Carl Ruge. From these he shows that the sacral promontory, which in later life lies in the plane of the pelvic brim, in the fœtus is situated *above* the brim. He holds that allowance must be made for this difference before inferences can be drawn from the comparison of the fœtal and adult pelves. Dr. Veit draws another argument from the shape of the pelvis which accompanies congenital dislocation of the hip. When this deformity is met with in the adult, a characteristic shape of pelvis is associated with it; but in the fœtus, no such peculiarities in the pelvis have been met with, showing that the effect of this dislocation upon the pelvis must be produced subsequent to birth. Dr. Veit's general conclusions are the following: "The flat pelvis, rachitic or non-rachitic, of the adult, is not identical in its characters with the pelvis—either normal or so-called fœtal rachitic—of the fœtus. The pelvis of the adult differs essentially from that of the fœtus; and the change from the shape of the one to that of the other, can only be explained by forces acting in extra-uterine life. Pathological shapes of pelvis occur in utero, but they are essentially the result of general and local malformations, and stand in no genetic connection with similar shapes of pelvis occurring in the adult. Litzmann's explanation of the origin of pelvic deformities, by the pressure of the body weight, &c., is necessary for their comprehension; the other forces which have been invoked are either too indefinite in their effects, or their potency has been over-estimated.

THE "PELVIS JUSTO ÆQUALIBITER MAJOR."—A recent number of the *Archiv für Gynäkologie* contains a paper by Dohrn on the above subject. He has made a series of careful measurements, to determine whether this pelvis is really one enlarged in all its diameters, or whether there are not some points in which it differs from the normal pelvis. He finds that there are. At the brim, the oblique and transverse measurements are shorter in proportion to the conjugate than in the normal pelvis. In the cavity the antero-posterior diameter is relatively shorter and the transverse diameter relatively larger. At the outlet the transverse diameter is relatively diminished. The posterior superior iliac spines are relatively nearer, and the anterior superior iliac spines relatively more distant, than in the pelvis of normal shape; that is to say, the iliac bones look slightly more forwards. The sacrum also is proportionately narrower. Lastly, the angle which the plane of the true conjugate makes with the anterior wall of the pelvis is less than in the normal pelvis. These conclusions are based upon the measurement of ten pelves of the variety in question.

SOURCE OF SUGAR DURING LACTATION.—At the meeting of the Biological Society of Paris on April 19th (*Gazette des Hôpitaux*, April 26th), Dr. De Sinety offered some remarks on the relation which exists between the mammary secretion and the presence of sugar in the urine. In the normal condition of lactation the urine presents no traces of sugar, this only occurring when the secretion of milk is arrested or impeded, and disappearing when the secretion takes place regularly and abundantly. Professor Paul Bert recently (*Medical Times and Gazette*, April 12th, p. 496) reported to the Académie des Sciences the results of some experiments with the object of determining the origin of the sugar of milk, whether it was formed either in the mammary gland or pre-existed in the blood of the general circulation. M. De Sinety has made the same experiments, and, after the extirpation of the breasts, he has only met with sugar in the urine. Professor Bert first met with contradictory results from his experiments, but having finally found sugar in the urine, he contended that it had existed in the blood and was probably furnished by the liver. To his view Dr. De Sinety opposes the fact that in a case of this kind analysis exhibited no increase of sugar in the blood, as it should have done were Professor Bert's views correct. As to the part he attributes to the liver in the production of this sugar, it is a mere hypothesis, for the parallelism which it supposes to exist between the glycogenic function of the liver and the quantity of sugar existing in the milk has in nowise been demonstrated to exist.

LAPAROTOMY IN TUBAL PREGNANCY.—In a recent number of the *New York Medical Record*, an account is given of what is believed to be the first occasion in which laparotomy has been performed in a case of hæmorrhage from rupture of the Fallopian tube. Dr. Braddon performed the operation two hours after the diagnosis had been made, the patient being already in a state of collapse. A considerable quantity of clotted blood was removed, and a rupture of the left Fallopian tube discovered. Ligatures having been passed through the broad ligament, the ovum was removed entire, and the hæmorrhage controlled. After some signs of rallying, the patient eventually died 47 hours after the performance of the operation. At the autopsy it was shown to be a case of tubo-interstitial gestation, the portion of the tumour encroaching on the uterus being filled with adherent coagula. Notwithstanding its fatal issue, the operation proves that the point of rupture in these cases may be reached without difficulty, and that the bleeding parts may be effectually secured; and there can be no doubt but that the patient would have had a better chance could the operation have been performed earlier. Her eventual recovery would, however, have been very unlikely even then.

. Influence of Menstruation and Pregnancy on the Blood Corpuscles.—Dr. Maurel terminates a paper, in the *Archives de Tokologie* for December, with the following conclusions:—(1) The number of red corpuscles in women is always less than in men of the same race. (2) This inferiority is due to the menstrual flux, which diminishes their number in a very marked manner during the following fortnight. (3) This law holds good in European women as well as in Indians and negresses. (4) The white corpuscles are more numerous, especially as compared with the red, in women than in men of the same race. (5) The white corpuscles pretty nearly pursue an inverse course to that of the red, being numerous during the menstrual period, and then diminishing until the next period. (6) The observations made during pregnancy are as yet too few to obtain a clear idea of its influence; but it would seem that the increase in the number of red globules observed as the menstrual period recedes, continues, when, under the influence of pregnancy, the hæmorrhage is not reproduced. This increase may even go on to the third month, when, under the influence of causes as yet unknown, the number diminishes again, to increase once more towards the seventh month. But while ascertained facts should be borne in mind, further observations are required to render them conclusive.

Corrosive Sublimate and Iodoform in the Puerperal State.—Valuable information is obtainable from the report of the discussion (in the Fifty-sixth Congress of German Physicians and Naturalists) on Kehrer's paper on Sublimate Injections (*Archiv für Gynäkol.*, Bd. xxii., Heft 1). Mercuric chloride is shown to be odourless, and cheaper and more soluble than carbolic acid. Keustner, who obtained the uterine secretions by means of tubes direct from the interior of the womb, discovered that the micrococci, which normally abounded in them, disappeared promptly after sublimate injections, but only slowly after carbolised injections. Bardelehner's experiments seem to show that a solution of 1 in 10,000 is sufficiently energetic. Ehrendorfer contributes an important paper, "Ueber die Verwendung der Iodoformstäbchen." He recommends iodoform pencils containing 90 to 150 grains of pulverised iodoform, and fifteen grains each of gum arabic, glycerine, and pure starch, which are easily soluble and flexible; they are thus readily introduced into the uterine cavity, after the genital tract has been irrigated with an antiseptic lotion. The iodoform was only used as an intra-uterine pencil in labours which were abnormal, or which were followed by purulent endometritis, &c. He reports in detail 29 cases, nearly all severe, in several of which the patient's condition was rendered desperate by the existence of gangrene, erysipelas, and other serious complications. König has shown that iodoform intoxication is rare when not more than ten grammes (about 150 grains) of pure iodoform are applied.

"Woman" and "Ovary-Man."—Professor Goodell, in a clinical lecture on removal of the ovaries (*Philadelphia Medical Times*, December 29th) observes:—"As I have often said to you, the word 'woman,' or 'womb-man' is a misnomer. She is a woman because she has ovaries, not because she has a womb. A woman who is born without ovaries remains a child and undergoes no development, while, on the other hand, many a woman is born without a womb, and yet has all the development and attributes of womanhood. The scientific label of woman should be 'ovary-man.'" Of oophorectomy Dr. Goodell says, "The operation is still young, and, I think, has been abused, and is in danger of being abused. It requires the utmost caution on the part of the surgeon to decide whether or not to remove the ovaries. The extirpation of these organs does not unsex the woman in regard to her appearance, or to her place in society—it simply prevents her from having children There are several cases reported in which both ovaries have been removed by careful surgeons, and yet the woman has, months or years afterwards, given birth to a child. This has most likely been due to the presence of a third ovary with its tube. I have never met with such a case, but there are numerous instances on record in which a third ovary or ovarian structure has been found in the broad ligaments, apart from the two ovaries."

Premature Labour at the Paris Maternité.—In a paper read some time since at the Académie de Médicine (*Union Médicale*), Prof. Hervieux stated that of the 16,173 deliveries which took place at the Maternité during the period 1861–82 inclusive, 5,236 were premature, or about 32 per cent. During the first six years of the period the proportion was as high as 33·96; while during the last six years it was only 27·50. The proportions did not bear any relation to the fact that the years were years of prosperity or adversity, and Prof. Hervieux, without denying the existence of other influences, believes that the chief cause of the high proportion is the sanitary condition of the Maternité itself, his proportion corresponding to that of its mortality curve. He attaches much importance to the influence of residence in a hospital upon a pregnant woman, the chances of premature labour increasing in proportion to the length of this. As practical conclusions he recommends that during the prevalence of epidemics maternités should be closed to pregnant women, and that at other times they should not be admitted until as near the time of their expected delivery as possible.

A Case of Tubal Pregnancy is recorded in the *Boston Med. and Surg. Jour.* (Jan. 10th). The patient was healthy, aged 32, married two years, and had a normal confinement eleven months before this illness. The symptoms were sudden and severe. At 4 p.m. she experienced pain in the right ovarian region, with faintness and vomiting; at 7 p.m. there was a collapse, and she died four hours later. At the autopsy the abdominal cavity was found filled with blood. There was a rupture of the right Fallopian tube, within which lay the fœtus. The fœtal head presented at the opening, which was about the size of a three-cent silver piece. The following points were noted:—The thinned edges at the site of rupture; the decidua in the uterine cavity; the partially developed placenta, and the chorion villi in process of atrophy; the corpus luteum in the ovary of the opposite side.

Ovariotomy in a Young Girl.—Dr. Duchamp relates in the *Archives de Tokologie*, for January, the case of a girl, eight and a half years of age, who came under his care on account of a tumour situated a little to the right of the umbilicus. It was round and firm, with indistinct fluctuation, and no adhesions to the wall of the abdomen, and was very moveable. Its development had been rapid, and it now by its tension caused some inconvenience. Although its precise seat could not be determined upon, its removal under chloroform was resolved upon. When an incision had been made, the centre of the tumour projected between the lips of the wound and had a very cystic aspect, and after a litre of liquid had been discharged, the mass was drawn out, and proved to belong to the left ovary. The pedicle was seven or eight centimetres in breadth, and was divided by means of Paquelin's cautery and returned into the abdomen, having been tied with antiseptic silk. The tumour proved to consist of the ovary and the greater part of the tube. The child made a rapid recovery.

An Overdose of Chloral During Parturition.—To a young and healthy patient, in her third labour, one hundred grains of chloral hydrate were given, in divided doses, in the course of forty-five minutes, in mistake for three doses of fifteen grains each. The patient became heavy and drowsy, but could be temporarily roused; the pulse was between sixty and seventy per minute; the pains became slow and ineffective. Fifteen minutes after the administration of the last dose of chloral, the membranes were ruptured, and twenty-five minutes later the child was feebly expelled by natural efforts; it was excessively pale, but began to breathe and cry after moderate efforts on the part of the accoucheur, but the skin did not exhibit its natural colour for several hours. The placenta soon followed the child. Two drachms of fluid extract of ergot were given, and half an ounce of brandy. An hour after the birth, the mother was in fairly good condition, and both she and the child made a good recovery.—*Boston Medical and Surgical Journal*, February 14th.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 23RD, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

A Case of Pyelo-lithotomy.

MR. W. ANDERSON read a paper on the above case. The patient, a joiner, aged 20, was admitted into St. Thomas's Hospital, in July, 1883. The symptoms, of nine months' standing, were characterised by the presence of hæmaturia and pain in the left loin, aggravated by exertion and relieved by rest. The urine deposited crystals of uric acid, but contained no admixture of pus. Some fulness and tenderness in the loin, with increase of the area of percussion-dulness, appeared about a week before the operation. An operation was performed on September 10th, 1883, under strict antiseptic precautions. The kidney was reached by an oblique incision three and a-half inches in length, parallel to, and three fingers' breadths below, the eleventh rib (the twelfth rib was not to be felt externally.) On exposure of the organ, a stone was detected by digital exploration in the pelvis renalis, and was reached by incision of the membranous wall of the duct. An attempt was made to extract the calculus by means of the forceps, but failed in consequence of its firm fixation. It was then dislodged by the finger; no hæmorrhage occurred after the completion of the parietal incision. After the insertion of a drainage-tube, the wound was closed with silk sutures, and dressed antiseptically. The progress was uninterruptedly good, except for the appearance of slight toxic symptoms, due to absorption of carbolic acid, on the second and third day after operation. The urine escaped through the wound in small quantity during the first twelve or eighteen hours, after which the whole of the secretion was passed *per vias naturales*. The discharge remained aseptic throughout. The temperature rose to its highest point, 102·2°, on the second day, and sank to the normal level at the end of ten days. The drainage-tube was removed on the seventh day, and the antiseptics were abandoned after the end of the second week. By the middle of October, about five weeks after the operation, the wound had become reduced to a superficial sore, and the patient was able to get up and walk about the ward without pain. The urine presented only a trace of albumen and a few cell forms. He was discharged cured on the 1st November. The calculus weighed 60 grains when entire, and consisted chiefly of calcium oxalate, with about 10 per cent. of uric acid and traces of magnesium phosphate. It was shaped like a molar tooth with a rough crown and two fang-like processes, between which was a circular sharply marginated depression. A piece of renal substance had become embedded in the depression, and was so firmly adherent that it was torn away from the organ during the extraction of the stone. The case was referred to as the eighth of the published examples of operation for removal of a stone from the kidney by incision through the healthy parietes. Of the eight cases seven were successful, one ended fatally. The main element of the calculi was uric acid in two instances, calcium oxalate in four, and calcium phosphate in two; and the weight ranged between 26 grains and one ounce. The operative procedures differed principally in the treatment of the kidney; in six cases the stone was reached by section of the renal substance; in two by incision of the pelvis renalis; severe hæmorrhage resulted in two of the former group, but was checked by pressure. The cure was perfect in the cases of recovery, and in no instance was permanent urinary fistula a sequel; the secretion ceasing to flow through the wound after an interval ranging from eighteen hours to eighty-one days. The name of pyelo-lithotomy was proposed to distinguish cases in which the stone was extracted through an aperture in the pelvis renalis from cases of nephro-lithotomy in which, the renal parenchyma was incised for the same purpose. It was suggested that the former procedure, when practicable, was preferable to the latter on account of the removal of the danger of wounding the large vessels in the neighbourhood of the ileum, while in the two cases in which the plan had been adopted, the flow of urine through the wound speedily ceased, before the end of eighteen hours in one instance, on the sixteenth day in the other. As incidental points for notice in the case recorded, mention was made, firstly, of the absence of the enlargement or displacement of the kidney that might have been anticipated from the lumbar fulness, dulness, and tenderness observed before the operation; and secondly, of the impossibility of distinguishing the twelfth rib by external examination, the lowest palpable rib being the eleventh, a peculiarity which, if undetected, might bring the pleural sac into danger.

Mr. R. J. GODLEE congratulated the author of the paper on his success. He thought that if any further operation should be necessary in the case it would be better to have recourse to nephrectomy. In these cases, in which several small stones had been discharged, it not unfrequently happened that the pelvis and calices of the kidney contained a large number aggregated together. To make a titular distinction between the operation through the renal tissue and that through the pelvis seemed hardly necessary. He did not think that any severe hæmorrhage need be dreaded on section of the kidney, whilst the process of opening the pelvis of the organ necessitated deeper section. In a case of his own he had been able to make his way to the stone by means of tearing with the finger-nail, and the result had been satisfactory.

The PRESIDENT enquired whether any manifest errors of diet had been detected in the previous history of the case.

Mr. HENRY MORRIS considered that experience was not yet sufficiently large to warrant any definite opinion being given as to operating through the renal substance or through the pelvis. The best rule would probably be to attack the stone through whichever of these tissues it could be most easily felt. To propose a new name would complicate matters unnecessarily. Hæmorrhage on dividing renal tissue was generally controlled with ease, and probably by the process of tearing with the nail the risk of hæmorrhage would be still further lessened. Further experience was required to show whether the tendency to form renal fistula might be greater through one part than through another. In a case of his own no escape of urine to speak of had occurred through the wound during the first 24 hours, and none had passed since. He thought that surgeons would now be justified in searching the kidney very fully, in cases where the clinical evidence of the presence of stone was undoubted. In one case he had removed an otherwise healthy kidney after seeking in vain for a stone, which was only discovered with some difficulty afterwards. He thought that in women, and perhaps also in men, the bladder should be explored by the finger, owing to the frequency with which stones may become impacted in the orifice of the ureter, especially where bladder symptoms had been complained of. He related a case in his own experience in which this condition was present.

Mr. ANDERSON in reply stated that in the general habits of his patient there had been nothing to give a clue to the causation of the calculus. The pain had been exclusively on the left side, and hence the stones had probably not come from the right kidney. He agreed in the advisability of attacking the stone through the pelvis or through the renal substance according to the conditions present in each

case, but thought that where no special indication was given, the pelvis should be selected.

Sequel to a Case of Aortic Aneurysm.

The SECRETARY, for Dr. FINLAY, read notes on this subject. The case was first brought forward, and the patient, a female, aged 32, shown at a meeting of the Society on the 10th February, 1882. A full report appears in the "Transactions," vol. xv., p. 151. She presented well marked signs of a sacculated aneurysm of first part of the aorta, with aortic and mitral incompetence, and had been treated for six months in the Middlesex Hospital, on Tufnell's plan of restricted diet in the recumbent position, with increasing doses of iodide of potassium. For two years and a-half subsequently she had attended as an out-patient, having taken almost continuously iodide of potassium in considerable doses. The question proposed for discussion when the patient was shown, was the propriety or otherwise of operative treatment by electrolysis, or the distal ligature, the arguments for and against which were stated in the paper then read. As, independently of other considerations, she was unwilling to be again laid up in the hospital, it was resolved merely to continue the treatment with iodide of potassium, and she attended regularly at the out-patient department once a fortnight, until her death, which took place on March 26, 1884. On the last occasion on which she was examined (viz., on 18th January, 1884), she stated that she felt better in her general health than she had done when first shown at the Society's meeting in 1882. As to her physical condition, the notes then made were practically the same as those read on the former occasion. On March 22, however, she was seized with shortness of breath, cough, and pain in the chest, and she died on the 26th with symptoms of bronchitis and congestion of the base of the left lung. At the *post-mortem* examination the aneurysm was found to be adherent to the cartilages of the second, third, and fourth ribs on the right side, and to the adjacent part of the sternum. The sac, which was divided into two parts by a calcareous ridge, sprang from the aorta immediately above the aortic valve, and contained some loose, soft, decolourised clot. It was roughened and thickened by patches of atheroma, which had proceeded in many parts to calcification. Part of the sternum and of the cartilages of the third and fourth ribs was croded. The cusps of the aortic valve were thickened, puckered, coherent, and obviously incompetent. The muscular substance of the heart was pale and soft, and under the microscope showed advanced granular degeneration. The lungs were œdematous, and the base of the left was congested and pliable, breaking down under pressure with the finger. The results of the *post-mortem* examination bore out the conclusions arrived at when the case was first brought forward. In particular, the condition of the aortic valve established the fact of the aortic regurgitation, regarding which doubts had been expressed when the patient was shown. As to the effect of treatment, there was no deposit of fibrin or consolidation of the sac. Probably all the methods of treatment used acted in the same way by lowering the blood pressure. It was worthy of note that the aneurysm was not directly the cause of death, which was due rather to the degeneration of the heart's substance, consequent upon the incompetence of the aortic valve.

No discussion followed.

Two Cases of Hernie en Bissac.

Mr. GOLDING-BIRD read a paper on these cases. The first was that of a woman, aged 47, on whom he had operated in 1878 for right femoral hernia, opening the sac and removing omentum. In December, 1880, he again operated for fresh strangulation, and then found the peculiar condition described, of which however there was no mention in the notes of the first operation; presumably, therefore, it had developed subsequently. Now, besides the usual and large hernial sac, there was, leaving it at right angles, a process of sac just the size and shape of the finger (thumb) of a glove, and passing down into the right labium. It left the parent sac just below the pubic spine. The main sac was, at the close of the operation, dissected up and removed, being ligatured at its neck; but the labial portion, being firmly attached, was cut off and left *in situ*. There appeared to be every prospect of a radical cure resulting. Though strictly the term *en bissac* was applicable only to inguinal hernia, yet he had employed it here, so exactly did this hernia agree with the requirements for that condition, save in regard to its position in the thigh. The other case was that of a woman, aged 60, with twenty years' history of left inguinal hernia. After wearing a truss the first ten years it disappeared until two years ago, when, in addition to the inguinal protrusion, there developed a large and subcutaneous tumour, lying above Poupart's ligament and between the crest of the ileum and the external abdominal ring. Twice it had appeared and then in a few days nearly subsided, but failed to do so on a third occasion, the beginning of this year. Kelotomy was performed, and it was then found that whilst the original hernial protrusion existed at the external ring, a large and laterally-connected sac had burst through the front part of the inguinal canal, leaving only a broad external pillar, and lay in the aponeurosis of the external oblique. The bowel was relieved, after division of the internal ring, without opening the sac; this was then opened and much inflamed omentum removed. The patient sank from exhaustion on the third day. Mr. Golding-Bird referred to a case of Mr. Luke's, published 30 years ago, almost identical with his own; but the great peculiarity of this case he considered to be in the double sac; the absence of taxis or any violence ever having been employed to induce its formation; its bursting through the external oblique fibres in front of the canal, and its subcutaneous position, that of intra-parietal herniæ being always inter- or sub-muscular.

The paper did not give rise to any discussion.

A Case of Impaction of Bone in the Larynx.

Dr. FREDERICK TAYLOR read notes of a case contributed by himself and Mr. Golding-Bird. A man, aged 63, came to Dr. Taylor as an out-patient, with a cough which he had had for more than five months. Though he did not complain of his throat, a slight stridor led to an examination of the larynx, when a foreign body, resembling bone, was seen lying below the cords, and extending from front to back of the larynx. It appeared to be about ¼-inch broad, but there was breathing space on either side of it, and on phonation the cords closed easily over it. On being questioned, he remembered that four months previously he had taken some sheep's head broth, and half-swallowed with it a piece of bone. This stuck in the back of his throat, and he was unable to move it with his fingers; but his wife with the tablespoon pushed the bone down his throat, and he thought it was safely disposed of. For a week his throat was sore, and for two or three days he spat some blood, but since then he had not had any inconvenience from it. He was admitted into the hospital, and was found to have the physical signs of emphysema, with expectoration of much frothy mucus, and metallic cough, preceded by stridulous inspiration. After a few days he was transferred to a surgical ward, and Mr. Golding-Bird proceeded to remove the bone by laryngotomy. On dividing horizontally the

crico-thyroid membrane, and putting in a tracheal dilator, the bone was at once seen, and removed with Toynbee's ear forceps. A second smaller piece, the size of a pea, was seen impacted in the mucous membrane covering the cricoid, and also removed. The patient made a rapid recovery, and when seen again, two years later, the larynx appeared normal; the cords moved freely, but were slightly pinker than usual. The larger piece of bone removed measured ¾-inch in length, ⅝-inch broad, and ¼-inch thick. Attention was called to the large size of the foreign body, the curious way in which it became impacted, its long retention without inconvenience to, and, indeed, without the knowledge of, the patient. Its large size, and the apparently firm impaction below the cords led to the adoption of the external operation rather than its removal by the mouth.

Dr. DE HAVILLAND HALL asked if any attempt had been made to remove the bone by the forceps. He thought that such a proceeding would have been quite feasible, and was generally preferable to any external laryngeal operation, which could not be altogether free from risk. In the present case the operation had been in every way successful, but he thought that an attempt at endo-laryngeal removal should always be made in such cases.

Dr. COUPLAND mentioned two cases of impaction of bone in the larynx. In one case the fragment had proceeded from an area of necrosis in the base of the patient's own skull, and in the other a large mass of bone had found its way into the air-passages and remained undiscovered, although giving rise to pleurisy and pneumonia at intervals of several weeks, until brought to the surface during a violent fit of coughing.

Mr. GOLDING-BIRD had not used the forceps in this case, because the bone had been impacted for a long time, and lay fairly below the vocal cords. It was seen by the laryngoscope to be lying with its broadest surface uppermost, and presented nothing for the forceps to grasp.

Dr. F. TAYLOR thought that the endo-laryngeal operation would have lacerated the laryngeal tissue considerably; the bone was in two pieces, and the removal of the larger fragment might have allowed the smaller to drop into the trachea. Division of the crico-thyroid membrane did not appear to be a very serious operation.

The PRESIDENT referred to the six papers which still remained to be read, and appealed to the members to decide whether an extra meeting should be held for the purpose.

After some conversation it was decided by a majority of votes that no further meetings should be held this session.

The following Living Specimens were exhibited:—

(1) Uncommon lateral curvature of the spine, with extreme osseous deformity; by Mr. BERNARD ROTH. (2) Removal of dislocated astragalus; (3) Case in which the intestine was opened, stitched to the sac and returned to the abdomen; (4) Splint for treatment of dislocated internal semi-lunar cartilage; by Mr. HOWARD MARSH.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 27TH, 1884.

GEORGE JOHNSON, M.D., F.R.S., President, in the Chair.

An Average or "Composite" Temperature Chart of Small-pox.

Dr. HERMAN had constructed the charts described in this paper from observations made during the small-pox epidemic of 1871, in a temporary hospital at Shoreditch. These charts were made up by adding together the figures indicating the temperatures in the different cases for the same period of the day, and dividing the total by the number of observations. By this method the average temperature of all the patients from day to day, instead of that of each individual patient, as was the case in ordinary temperature charts was shown.

Gangrene of the Lung Treated by Drainage. Recovery.

Dr. CAYLEY, and Mr. GOULD contributed a paper on the above subject, of which the following is an abstract:—The patient was a girl, aged 12, who was admitted into the Middlesex Hospital, on January 18th. Four years ago she had had scarlet fever, which was followed by otorrhœa. On admission there was an acute abscess over the mastoid process on the left side, and extensive denudation of the bone about the external auditory meatus. The abscess was opened, and Mr. Gould gouged away some soft necrosed bone from the mastoid process. The patient progressed favourably till January 28th, when symptoms of pyæmia developed. She had repeated rigors, with high fever of a remittent type. On February 2nd, signs of pleurisy with consolidation at the base of the right lung appeared. On February 7th her breath became offensive, and she began to spit up small quantities of stinking pus. On February 16th, these symptoms having continued, and the child having become extremely emaciated and prostrate, it was decided to drain the gangrenous cavity. There was now dulness over the right base as high as the angle of the scapula, and at one point some bubbling crepitation. Mr. Gould accordingly punctured the lung with a large sized trocar and cannula, and introduced through the latter a drainage-tube. Stinking pus and a sequestrum of gangrenous lung were discharged through the tube. The child rapidly improved, and was discharged on March 27th.

On the Treatment of Pus-secreting Basic Cavities of the Lung, by the Method of Paracentesis and Free Drainage.

A paper on this subject was read by Dr. BISS. The author grouped pus-secreting basic lung cavities under three heads: (1) Those in which paracentesis is imperatively called for; (2) those in which it is unjustifiable; and (3) those in which it is a question of special difficulty whether it should be performed or not. A case illustrative of the last group was then related. A man, aged 32, with a satisfactory family history, who had not suffered from any previous pulmonary disease, had been affected with cough and profuse expectoration for six months. On admission to the hospital he presented at the right posterior base dulness, reaching as far as the spine of the scapula, with absence of breath-sounds and vocal fremitus. The heart's apex beat half an inch outside the nipple line. The case was regarded as one of abscess at base of the lung with slight effusion into the adjacent pleura. An exploratory puncture failed, however, to detect any fluid. Soon afterwards obscure friction sounds developed over the dull area, and then loud cavernous respiration with intensified voice sounds, the pyrexia and hectic symptoms becoming more marked. About a fortnight later—medicinal means having failed to give relief—a second exploratory puncture was made with negative results, except that the lung was judged to be adherent. The course of the case continuing unsatisfactory paracentesis was resolved on. Professor Marshall made an incision two inches in length along the tenth intercostal space, over the point of maximum intensity of the cavernous sounds, reaching and exposing the pleura; a trocar was then gradually inserted to a depth of four inches, when a cavity was entered, from which whiffs of fetid air were expelled, and a scanty blood-stained discharge flowed. The wound and cavity were temporarily plugged to staunch hæmorrhage, and next day a drainage-tube was inserted, through which a puriform discharge began freely to escape. The symptoms were considerably, but not wholly, relieved. Ten days later signs of cerebral abscess appeared, and in another ten days the patient sank. The autopsy revealed a number of bronchiectatic cavities in the right lung, one of

the largest of which had been pierced and drained by the operation. The lung was invaded by fibroid change, and much contracted. Two abscesses had formed in the brain. The opposite lung and all the other organs were healthy. No miliary tubercle was perceived anywhere. The following diagnostic points were then discussed: (1) The brief history of disease in comparison with the apparently long-standing morbid conditions. (2) The displacement of the cardiac apex. (3) The remarkable alterations which took place, during the course of the case, in the auscultatory signs. (4) The invariable absence of tubercle-bacilli from the sputa, and the inspissated secretions found after death in the lung cavities. In conclusion, the drawbacks and advantages of paracentesis of pulmonary cavities (apart from phthisis) were discussed, and a brief recapitulation of some of the literature of the subject was given.

Mr. Godlee said that there were two principal difficulties which presented themselves to the surgeon when called upon to interfere in such cases as those under discussion: first, the difficulty of ascertaining the exact position of any supposed pulmonary abscess; and, secondly, the impossibility of determining whether or not adhesions between the visceral and parietal pleuræ had occurred. He recommended to the physicians the further development of the "fine art" of localising the position of pulmonary cavities, and mentioned some cases in which, though the physical signs appeared to point clearly towards the existence of such, the insertion of a needle at the spot indicated had failed to discover pus. He pointed out that, although no harm may be anticipated from puncturing the lung even several times, considerable deception might result from tapping a bronchus or a small bronchiectatic cavity, leading the surgeon perhaps to open such a space while leaving the larger cavity of which he was in search unrelieved. To illustrate these difficulties, he mentioned a case under the care of Dr. Biss, at the Brompton Hospital, in which two cavities appeared to be clearly indicated by the physical signs, and in which, from the retraction of the chest and the chronic nature of the complaint, it was thought that it might be assumed that complete adhesion between the two layers of the pleura had taken place. A needle inserted at one spot in the back failed to tap a cavity, but a puncture in the upper part of the axilla seemed to pass into one of them. A piece of rib was then excised (a plan which it was urged it is wise to adopt in order that the surgeon may clearly see what he is doing), antiseptic precautions being observed; but it was found that though the lung was much solidified, and therefore scarcely collapsed at all, very few adhesions had taken place. In this case Mr. Godlee stitched the lung to the opening in the pleura, and after a fortnight, although adhesion was not perfect, another attempt was made by puncturing the lung in various places to open the cavity; but all the efforts were fruitless. It could not be doubted that the cavity was present, for at the end of the operation the child brought up a large quantity of thick stinking pus, showing that the failure to tap the cavity did not depend on the fact of its having been previously emptied by coughing; and it was stated that further attempts would be made to reach it. Mr. Godlee expressed the belief that it need not be anticipated that the entrance of even putrid pus into such a pleura would result in any very serious consequences; but at the same time, that such an accident is not unassociated with danger, and is one that should if possible be avoided. He then detailed another case, now under the care of Dr. Bastian, in University College Hospital, in which he had opened a small pulmonary cavity, resulting no doubt from the breaking down of a pneumonic lung, as illustrating the ease with which the operation may be performed when the circumstances are propitious, and the great benefit which the patient may derive from the operation. In conclusion he exhibited two instruments intended for tapping abscesses of the liver, but which are equally well adapted for a similar condition in the lung—one, devised by Sir Joseph Fayrer, a cannula and trochar, both of which are provided with a groove, so that after withdrawing the latter, the former can be used as a director to guide the knife or gorget or any other dilating instrument which may be preferred; the other a trochar which is provided with a celluloid cannula, which can be left in the abscess and cut off at the level of the skin. This will soften, more or less, at the temperature of the body, and after a day or two can be replaced by an india-rubber drainage tube. It is intended that it shall be fixed in position by tying pieces of silk to the end after cutting it level with the surface of the body.

Mr. Walsham related a case which he had treated, and which was believed by his medical colleagues to be one of a phthisical cavity in the apex. The man was suffering from hectic, and was greatly emaciated. There was a copious and at first fœtid discharge, and the cavity was washed out with carbolic solution; this at first rather increased the discharge; subsequently the carbolic solution was better tolerated, the cavity closed, and the patient was much relieved. Although it was open to consider the case as an apex empyema, yet his medical colleagues had been quite clear that it was not an empyema, but rather a cavity in the lung itself.

Dr. Broadbent had recently had under care an officer from the West Indies. He had gone to America in cold weather and been taken ill. His life had on a former occasion been endangered from some pneumonic affection. A cavity formed in the base of the left lung, from which a quantity of very fœtid pus was continuously expectorated. The patient being in a very desperate condition, he had made into it an opening, and a quantity of pus was let out. The cough was somewhat lessened by the operation, but the temperature remained high, and the hectic continued. A further exploration was decided upon, but meanwhile, after an unusually free escape of pus, the man began to improve, and appeared as if about to recover. He (Dr. Broadbent) then left town for his holiday, leaving the patient under the care of a colleague, it having been decided that he was to start for the South of France on Dr. Broadbent's return. The patient, however, on his own authority started off to the Continent at once in the hottest of hot weather, and he died shortly after his arrival. Dr. Broadbent could, unfortunately, give no other particulars of the case. He thought Dr. Cayley's case an excellent one, but he had some doubts about that of Dr. Biss'; it appeared to him, from the symptoms described, less likely to have been a cavity than consolidation.

Dr. Powell thought the two cases were really illustrations of the two classes of disease which might be expected to benefit by paracentesis and drainage, and in this respect he differed with Dr. Broadbent as to Dr. Biss' case. Dr. Cayley's case was a typical one of a single, pus-secreting abscess, acute in origin. The patient was being exhausted by hectic, and poisoned by his own secretions, and it appeared to him that the treatment which had been adopted was the only treatment from which any good could have been anticipated. In Dr. Biss' case some interference was clearly indicated, because such cavities could not be otherwise drained. As to the physical signs: there was difference of opinion as to their significance, whether they indicated a chronic fibrosis of the lung with numerous bronchiectatic loculations, intercommunicating, or a large cavity. The absence of cavernous breath sounds rather indicated that a large cavity did not exist, but smaller cavities might well exist nevertheless. Gurgling was absent on account of induration of the lung. The advantages of paracentesis were nevertheless great, and served for drainage purposes; the cough and expectoration were diminished, while the presence of a drainage tube in such a cavity established a centre around which cicatricial tissue formed. Dr. Biss' patient had had ample opportunity for getting better, but had not done so; hence he thought the surgeon was called upon and justified in attempting further measures. There were some risks, but these were not greater than the patient ran from the disease itself. He thought there were no signs by which an adherent pleura could be diagnosed: nevertheless, we might judge from pathological analogies, such disease in the lungs would rarely exist without more or less pleural adhesion,

Dr. J. Kingston Fowler said a case had lately been under his notice at the Brompton Hospital for Consumption, which he thought of sufficient interest to be mentioned in this discussion:—The patient was a man, aged 47,

of a healthy family, and who had never suffered from any serious illness previous to November, 1882; when he visited a dentist for the purpose of having a tooth (the second lower molar on the left side) extracted. The dentist in using an elevator allowed the tooth to slip; the patient, feeling something at the back of his throat, coughed and took some water. He then asked to see the tooth, but was told that he must either have swallowed it or spat it out into the basin. Immediately afterwards, on his rising from the chair, he was seized with intense dyspnœa, and from his own account was evidently for a time in great danger of asphyxia. This condition, which was accompanied by violent coughing, passed off in a few minutes, and was followed by a feeling of pain above the right nipple. The cough continued nearly all through the night, and for the next fortnight it was very severe, coming on in frequent paroxysms. He then went to St. Thomas's Hospital, where he was admitted as an in-patient, and remained a fortnight under the care of Dr. Sharkey. His tale of misfortune was completed by finding that the wrong tooth had been extracted. Whilst there, an emetic was tried without effect; he was also inverted, preparation being made for tracheotomy should it prove necessary, but there was no sign of any movement of the tooth. At this time he was expectorating a considerable quantity of frothy muco-pus, which on one occasion only was streaked with blood. About two months after leaving St. Thomas's he appeared among his (Dr. Fowler's) out-patients at Brompton. At that time he was expectorating in the twenty-four hours nearly half-a-pint of this frothy mucus, mixed with flocculent masses, and his cough was severe and paroxysmal. His appearance indicated emaciation, and he stated that since his illness commenced he had lost fifteen pounds in weight; his appetite was bad, he had occasionally night-sweats and flushes, and he felt generally weak and ill. He suffered from dyspnœa and increased cough on the slightest exertion. Respirations were 30 per minute. The pulse was 120, full and regular. The temperature was 99·2° F. He had not had hæmoptysis. On examination, his chest appeared fairly well formed, there was a little retraction of the first and second interspaces at the right apex, and diminished expansion at the right base; vocal fremitus was found to be much diminished below the level of the angle of the scapula. On percussion in the right interscapular region, comparative dulness was noted as commencing at the sixth dorsal spine, gradually increasing in a downward direction, becoming absolute at the angle of the scapula, and so remaining over the area of the lower lobe below that level. On auscultation on the right side, the breath sounds over the supra- and infra-clavicular and mammary regions were rather harsher than normal, and expiration was slightly prolonged. There was a pleuritic friction sound in the lower axillary region, after a deep inspiration. In the interscapular region the sounds were bronchial, but at a spot two inches below the spines of the scapula there was distinct evidence of the presence of a cavity of considerable size. At the left base there were some muco-crepitant râles. The cardiac apex was in the normal position, and the heart sounds were normal. Dr. Symes Thompson, having kindly placed a bed at his disposal, joined Professor Marshall and himself in consultation, and it was decided to puncture the cavity with a view to promote its contraction by securing perfect drainage and, at the same time, if possible, to remove the tooth. They concluded that there could be no doubt that the surfaces of the pleura were adherent over the posterior aspect of the lower lobe. The operation was performed by Mr. Marshall, on March 2nd; the patient being first placed under the influence of chloroform, and afterwards of ether, and full antiseptic precautions being observed, a trocar and cannula of a form suggested by Dr. Hicks, then Resident at the Brompton Hospital, was passed into the lung, at a point two inches distant from the vertebral spines, between the eighth and ninth ribs. The trocar being withdrawn, an incision was made downwards and outwards for an inch, from the point of its insertion, and a gorget, of a form suggested by Dr. Hicks, was slipped along the cannula; both were then withdrawn. At this moment some thick sanious pus, mixed with air, welled up through the wound, and the patient shortly afterwards coughed up two or three times a small quantity of blood. Mr. Marshall then introduced his fingers into the wound, and found that it led to a cavity, in front of which was a dense wall, consisting probably of solidified lung. A probe was introduced, and was found to pass an indefinite distance in a certain direction, when it was clearly in a large bronchus. Mr. Marshall at one time thought he could feel the tooth, but this was rather doubtful. A pair of dressing forceps was passed in and the wound dilated, but nothing was extracted. A dissecting cannula was then introduced, and with a blunt-pointed bistoury a deep incision was made in the lung; this was immediately followed by a considerable hæmorrhage, quite half-a-pint of blood escaping. The cavity was then packed with strips of carbolised gauze, over which several pieces of lint were laid, covered by a many-tailed bandage. The gauze was kept damp through the afternoon, and at 8 p.m. an ordinary antiseptic dressing was applied. At that time his temperature was 99·4° F. He slept during the night after two hypodermic injections of morphia. He had expectorated about six ounces of viscid reddish mucus. On March 5th the gauze plugs were removed from the cavity, a drainage tube was inserted, and an antiseptic dressing applied. The evening temperature was 101° F., pulse 120; cough troublesome, and the sputum muco-purulent. The wound was dressed on March 10th; there was only a small quantity of discharge, similar in character to the expectorated matter. The expectoration was purulent, measuring about five ounces in twenty-four hours. On the 14th the wound was again dressed. There was not much discharge; night-sweats were increasing. On the 18th a careful examination of the chest was made; the cavernous sounds were found to be audible over a smaller area than previously, being most distinct just above the opening of the drainage tube. A probe was introduced for a distance of seven inches; nothing was felt but the rings of a large bronchus. The antiseptic dressings were omitted on March 28th, when his general condition seemed improved, but the night-sweats still continued; further, he had been taking sulphate of atropia, and also quinine and cod-liver oil. During April the night-sweats ceased and the cough became less troublesome; the expectoration averaged from four to six ounces a day; it was purulent in character, and occasionally contained some streaks of blood. On May 29th the patient was again placed under chloroform and the wound examined, but nothing of material importance was discovered. The patient remained in the hospital up to July 14th, the general condition showing improvement, but the local signs did not undergo much change whilst in the hospital. The sputum was frequently examined, but was free from bacilli. He then left for Eastbourne and returned on August 7th. It was then decided that the drainage tube should be gradually shortened so as to allow the opening to close, which it did about the beginning of October, 1883. He became an in-patient again in November, and remained in the hospital through the winter. The expectoration continued to average about five ounces per diem, and was purulent and offensive in character. But little change occurred in the physical signs, which continued to indicate the presence of a cavity in the right lower lobe, which, however, appeared to be considerably smaller than before the operation. At present the patient was in much the same condition, there being still evidence of a small cavity below the angle of the right scapula. The lung around was evidently condensed, a few crackles being audible on inspiration. The patient, he thought, had derived some benefit from the operation, as it was clear that the cavity had undergone contraction on the healing of the sinus. He still continued to expectorate nearly three ounces of muco-purulent fluid a-day, but his general health and strength had improved, and he kept up his weight. There was no evidence of any affection of the upper bones.

Dr. CAYLEY, in reply, said he had little to add to his paper. He thought the Society would hardly fail to gather from what had been said in the course of the discussion, that the lung would bear a very considerable amount of operative interference with impunity. On the whole, he preferred Mr. Gould's method of using a large trocar and cannula, and putting a drainage tube into the lung through it, to Mr. Godlee's plan of incising the lung; there

appeared to be less danger of hæmorrhage. The abscess in the brain had clearly nothing to do with the operation, for of three cases referred to during the evening, in one case there had not been operative interference.

Mr. GOULD agreed with most of what had fallen from Mr. Godlee, as to the surgical aspects of the case, and he considered himself lucky in having hit the cavity. In advocating such a practice as was now being discussed, he reminded the Society that Richter had arrived at the same conclusions 100 years ago, as to the treatment of cavities in the lung. This author thought the cavity should be a single one, not due to tubercular disease, and that the constitution ought not to be undermined, and such appeared to be the view to-night. Mr. Godlee had referred to the desirability of the two layers of the pleura being adherent. He agreed as to this, and believed they were so in a majority of cases; still he thought we made too much of the dangers of their not being adherent. He had just been reading a case published by Professor Krönlein, who had successfully removed a large piece of rib, some pleura, and a portion of adjoining lung for a sarcomatous growth. The record of such cases ought surely to give us courage to proceed; at present we were but just feeling our way.

Dr. BISS said that perhaps an exact diagnosis was not so very important. With symptoms such as had been present, they were justified in making an attempt. In liver abscesses, for instance, they would aspirate and explore, even if they could not accurately locate, an abscess. In the lung it was not by any means an easy matter to locate an abscess with the instruments at present used, which were only trocars about as large as crow quills. In the case of a fibroid lung, collapse did not occur, owing probably to adhesion of the lung. If pleurisy followed, contraction of the lung would necessary result, and close the cavity. Dr. Broadbent appeared to have assumed that his patient had died of the operation. On the contrary, the man died of his disease, and of abscess of the brain, which could not be attributed to the operation.

The Society then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 7TH, 1884.

H. GERVIS, M.D., F.R.C.P., President, in the Chair.

THE PRESIDENT read the addresses of condolence which he had sent on behalf of the Society to her Majesty the Queen and H.R.H. the Duchess of Albany.

The following Specimens were shown.

Dr. CLEVELAND.—A fleshy or deciduous substance voided after labour by a patient who had already voided similar bodies on two previous occasions. It was probably the decidua from the unimpregnated half of a double uterus.

Dr. MATTHEWS DUNCAN.—Microscopical slides of an angioma of the labium majus.

Mr. DORAN.—Ruptured secondary cyst in the wall of a multilocular ovarian tumour.

Dr. HORROCKS.—Rupture of uterus and vagina—longitudinal in direction.

Dr. CHALMERS.—Cyst between tube and ovary, in the broad ligament.

Dr. BANTOCK.—Four fibrous tumours of the uterus removed by operation; the uterus in one case was pregnant.

On Strong Mental Emotion affecting Women as a Cause of Idiocy in the Offspring.

This paper was by Dr. ARTHUR MITCHELL. The author remarks that this cause is often assigned by the mother, but in most cases without sufficient reason, especially as more probable causes can usually be discovered occurring after birth. In some cases, however, he has convinced himself that this is the true cause, especially if the mental state has been protracted, and if the rapidity of developmental changes in the fœtus be considered. Such disturbance may act either as arrest or as misdirection, and probably through the bodily health of the mother. Sudden emotions may in some cases have a similar effect; under such conditions patients have described violent fœtal movements following the shock, and afterwards a cessation of movements for some days. Such movements are probably convulsive, and if so, are quite capable of accounting for permanent mental damage. Mental emotion is known to lead to abortion, sometimes apparently preceded by the death of the fœtus. The paper concludes with an account of 6 cases drawn from 443 cases of idiocy or imbecility consecutively examined, with allusion to 22 other cases, making 28 cases observed in a total of 1,500. In the 22 cases the evidence was less satisfactory.

The PRESIDENT gathered that the effect was presumably produced through the general health of the mother rather than directly on the fœtus.

Dr. WEST remarked that such statistics could not be trustworthy until compared with a similar series, in which no such results had followed from the same causes. The latter class would, in his opinion, prove a large majority. His present opinion coincided with the verdict "*not proven.*"

Dr. FLETCHER BEACH said that, according to statistics collected by him in the Darenth Asylum, fright and other violent mental emotions accounted for about one-tenth of the cases in which histories could be obtained. But in many of these cases there was also intemperance, involving worry and anxiety to the mother, illusage from the husband, pawning of furniture, and want of food. In a large number of cases there was a history of insanity, imbecility, epilepsy or paralysis in the parents.

Dr. CLEVELAND agreed with Dr. West. He related the history of a family of six, three of which (each alternate child) were idiots; both parents were sane, there was a history of insanity on the mother's side, but she had never herself been insane.

Dr. AVELING regretted the absence of histories of insanity and consanguinity from the cases related.

Dr. MATTHEWS DUNCAN observed that Dr. Mitchell did not claim to have proved his theory, but only said he had "convinced himself" of the truth of it. He (Dr. Duncan) thought he had made it highly probable. Dr. Mitchell had already shown that the age of the mother, the number of the pregnancy, and of turning influenced the offspring. Ancell had shown that the injurious or favourable influence of the number of the pregnancy extended over the whole life of the children to adult age, influencing the rate of their mortality. Such facts proved the grave effect of slight causes, and favoured the author's view.

Dr. HEYWOOD SMITH pointed out the omission from the paper of the date in utero-gestation at which the perturbing influence occurred. In physical deformity of the offspring, the mental shock to which the mischief was ascribed by the mother, happened, in his experience, generally between the third and fourth month.

On a Case of Extra-uterine Gestation—Delivery of a Living Child per Vaginam—Removal of Placenta—Recovery.

A paper with this title was contributed by Dr. MATHIESON, of St. Mary's, Ontario. The patient was aged 30, the mother of five children. In November, 1880, menstruation (which had been regular, though scanty for two months) ceased, and abdominal pain began. In December, 1880, a lump was noticed low down in the left inguinal region. She was first seen by the author in March, 1881, when she had a tumour rising to the level of the navel, filling the left vagina region, and extending two inches to the right of the middle line. The uterus could not be mopped out. The sound passed three and a half inches slightly to the right side and in front of the tumour. There was occasional pain in the tumour, tenderness, and a feeling "like jelly moving," which made her feel sick; painful micturition, irregularity of bowels. The

LIVERPOOL MEDICAL INSTITUTION

tumour continued to enlarge, fœtal movements became stronger, and the pain more severe. On April 12th she had an attack of pain and nausea, with pulse 146, temperature 103·6°, cold extremities and cold sweat; relieved by morphia. A similar attack occurred on April 23rd, another on May 2nd, and another about May 18th. On June 2nd a somewhat similar attack was accompanied by pretty regular labour-like pains, independently of fœtal movements, and accompanied by a red discharge. The tumour continued to grow and the most rapidly growing part was always the most painful. On June 13th occurred another attack like the last, but the pains were bearing down, though no bulging during them could be felt per vaginam. On June 28th she had a very severe attack of pain during micturition, followed by attacks of syncope. The roof of the vagina was filled with a doughy mass, solid on deeper pressure. Operation per vaginam was at once decided on, and performed without chloroform at the patient's request, by cutting with a knife and tearing with the finger-nail. The face of the child was found presenting, and was delivered by forceps easily. It was still-born, but soon revived. The placenta was at the posterior and left side of the cavity, its lower border some two inches from the vaginal roof. It was easily peeled off, a sponge soaked in perchloride of iron following it up. There was very little bleeding. The clots were removed from the cavity, its walls were touched with perchloride, and the operation ended. Much exhaustion followed the operation. The child weighed eight pounds seven and a half ounces, and appeared mature. The placenta was three-lobed, but was destroyed before a careful examination could be made. The after-treatment consisted in washing out the cavity antiseptically. The opening healed in three months. Severe pain in the side lasted for nearly two years after the operation. She was seen in August, 1883, in excellent health, had no pain except after great fatigue; had menstruated normally for six months. The child was healthy, the largest, and a great deal the heaviest of the family. The author discussed the treatment pursued (1st) as to the operation per vaginam, (2nd) the removal of the placenta.

The PRESIDENT doubted the propriety of the vaginal operation and of the removal of the placenta. Each case had to be judged on its own peculiarities; but generally he was in favour of primary operation, abdominal section, and leaving the placenta.

Dr. AVELING suggested the possibility of the sac being a secondary uterus.

Dr. PLAYFAIR disapproved of vaginal operation and of the removal of the placenta; the case as related was most extraordinary, especially in regard to the labour pains described.

Dr. CHAMPNEYS remarked that such pains are part of the ordinary phenomena of such cases; the cyst seemed to go into a sort of labour on its own account.

Dr. BANTOCK thought the case was one of tubal pregnancy, the tube giving way on its under surface, and that the fœtal sac had grown between the layers of the broad ligament.

Dr. CARTER related a case of extra-uterine pregnancy. The fœtus died about term, and was removed by abdominal section, though it could easily have been removed per vaginam, abdominal section being indicated by an abscess pointing at the navel. Labour-like pains were frequently observed.

Dr. EDIS advocated primary operation as an operation of election, especially in view of the present position of abdominal surgery.

Mr. GRIFFITH thought that the presence of a contractile cyst-wall necessitated the gestation being either interstitial or in an undeveloped form of a double uterus.

Dr. CHAMPNEYS observed that the uterine platysma which extended widely over the pelvic organs was sufficient to account for contractions, and that these occurred in undoubted extra-uterine pregnancies.

Dr. GODSON alluded to a case under Dr. Duncan, in which unsuccessful attempts had been made to kill the fœtus by morphia injections.

Case of Cystic Degeneration of the Cervix Uteri.

The PRESIDENT described this case. The patient, aged 45, had had nine children, the youngest five years old. The menopause had occurred three or four years previously to her admission, which was indicated by abdominal enlargement, which turned out to be due to obesity. The cervix was covered with close-set, tense, glistening vesicles, varying in size from a millet to a hemp seed. There was no other abnormal appearance, and there were no uterine symptoms whatever, the vaginal examination having been indicated by the abdominal enlargement. On puncture, nothing but air escaped with an audible sound, the vesicle so punctured afterwards being indistinguishable except for slight traces of the marks of the punctures.

Dr. HERMAN referred to the disease of the vagina and cervix, described by Winchel as "colpohyperplasia cystica," characterised by cysts containing air or gas.

(The following remarks of Dr. BARNES on Dr. KILNER'S paper were accidentally omitted from the report of the last meeting.)

Dr. BARNES had found Faradism capable of initiating as well as intensifying uterine contractions; but he had discontinued its use, partly on account of the pain it produced. Its power of lowering arterial tension might relieve the vomiting of pregnancy and other cognate disorders.

EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, MAY 14th, 1884.

NORMAN CHEVERS, M.D., C.I.E., President, in the Chair.

On the Colonization of the Sub-Himalayahs, with Remarks on the Management of European Children in India.

DR. JOSEPH EWART read a paper on this subject. In the sanitary and ethnological history of the plains of British India, he remarked, there is one fact which stands forth with conspicuous prominence, viz., the absolute powerlessness of Europeans to thrive and continue their race through many successive generations. Twining declared that there was no known instance in his time of a pure European descent in the country extending beyond the third remove, and Sir Joseph Fayrer's observation prolongs it to the fourth generation only, and no further. Although the effects of climate can be much mitigated by hygiene and sanitation for adults and children, anything like colonization, such as we have seen and now see going on in other lands, is totally impracticable. This truth is noted in the degeneracy of our race wherever it has attempted to settle down in the plains. Hence the wisdom of frequent change to the hills, or to Europe, for adults, and early transfer of children to England for physical training and intellectual education. Hence the necessity, too, for frequent change of the European troops to this country; for, although the effects of prolonged residence may be mitigated by increasing knowledge of the means to be used to withstand the climate and its ailments, there is no such thing as real or permanent acclimatization for the European. But is it so in those hill climates sufficiently elevated to be on the whole free from malaria, and temperate enough to render outdoor labour on the part of the European tolerable, healthy, and even

pleasant? The benefits received by adults who periodically visit the hills, which, except in the case of those who are the subjects of visceral disease, are signal and decisive, and by children, if kept long enough there, seem to point to an affirmative answer. Moreover, the results of the education of children at the Lawrence Asylums at Ootacamund, Abu, Sanawar, and Murree, are really not unfavourable. Hitherto the hills have been mainly used as temporary resorts to restore health, or overcome the ills and enervating effects of residence in the comparatively unhealthy and malarious provinces of the plains, and, in a few cases, by retired officers. As far as a judgment can be formed from the temperate character of their climates, their freedom from malaria and epidemics, their marked beneficial influence in preserving the health of European men, women, and children, and in contributing to its restoration in those suffering from functional disorders of climatic origin, the inference is that, if undertaken in suitable places, the colonization of the hills is probably not impracticable.

The second division of the paper was devoted to a practical review of the best means for the management of infants and young children in India. That most of the high mortality is preventible is clearly demonstrated. But when all that science and art can do has been done, it is painful to note among children in the plains, even those of the well-to-do, notwithstanding the advantages of an open air life—for they are reared in roomy mansions, always pervaded by constant relays of fresh air—the best nursing and medical care, and immunity from several of the infantile maladies so fatal in temperate climates, that they seldom present the all-round physiological tone, physical robustness, "muscular rotundity, hardness, plumpness, and rosy complexions" of children similarly circumstanced in this country. For all who can afford it, children should not be kept in the plains beyond the fifth or sixth year. A question of some moment is often put to us. Should European children born in England be taken to India? If suckling they may be for a time; but it would be better to have the process completed at home, and then to leave them here under proper custody, unless provision can be made for their passing the hot, rainy, and autumnal seasons, or what is still better, the whole of the ante-educational period of childhood, in the hills.

In the discussion which followed, The PRESIDENT, Drs. MOORE, PRINGLE, MAIR, CULLIMORE, AND WHITE, Surgeon-General MURRAY and Rev. J. LONG took part.

Dr. PRINGLE gave very favourable accounts of the subsequent careers of many of the boys educated in the Lawrence Schools, one of whom is now a F.R.S., while the four sons of another, whose father had been a private soldier, have obtained good positions in the Indian services, by competitive examinations, but Drs. Pringle and Murray were of opinion that the physical characters of the hill districts presented insuperable obstacles to colonization, the only arable soil being in the form of narrow ledges, and all really available for cultivation being already occupied by natives.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, APRIL 4TH, 1884.

DR. THUDICHUM, President, in the Chair.

The Treatment of Talipes.

MR. NOBLE SMITH was convinced that in every case of talipes, in which the tendons were tense and resistant, the sooner tenotomy was performed the better. The position in which the foot should be placed after tenotomy was important. If placed too near the original position of deformity, leaving the elongation of the tendon to the process of stretching, a great risk was run of contraction—a condition much more difficult to cure than when the deformity was treated for the first time. Upon the other hand, if the cut ends of the tendon were separated too much, and pressure applied on the part between the ends, there was danger of non-union—a serious misfortune. He described a case in which the tendo-Achillis had been divided for talipes-equinus; the foot had been fully extended and encased in a plaster of Paris bandage, and kept there for several weeks. The tendon had not united, and a severe form of talipes calcaneus had resulted. He found it advisable in the majority of cases to place the foot in a nearly normal position, leaving very little to be done by stretching. Many cases could be cured without operation, and plaster of Paris bandages could be used with benefit in some instances. He advocated simplicity with regard to construction of instruments for club-feet, and urged surgeons to give more attention to the details of construction, and to leave less to the discretion of the instrument-makers than they were generally inclined to do.

Dr. SINCLAIR THOMSON recommended the removal of a V-shaped piece of bone in varus, as a friend of his, in Germany, who adopted this plan in young children, and tied the bones together with catgut, had found it very successful.

Dr. THUDICHUM had noticed many cases of syphilitic brain disease in young persons, in which contraction of the plantar faciæ took place to a great degree, and he found them yield to anti-syphilitic treatment without operation.

Mr. BENHAM considered it a settled point in orthopædic surgery, that in cases of equino-varus, the varus should be first cured.

In reply, Mr. NOBLE SMITH said he would rather not perform osteotomy if the cases could be otherwise cured. With regard to performing the operation for equino-varus in two parts, he had often seen all the tendons cut at one operation, and generally with bad results. In his opinion, no operation should be undertaken where nervous symptoms, such as spasm, were present, until those symptoms had first been arrested.

Abscess of Kidney.

Dr. H. CAMPBELL-POPE showed specimens of diseased kidneys. The patient was said to have had no kidney symptoms during life, except frequency of micturition, and she suffered from violent headaches. She died suddenly, and at the *post-mortem* examination it was found that the pelvis of the right kidney was very largely dilated; while the left kidney had several large abscesses, which contained nearly a pint of curdy pus, together with a small stone. The cause of death was found to be hæmorrhage into the brain.

Suppurative Inflammation of Knee-joint.

Mr. J. R. LUNN showed a case of pus in the left knee-joint, which he had opened antiseptically, with a good result. The history was as follows:—J. E., aged 45, a shoeblack by trade, admitted into St. Marylebone Infirmary 1st November, 1883. He stated that he had never had any serious illness, except that when a child he had something the matter with his right hip. He had been ill seven days with intense pain in the left knee, which, on admission, was swollen and very hot. Distinct fluctuation was felt. It was treated with a back splint, leeches, &c. On the 7th it was aspirated, and 3 ozs. of pus withdrawn. On the 8th, the joint was opened under the spray, and a large-size drainage tube passed from the highest point of the joint, and a counter-opening made on the outer side of the joint. The joint was washed out with carbolic-lotion, 1 in 40, and dressed antiseptically, and the leg was put up in a McIntyre splint. That evening the temperature was 99·8°. The patient had slight rise of temperature every evening, and on the 22nd it went up 101°, when an abscess was opened on the outside of the joint. From this date the patient made an uninterrupted recovery; the antiseptics were left off on 11th December (five weeks and four days from the time of operation). The wound was dressed with a little iodoform, and the knee was put up in a plaster of Paris splint, which he kept on for about two

months, and the patient was able to get about in the ward. He was discharged 14th March cured, with a very fair movable joint. During the whole of the after treatment, he had only had nine dressings under the spray. On the 28th March, Mr. Lunn had seen this patient, since his discharge from the infirmary, and his statement was "that he gets about as well as ever."

INTERNATIONAL HEALTH EXHIBITION.

Article IV.

Dwellings.

Models and plans of dwellings are scattered in various parts of the Exhibition; some are near the main entrance, others in the grounds, and others again in the central gallery, Class XX. It seems a pity that the excellent classification which the Council designed could not have been more rigidly adhered to in practice. A medical *confrère* in search of a particular model wandered for two hours from gallery to gallery before his industry was rewarded. It is impossible at the present time to compare plans of rival artisan schemes without traversing and retraversing the considerable distance between the central gallery and the main entrance.

The various exhibits which illustrate methods of housing the poor, may be divided into those which are actual, that is, already built, and those that are prospective. Of the former, Mr. Edward Clarke contributes drawings of the industrial dwellings erected in Little Wild Street, White Hart Street, and Stanhope Street, Drury Lane; Leather Lane, Holborn; Turnmill Street, Farringdon Road; Queen Street, Seven Dials; Hanbury Street and Wellington Street, Whitechapel; and Lambeth Walk, Southwark. The plans and drawings of these tiers of ugly artisans' barracks must be studied in the entrance, or better still in the streets named, where they occupy areas formerly condemned with all the alliterative d's of dirt, disease, drunkenness, despair and early death. Improvements of this kind have their drawbacks. There was material for a Hogarth or a Doré in old Drury Lane, but what is there in the new save the repulsiveness of poverty, with none of its picturesqueness? The utilitarian deformity which for the last twenty years has reigned supreme as the guiding principle of model dwelling construction, has in its health results somewhat disappointed expectation. The zymotic rate of sickness in the St. Giles' new dwellings is scarcely inferior to that of the old. Typhus must be excepted, it is true; this subtle, malignant fever was formerly endemic in that parish, but now it is not more frequent in proportion amongst the St. Giles' poor than in the other Metropolitan districts. This happy change is attributable to the demolition of the fever-sodden tenements, the displacement of a great many of the Irish, and the substitution of new dwellings inhabited by new peoples.

The Metropolitan Railway Company exhibit an elaborate and highly finished model of prospective industrial dwellings to be built on the area cleared by the construction of the Tower Hill Extension Railway. The design is that of many storied tenements, so built as to enclose two quadrangles; thus, a larger number of windows and rooms will look out on a space enclosed by brick and mortar, than on to streets or houses. This to our mind is a cardinal, a fatal defect. There will be, as it were, two immense high flues, honeycombed, with windows; should typhus, diphtheria, or summer diarrhœa, prevail in the lower rooms, the up-current will almost certainly carry the particulate elements of infection to the upper rooms. We must strongly express our decided objection to all buildings of the block plan, built on a design which precludes free and thorough ventilation.

No. 388, in Class XX., is the joint exhibit of A. Wynter Blyth, the Medical Officer of Health for Marylebone, and Richard Greene, Medical Superintendent of Berrywood Asylum. It consists of models and plans for dealing with the poorest classes; and it is, we believe, the only exhibit which in any degree recognises the pressing need of providing for those who can only afford to pay low rents. The scheme consists in the construction of a block of buildings which in itself is to be a sort of compact city. Each family occupying one room, the sexes are separated at night, there are arrangements for ventilation, facilities for personal cleanliness, for washing linen, for prevention of fire, for escape from fire, provision for the infectious sick, and even a place which will serve as a temporary mortuary for the deposition of the dead.

If this scheme should ever come into practical operation, the authors recommend as a site a plot of about 110 feet long and 45 feet wide; this would afford ground space for a large block of five divisions, each division accommodating 20 families, or the entire block would make provision for 80 large families, 20 married couples without children, and 20 single people; in all, for 200 adults and 320 children.

How it is proposed to construct a single room for a family may be gathered from the following brief description. The dimensions of any of the larger rooms are to be 20 feet long, 12 feet wide, and 8 feet high; total cubic capacity 1,920 cubic feet. Ventilation is provided for by means of Tobin's tubes and special gratings, besides the windows, doors, and fireplaces. There are trucks of sheet iron for coal, and cupboards for general domestic storage. The main novel feature is in the construction of the bedsteads. Three brick piers project from one of the walls of the room, and form recesses about 18 inches deep. In these recesses are placed iron bedsteads; the head of the bedstead is clamped securely to the wall; about 14 inches from this head is a hinge joint, enabling the bedsteads to be easily folded up, the legs, &c., being so constructed as to facilitate this arrangement. The bedstead, on being thus folded up close to the wall with its bedding, is covered and concealed by partitions; and the whole is so arranged that at night the partitions partially divide the room into three compartments, whilst by day a visitor would see neither beds nor bedding, but a clear floor space as in an ordinary sitting-room. There is a simple provision for the ventilation of the bedding thus placed out of sight; and by cutting apertures into the lower edge of the partitions and not carrying them quite up to the ceiling the little compartments are at night well-ventilated. The authors consider that by this plan the tenants will have the comfort of a convenient sitting-room during the day, will be able to cleanse the floor much more easily than if it were covered with furniture, and will also be able to dress, undress, and sleep with decency. The basement is to be used as a laundry, and on the landing is a lavatory and sink for two families.

At the top of the building, on the roof, is placed a small hospital; here women may be confined, or infectious diseases isolated. There are many other details relative to escape in case of fire, &c., which may be studied on the plans and models themselves. Of course it would be necessary to appoint a *concierge*, and we should imagine the success of the scheme would mainly depend on the extent and kind of supervision the dwellings when built and occupied would receive.

Another novel proposal is that of Mr. O'Keefe, who shows models of tower-like houses which he would construct at the corners of important thoroughfares, connected with each other by light foot bridges, available for escape in case of fire, and also to facilitate the passage of foot passengers over dangerous crossings. With regard to the latter, we certainly think that subways would be better; any bridge would have to be built such a height that the labour of going up and down each staircase would be onerous; whereas a subway could be made comparatively shallow, and if properly lit, such methods of cross communication would be of great public convenience and diminish street accidents. Both Messrs. C. B. and A. H. Allen, of Chelsea, exhibit some models of cottages (Class XX., 394 and 393). In a miner's cottage, the form is not devoid of neatness and beauty; the most noteworthy internal improvement is keeping the fire-places or means of heat in the centre of the building, so that the warmth of the household hearth is not radiated away by the external walls. A

labourer's cottage, designed by Mr. A. H. Allen, suggests the substitution of partitions of wood quartering, coated with silicate paint and filled in with slate panels, instead of the ordinary combustible material.

A model, which has attracted some attention, is that exhibited by Lieut.-Col. J. R. Turnbull (Class XX., 391); the drains instead of being buried in the earth are laid in an open channel, so that they are at all times ready for inspection. Considering the injury to health and the expense of defective drains which are placed so carefully out of sight that some one has to be ill of fever, or grievously distressed by a nuisance, before any investigation is likely to be undertaken: this proposal seems to possess many and great advantages. A somewhat similar idea is exhibited by Mr. Nicoll in a model in the South Annexe (Class XXII., 424.) In this each street is supposed to have a subway, in which run sewers, telephone wires, gas tubes, &c.; beside which the sewage is intercepted in an ingenious manner, and there is no direct connection between the house drain and sewer. There is not the slightest doubt that if a new city is ever built, very extensive subways, if not indeed underground roads for heavy traffic, with the cellars and stores of shops opening on to such subterraneous passages would be constructed, the convenience of such an arrangement being obvious. As it is, some modification of Mr. Nicoll's plan may have to be adopted, especially if, after a few more people have been decapitated by the over-head wires, an Act be passed to run the wires where they ought to be, under the surface.

GENERAL CORRESPONDENCE.

VEGETARIANISM AT THE HEALTH EXHIBITION.

[To the Editor of the Medical Times.]

SIR,—The truly "impartial and scientific manner" of your approach to the study of "practical vegetarianism" is so grateful to the Executive of the Vegetarian Society, that I am encouraged to ask you to permit me to submit some corrections of your figures.

As the Chairman of the London Committee of the Society, I have asked our manager for a copy of the statement of quantities furnished to you, and I find that bread and potatoes, of an approximate gross weight of 2,600 ozs., are omitted from the list. The bread is whole meal. I also learn, that of the 440 persons mentioned by you, only 390 partook of the "sixpenny dinner."

If I had before me your method of arriving at the dry weight (which I judge your quotations to represent), I would follow up the calculation and correct your final averages: in default, I can only ask you to be so good as to apply the added weight and diminished number to your previous totals, and in the interests of "scientific" truth to quote, in your next issue, the results in bulk, and cost per person (I do not expect to find that our sixpenny dinner is costing us less than 3½*d.*, or including condiments 4*d.*), when not only will the nutritive quality of our supplies be more apparent, but our liberality, at least, will be a little more justly conspicuous than under an allegation of cost of twopence.

I am, Sir, yours, &c.,
SANDYS BRITTON.

Vegetarian Restaurant,
13, *Rathbone Place, Oxford Street, W.*

[The writer of the article calculated the dietary from the list drawn out expressly for that purpose by the manager; if the manager furnished an inaccurate list, the writer does not feel inclined to again go through laborious calculations to possibly be met with a like objection. If, however, the Vegetarian Society choose to arrange for all the substances eaten on a particular day to be weighed and measured under scientific supervision, we may, on account of the general interest of the subject, again refer to it.

ED. *Medical Times.*]

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS.

AT a meeting of the Royal College of Physicians, held on the 29th instant, the following communications were presented:—A Gracious Acknowledgment from Her Majesty, in reply to the Address of Condolence on the Death of the Duke of Albany, and a letter of thanks from Her Royal Highness the Duchess of Albany; a letter from Rome, proposing that the College should assist in erecting a Statue to Fabricius; a letter from the Poor Law Medical Officers' Association, asking the assistance of the College to obtain an amendment of the Poor-Law Medical Officers' Superannuation Act, so as to make it compulsory instead of permissive, and one from the Royal College of Surgeons of England as to the importance of obtaining an amendment of the clause in the Medical Act Amendment Bill dealing with surplus funds of the Medical Board. Referred to the Medical Bill Committee.

Licenses to practise were granted to three candidates who had passed the required examinations.

The certificate of his having gained the Murchison Scholarship of the year was presented to Mr. J. Bland Sutton.

A list of Members of the College who had been nominated for the Fellowship was referred back to the Council for reconsideration and revision.

Dr. Dyce Duckworth was elected treasurer to the College, in the room of the late Dr. Andrew Whyte Barclay.

The new by-laws, providing for the appointment annually of two Fellows to be Vice-Presidents of the College, were enacted for the first time.

A lengthy report was received from the Committee on Nomenclature of Diseases, stating that the process of revising the work, which had been commenced in 1880, was now completed; referring to some special changes made in it; and recommending the special thanks of the College should be given to certain gentlemen named. The report was adopted.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners on the 22nd instant, and when eligible will be admitted to the pass examination, viz.:—

Messrs. Edward B. Ormerod, Charles P. White, and Arthur R. Down, Students of St. Bartholomew's Hospital; Arthur Crossley, Peter Paget, and Arthur E. Palmer, of Guy's Hospital; William J. Oliver, and Samuel G. Moores, of St. Thomas's Hospital; George H. Seagrave, and Arthur E. Paul, of University College Hospital; Herbert P. Prankerd, of the Westminster Hospital; Hugh Exton, of the London Hospital; and William G. Bower, of King's College Hospital.

Thirteen candidates having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their Anatomical and Physiological studies for three months, and two for six months.

The following gentlemen passed on the 23rd instant, viz.:—

Messrs. William J. Rogers, Percy G. Gilmore, and George A. Edsell, of St. Bartholomew's Hospital; William T. Rayne, of the Westminster Hospital; Walter L. Wyatt, of the Middlesex Hospital; Arthur T. Brown, of Guy's Hospital; Walter H. Moyle, and Thomas C. Summers, of the London Hospital; Albert C. Lewis, of University College Hospital; and William B. Wedgwood of King's College Hospital.

Ten candidates were referred for three months and four for six months. One hundred and forty-eight candidates presented themselves for the examination just completed, as compared with 169 at the corresponding period of last

year; of this number 69, having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their Anatomical and Physiological studies for three months, and eight for six months; making a total of 77 referred candidates.

The half-yearly primary or Anatomical and Physiological examination for the Fellowship of the College was commenced on the 23rd instant, when 90 candidates presented themselves.

At the oral examination on the 24th and 26th instant, the following gentlemen were reported to have acquitted themselves to the satisfaction of the Board of Examiners, and when eligible will be admitted to the pass examination, viz. :—

Messrs. Herbert Lund and W. H. Jessop, of the Cambridge School; Thomas Sinclair, of the Belfast School; W. G. Richardson, of the Newcastle School; Herbert Herbert, of the Leeds School; R. T. C. Leith, of the Edinburgh School; P. M. O'Brien, of the Liverpool School; P. B. Connolly, of the Charing Cross Hospital; E. T. Thring, of the University College Hospital; Arthur Hardwick, of the Westminster Hospital; R. F. Jowers, of St. Bartholomew's Hospital; Henry Hyde, of King's College Hospital; and H. C. Bowman, of the Manchester School.

Nineteen candidates having failed to acquit themselves to the satisfaction of the Board of Examiners were referred to their Anatomical and Physiological studies for six months.

The following gentlemen passed on the 27th instant, viz. :—

Messrs. John Richards, F. C. Bury, and A. H. Smith, of the Manchester School; W. W. C. Robson, and Robert Nairn, of St. Thomas's Hospital; J. W. Barrett, University of Melbourne; L. J. Pisani, Charing Cross Hospital; J. R. Bradford, University College Hospital; and E. F. White, King's College Hospital.

Eleven were referred for six months.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 22nd, 1884:—

Charles Harry East, The Limes, Kettering, Northamptonshire; Thomas George Jeffs Lavers, 69, Clarendon Road, W; Leonard Roberts, Bishops, Lydeard; William Henry Tomlins, 25, Rutland Street, Hampstead Road; James Wilding, 3, Lambourne Road, Clapham.

The following gentleman also on the same day passed the Primary Professional Examination.

Arthur Shaw, University College Hospital.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners, held on the 8th May and following days, the under-named gentlemen passed their final examination for the letters testimonial of the College, and having taken the declaration and signed the roll, were admitted licentiates, viz:—

Berkeley J. Acheson, George H. Bagot, Louis A. F. Bate, John Bernal, Francis L. Carte, James V. Collins, Cecil Cronin, Thomas Crow, Alexander Cuffe, Thomas J. Daly, Julius Barry Delaney, Thomas L. Dillon, Cuthbert Eccles, Patrick J. Ford, Frederick J. Greig, James Hanna, Denis Kennedy, Graham Kennedy, Charles R. Kilkelly, Benjamin Lane, Frederick D. Lawson, John Lowney, Edward M'Nulty, Thomas J. M'Grath, James H. Maguire, Edward L. Minchin, Cornelius R. Moloney, Walter A. Murray, Llewellyn T. M. Nash, Charles J. Perrott, William W. Scott, Edward N. Smartt, Alexander Stewart, Malcolm E. Thomson, Augustus M. Westropp, Henry E. P. Wright, Thomas N. Wright, John H. Woods, and John F. Yates, Esquires.

Thirteen were referred to their studies.

Cambridge University.—The following corrected programme of Examination for Medical and Surgical Degrees in the Easter Term, 1884, has just been issued. First Examination for Degree of Bachelor of Medicine:—Friday, June 6th: 9 a.m. to 12.0. Elementary Biology. 1.30 p.m. Oral and Practical Examination in Elementary Biology. Saturday, June 7th: 9 a.m. Oral and Practical Examination in Elementary Biology. Monday, June 9th: 9 a.m. to 12.0. Chemistry. 1.30 to 4 p.m. Mechanics and Hydrostatics. Tuesday, June 10th: 9 a.m. to 12.0. Heat, Electricity, and Optics, 1.30 p.m. Practical Chemistry (in the University Laboratory) and Oral Examination. Wednesday, June 11th: 9 a.m. Practical Chemistry (in the University Laboratory) and Oral Examination. Second Examination:—Tuesday, June 10th: 9 a.m. to 12.0. Physiology (in the Physiological Laboratory), 2 to 4 p.m. Pharmacy and Pharmaceutical Chemistry. Wednesday, June 11th: 9 a.m. to 12.0. Human Anatomy, 2 p.m. Oral Examination in Pharmacy. Thursday, June 12th: 9 a.m. Oral and Practical Examination in Physiology (in the Physiological Laboratory). Friday, June 13th: 9 a.m. Oral Examination and Dissection (in the Anatomical School). Saturday, June 14th: 9 a.m. Oral Examination and Dissection (in the Anatomical School).

Aberdeen University Club, London.—The inaugural dinner of the newly-formed Aberdeen University Club was held in the Venetian Salon of the Holborn Restaurant, on Wednesday, the 21st, the President, His Grace the Duke of Richmond and Gordon, in the chair. There was a large attendance—about 160—including, Lord Watson, Sir Herbert Maxwell, Sir Andrew Clark, Sir Wm. Guyer Hunter, Sir Wm. MacCormac, Dr. J. Matthews Duncan, A. Bain, LL.D. (Lord Rector of the University), J. A. Campbell, LL.D., M.P., Mr. Farley Leith, Q.C. After the usual loyal toasts, the chairman proposed the toast of the evening—"Prosperity to the Aberdeen University Club, London." Dr. Campbell proposed the University, and Dr. Bain replied. The chairman's health was proposed by Sir H. Maxwell, and that of the Hon. Secs., Dr. R. W. Burnet and Mr. R. W. Routledge, by Sir Andrew Clark. Excellent music was supplied by the Bijou Drawing-room Orchestra Company, and songs were given by Dr. Glover, Mr. Cantlie, and others.

Extraordinary Case of Poisoning at Glasgow.—On Sunday afternoon it was reported to the police of the Western district, that a whole family, consisting of a man, his wife and four children (the latter aged respectively 18 years, 8 years, 6 years, and an infant aged 11 months) had become seriously ill after partaking of some curds and cream, obtained from a dairy in the neighbourhood on Saturday afternoon. It is stated that the curds and cream were eaten shortly after two o'clock on Saturday afternoon, and that about 6 p.m. of the same day they became ill, suffering from vomiting and severe internal pains. The infant suffered apparently as much as the others, although only two spoonfuls had been taken. A medical man was called in who did what he could and so far successfully that he was able to give it as his opinion that the sufferers were out of danger on Sunday morning, before he left them. The police, having taken the matter in hand, discovered that the milk from which the curds were prepared had been obtained from a dairyman in another part of the city. A portion of the milk as well as part of the curds and cream found in the shop were secured by the police and forwarded to Professor Dittmar, Anderson's College, for analysis. It is supposed that the poisonous matter may be discovered in the preparation used for curdling the milk, but this is merely surmise, and until the report of Professor Dittmar is known, the extraordinary case must remain obscure. On Monday morning the man and his wife were still suffering from the effects of the poison, while the others had all recovered.

The Belfast Meeting of the British Medical Association.—The *Irish Times* is informed that it is more than probable that the Dublin Medical faculty will as a body abstain from attending the forthcoming meeting of the British Medical Association at Belfast, owing to the action of the Local Committee in making arrangements whereby it is felt the position of the Dublin practitioners has not been properly recognised. It is alleged that the Northern Capital has been putting itself in the post of honour to the exclusion of its guests. The working of the coming meeting has been placed in the hands of fifteen officers from Belfast and vicinity; seventeen from England; six from Scotland; while all the rest of Ireland—outside Belfast—is represented by only five.

Scholarships for Research.—At a Court of Assistants of the Worshipful Company of Grocers, held on Wednesday, May 21st, 1884, the following candidates were elected to the Company's Scholarships for Research into the causes of important diseases, viz.—(1) W. North (renewal)—subject, Ætiology of Ague; (2) Leonard C. Wooldridge, D Sc., M.B.—Hæmorrhagic Disease, Pernicious Anæmia, and Blood Clotting; (3) Alfred Lingard, M.R.C.S.—Intimate Ætiology of Enteric Fever.

Army Medical Department.—Inspector-General J. Mure, M.D., on the Retired List, died at 40, Tedworth Square, on the 16th instant. He entered the service

October 4th, 1839; became surgeon, December 24th, 1847; surgeon-major, July 6th, 1855; deputy-inspector-general, August 7th, 1867; and retired, with the rank of inspector-general, December 1st, 1869.

DEATHS FROM EATING TINNED SALMON.—Two deaths have just occurred at Wolverhampton, with symptoms resembling those of cholera, ascribed to the effect of eating tinned salmon. The medical attendants believe that the poison which proved fatal was not a metallic, but an animal poison. The contents of the stomachs of the victims, together with the remainder of the salmon, and a full tin of salmon of the same brand are to be submitted to analysis.

CAMBRIDGE PHILOSOPHICAL SOCIETY.—At the last meeting of this Society, the following were elected honorary members:—Dr. Anton Dohrn, of Naples; Professor Gegenbaur, of Heidelberg; Professor Pflüger, of Bonn; Mr. W. T. Thiselton Dyer, and Mr. J. Whitaker Hulke.

WESTMINSTER HOSPITAL.—At a meeting of the House Committee, held on May 27th, a Building Committee was appointed for the purpose of making arrangements for the erection of a medicine school, on the site already purchased in Caxton Street.

PROPOSED NEW SMALL-POX HOSPITAL.—The Managers of the Metropolitan Asylums District have applied for the consent of the Local Government Board to the erection of a hospital for small-pox patients at Gore Farm Estate, Essex, at a cost of 120,000*l.*

THE APOTHECARIES' SOCIETY.—The first open surgical scholarship of the Society of Apothecaries of London has been awarded to Sidney Plowman, St. Thomas's Hospital.

APPOINTMENTS.

BOYD, S., M.B.—Surgeon to the Paddington Green Children's Hospital.

BROWN, J. MACDONALD, M.B., C.M. Edin., F.R.C.S. Eng. and Edin.—Lecturer on Anatomy at the Surgeons Hall School of Medicine, Edinburgh.

CAIGER, F. F., M.B., M.S., M.R.C.S., L.R.C.P., Exten.—House Surgeon to St. Thomas's Hospital.

COOPER, G. F., M.R.C.S., L.R.C.P., Completion of Term.—House Surgeon to St. Thomas's Hospital.

GLASSINGTON, —, M.R.C.S.—Anæsthetist to the National Dental Hospital.

GREEN, C. D., M.R.C.S., L.R.C.P., Exten.—Resident House Physician to St. Thomas's Hospital.

HART, DAVID BERRY, M.D.—Assistant Physician to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

HEARD, CHARLES DE WOLFE, L.R.C.P. and L.R.C.S. Edin.—Medical Officer for the Keelby District of the Caistor Union, *vice* Mr. A. Allen, resigned.

HEBBERT, C. A., M.R.C.P. Lond.—Demonstrator of Anatomy in the Westminster Hospital Medical School.

HEWITT, F. W., M.B., M.R.C.S.—Anæsthetist to the National Dental Hospital.

HUGGARD, W. R., M.D.—Assistant Physician to the West End Hospital, 73, Welbeck Street, *vice* H. Tibbits, M.D., resigned.

HULL, WATTER, M.B., M.R.C.S., L.R.C.P., Exten.—Resident House Physician to St. Thomas's Hospital.

JOHNSTON, G. D., M.R.C.S., L.R.C.P., Completion of Term.—House Surgeon to St. Thomas's Hospital.

JONES, H. L., M.R.C.S.—Assistant House-Surgeon to the St. Bartholomew's Hospital, Chatham, *vice* G. Welch, L.R.C.P., resigned.

LYON, T. GLOVER, M.R.C.S., L.R.C.P.—Clinical Assistant in the Skin Department of St. Thomas's Hospital.

MACDONALD, J., M.B.—Junior House-Surgeon to the Carlisle Dispensary, *vice* W. M. Storrar, M.B., resigned.

MORRISON, J. T. J., M.B.—Resident Surgical Officer to the General Hospital, Birmingham, *vice* H. G. Barling, M.B.

NIAS, J. B., M.B.—Honorary Physician to the Western General Dispensary.

ORFORD, JOHN, M.R.C.S., L.R.C.P.—Resident Accoucheur to St. Thomas's Hospital.

ROBINSON, H. B., M.R.C.S., L.R.C.P.—Assistant House Surgeon to St. Thomas's Hospital.

SANEYOSKI, Y., M.R.C.S., L.R.C.P.—Assistant House Physician to St. Thomas's Hospital.

SCUTT, T., M.R.C.S., L.R.C.P.—Assistant House Physician to St. Thomas's Hospital.

SMITH, JAMES MURRAY, M.B. and M.C. Aberdeen.—Medical Officer for the First District of the Romford Union, *vice* Mr. A. Wright, resigned.

STONE, F. W. S., M.R.C.S., L.R.C.P.—Non-Resident House Physician to St. Thomas's Hospital.

SUTTON, H. M., M.R.C.S.—Junior Resident Medical Officer to the Great Northern Central Hospital, *vice* N. B. Gandevia, M.R.C.S.

SUTTON, S. W., M.D., B.S., &c.—Ophthalmic Assistant to St. Thomas's Hospital.

TILLEY, W. J., M.R.C.S.—Assistant House Surgeon to the Devonshire Hospital, Buxton, *vice* A. C. Buist, M.B.

TYRRELL, WALTER, L.R.C.P., M.R.C.S.—Anæsthetist to the National Dental Hospital.

UHTHOFF, J. C., M.D., F.R.C.S.—Assistant Surgeon to the Sussex County Hospital, *vice* H. Couling, F.R.C.S., resigned.

UNDERHILL, CHARLES E., M.D.—Assistant Physician to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

VACANCIES.

DENBIGHSHIRE INFIRMARY, DENBIGH.—House Surgeon. Salary to commence at £85 per annum, with board, residence and washing. Candidates must be duly qualified. Conversant with the Welsh language. Applications to be sent to the Secretary, on or before June 5th.

EAST SUSSEX, HASTINGS, AND ST. LEONARDS' INFIRMARY.—Assistant Physician. Candidates must be duly registered Doctors or Bachelors of Medicine of some University of Great Britain or Ireland, or Fellows or Members of the Royal College of Physicians of London, Edinburgh, or Dublin. Applications, with testimonials, to be sent to the Secretary, not later than 10 o'clock on the morning of June 10th, the day of election.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free, &c. Candidates names must appear upon the Medical Register as being possessed of a medical and surgical qualification, and they must produce evidence of good moral character. Private practice strictly prohibited. Applications, with testimonials, to be sent to the Secretary, on or before June 11th. The election to take place on June 18th.

GUEST HOSPITAL, DUDLEY.—Resident Medical Officer. Salary £120 per annum, with furnished residence, board, coal and gas. Candidates must be registered with a double qualification, and be unmarried. Applications, with testimonials, and certificates of registration, to be sent to Mr. E. Poole, Secretary, not later than June 4th.

MACHYNLLETH UNION.—Medical Officer to the Towyn District, in succession to Mr. John Ffoulkes Jones, deceased. Population, 3,358. Salary, £36.

NORTHAMPTON GENERAL INFIRMARY.—Surgeon. (*For particulars see Advertisement.*)

OWEN'S COLLEGE, MANCHESTER.—Lectureship. (*For particulars see Advertisement.*)

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Chair of Physiology. (*For particulars see Advertisement.*)

SUNDERLAND INFIRMARY.—Senior House Surgeon. Salary, £100 per annum, with board and residence. Candidates must possess double qualifications (registered). Applications, with testimonials, to be sent to the Chairman of the Medical Board, on or before June 2nd. The election will take place on June 12th.

WINDSOR ROYAL INFIRMARY.—House Surgeon. (*For particulars see Advertisement.*)

DEATHS.

ALDRED, H. A., M.D., of Westbourne Park, on May 21st.

DAVID, JOHN, M.D., at 16, Sydenham Villas, Cheltenham, on May 18th, aged 67.

MURIEL, JOHN, J.P., D.L., F.R.C.S., at the Palace Green, Ely, on May 26th, aged 85.

JONES, C. M., L.R.C.P., F.R.C.S., at 3, St. Andrew's Terrace, Plymouth, on May 16th, aged 49.

NOTES, QUERIES, AND REPLIES.

College of Surgeons, Primary Examination for the Fellowship.—The following were the questions submitted to the candidates at the written examination held on Friday, the 23rd instant:—

ANATOMY.—1. Give the dissection required to expose the complete dome of the pleura of the right side. 2. Describe the action of the muscles passing between the trunk and upper limb in reference to the movements of the shoulder-girdle and arm upon the trunk. 3. Describe fully the twelfth dorsal vertebra, mentioning the various structures attached to it. 4. Describe the dissection required to expose the transversus pedis muscle.

PHYSIOLOGY.—1. What are the distinctive Functional and Structural characters of Animal and Vegetable Cells? Give the evidence on which your statements rest. 2. Describe the means by which a Muscle-curve is obtained. What circumstances modify the contraction of Muscle, and the form of the Muscle-curve? 3. Assuming the right fore-arm to have been voluntarily flexed, describe the course of the Nerve-impulse by which this movement was excited, from the cerebral Motor Ganglion-cells to its exit from the Cord. Give the evidence on which your answer is based. 4. Describe the Mechanisms by which Accommodation is accomplished, and the methods of accurately determining them.

APPOINTMENTS FOR THE WEEK.

Friday, May 30 (*this day*).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m.—M. E. Mascart, "Sur les Couleurs."

Saturday, May 31.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL INSTITUTION, 3 p.m.—Professor Bonney, "Microscopical Geology."

Monday, June 2.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

ROYAL INSTITUTION, 5 p.m.—General Monthly Meeting.

Tuesday, June 3.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

ROYAL INSTITUTION, 3 p.m.—Prof. Gamgee, "Nerve and Muscle."

Wednesday, June 4.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

OBSTETRICAL SOCIETY OF LONDON, 8 p.m.—Specimens will be shown by Dr. Godson, Dr. Galabin, Dr. Aveling, Dr. Walters, Dr. Malins, Dr. John Williams, and Dr. R. Barnes. Papers will be read by—Dr. Playfair, "Note on the Absorption, with ultimate Recovery, of Thrombosis of the Pulmonary Artery in the Puerperal State;" Dr. Matthews Duncan, "On Fœtal Revolutions;" Dr. Lediard, "Fibro-cystic Myoma of Uterus."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Edward Albert Schäfer, F.R.S., "The Functions of the Marginal Convolution."

Thursday, June 5.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Living and Card Specimens at 8 p.m.—Dr. P. H. Mules, "Drawing of Fundus with choroidal Tubercles: stained Sections of tuberculous Choroid;" Dr. Brailey, (1) "Paralysis of external Rectus and Mydriasis, with a recent history of Uni-ocular Diplopia," (2) "Sympathetic Papillitis;" Messrs. Critchett and Juler, "Case of Choroiditis Disseminata;" Messrs. Cowell and Juler, "Mounted Specimens of Intra-ocular Sarcoma." Communications at 8.30 p.m.—Dr. Sharkey and Mr. J. B. Lawford, "Optic Neuritis, associated with acute Myelitis;" Mr. Nettleship, (1) "Cases of Recovery from Amaurosis in Infants," (2) Case of Retro-ocular Neuritis;" Dr. C. E. Fitzgerald, "An Instrument for showing the Action of the Accommodation;" Mr. J. B. Lawford, "Amblyopia with Contraction of visual Fields and central Scotoma, ending in Recovery;" Mr. Adams Frost, "Ciliary Staphyloma, following Irido-choroiditis, sympathetic Ophthalmitis subsequent to Excision;" Mr. Simeon Snell, "Case of Uni-ocular Diplopia."

ROYAL INSTITUTION, 3 p.m.—Prof. Dewar, "Flame," &c.

Friday, June 6.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Edward Albert Schäfer, F.R.S., "The Analysis of Voluntary Muscular Action."

ROYAL INSTITUTION, 8 p.m.—Mr. Willoughby Smith, "Electric Induction Experiments."

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.

Physician to the Hospital.

Lecture II.

Catarrh of the Respiratory Passages—Acute Nasal Catarrh.

Gentlemen,—The treatment of diseases of the respiratory organs will form the first part of my course, and I shall commence to-day with the consideration of the treatment of catarrhal affections of the air passages.

The word "catarrh," which in recent times has acquired such a very wide application, had, originally, as its derivation indicates, a very restricted one. Derived from the Greek verb καταῤῥέω, to flow down, it was applied by the ancient physicians to that very common affection of the nasal passages, which we call a "cold in the head." The characteristic increased discharge, or flow of mucus from the nasal mucous membrane, they termed a "catarrh"—a *flowing down*, as they thought, of fluid from the brain; and the pituitary gland was believed to be a principal agent in the separation of this fluid, which was supposed to flow down through the sphenoid bone.

It was only towards the end of the sixteenth century that Schneider showed the erroneousness of this view, by proving the absence of any canals through which such a flow could take place, and maintained that it was due to an increased separation of fluid from the blood by the mucous membrane of the nose, henceforth termed the Schneiderian membrane.

This ancient belief is, however, still perpetuated in the common French expression, *rhume de cerveau*, for a cold in the head; and if you happen to sneeze in the waiting-room of a railway station in the South of Europe, you may, perhaps, be surprised to hear a peasant in your neighbourhood suddenly bestow upon you what is meant as a benediction. He intends to congratulate you on having got rid of something which may have been obscuring your mental faculties.

Nowadays a "catarrh" means an abnormal increase in the secretion of any mucous membrane, due to hyperæmia, or inflammation of the same. This inflammation may be *acute* or *chronic*, slight or severe, a mere passing irritation, or a more or less permanent malady. So that we now not only speak of *nasal*, *pharyngeal*, *laryngeal*, and *bronchial* catarrhs, but also of gastric, duodenal, and intestinal catarrhs, catarrh of the bile ducts, and also of vaginal, urethral, vesical, and uterine catarrhs; meaning in all these cases an inflammation (or hyperæmia) of a mucous membrane,

attended with an increase of, or a modification in, its natural secretion.

For the present we are only concerned with catarrhs of the respiratory mucous membrane, and first of all, we shall consider the occurrence and management of that very common and often distressing form of catarrh which is variously termed "coryza," "rhinitis," "nasal catarrh," or more commonly "cold in the head."

I need scarcely tell you that the lives of certain persons are troubled by a tendency to constantly "catch cold," as it is termed. I regret to say I am myself not free from this predisposition. But it is a curious fact that while some persons have a proneness to become afflicted with nasal catarrh, others will exhibit a tendency to pharyngeal catarrh, others to laryngeal, and others to bronchial catarrh. There are persons who are frequently the subjects of nasal catarrh, and even of laryngeal catarrh, but who never suffer from bronchial catarrh; and conversely, there are many who, although, frequently the victims of bronchial catarrh, never suffer from nasal or laryngeal catarrh.

In my own personal experience, I find a nasal catarrh will, if neglected at its onset, occasionally extend into the larynx; but it stops there, and has never yet extended lower along the respiratory passages. To antagonise this predisposition to catarrhs of the air passages, is an important consideration in their management. So also is the possibility of their spread by contagion.

It is a popular belief that "colds in the head" are catching! and it certainly is remarkable the way in which they run through families and households. Some account for this by assuming the existence of an "epidemic" influence associated with meteorological conditions, and no doubt these affections are at times epidemic, but they frequently occur and spread through families when their origin and extension cannot be so accounted for. Fraenkel remarks that he has often observed bridegrooms who have never before suffered from coryza, become attacked by this malady on marrying brides who have been prone to such attacks!

The chief cause of nasal as well as of other catarrhs of the air passages is no doubt the existence of an undue impressionability of certain portions of the surface of the body to even slight changes of temperature. Also the extreme excitability of the nasal mucous membrane in some persons to the contact of certain substances is a well known cause of catarrh. The pollen of grasses and other plants produce in some persons distressing attacks of so-called "summer catarrh" or "hay fever." The perfume of a rose has been known to have the same effect, and I have seen the most distressing attack brought on by turning over the leaves of a book that had long been undisturbed on the library shelves.

The treatment of acute nasal catarrh may be conveniently considered under three heads:

1. Prophylactic treatment.
2. General remedies.
3. Local remedies.

(1) *Prophylactic Treatment.*—The predisposition to suffer repeatedly from attacks of coryza may be greatly diminished by suitable prophylactic measures. The most important of these is the adoption of some hardening process which shall have for its object the removal or diminution of a certain hyper-sensitiveness of the skin and mucous membrane which characterises such patients.

Avoidance of sedentary habits and free exercise in the open air are of great value. Cold affusion over the head and neck, begun in warm weather and steadily maintained throughout the whole year, is of undoubted efficacy. The use of the *shower-bath* for this purpose has been strongly advocated, but there are not many persons who can tolerate a cold shower-bath all the year round, but most persons can bear two or three large spongefuls of cold water wrung out over the head and neck on first rising in the morning.

This process imparts contractile vigour and tone to the superficial vessels and counteracts the tendency to vascular dilations and hyperæmia, upon which catarrhal conditions mainly depend.

A tendency to nasal catarrh and to other catarrhal states is excited and maintained by residence in low-lying, damp, cold situations; and it is hopeless to endeavour to relieve, permanently, such conditions while the subjects of them continue to dwell in these localities. It follows that one of the best prophylactic measures against attacks of nasal catarrh is residence in a dry, bracing locality.

No measure is perhaps so efficacious, as a preventitive to such attacks, as a few weeks' residence in a high, open mountain valley like that of the Upper Inn in Switzerland. I have myself experienced this in a remarkable degree. The dry, cold, bracing air of this region seems to be of especial value in lessening the morbid sensitiveness of the surface, so far as it tends to the production of catarrh of the respiratory tracts. I believe it acts partly by causing contraction of the superficial vessels and increasing their tone. It is quite otherwise with respect to the tendency to suffer from rheumatic pains when exposed to atmospheric vicissitudes. In such cases the climate of the Engadine generally aggravates the rheumatic tendency; and this it probably does by checking cutaneous transpiration.

(I have entered fully into this subject in some of the chapters in my work on "Health Resorts and their Uses.")

Next in value to mountain air, as a prophylactic, is well-directed sea bathing, during the summer months, associated with abundant exposure to the open air of the seaside. Such patients should not be allowed to remain long in the sea at one time; it is better they should make repeated plunges, for it is the bracing shock to the surface that is required, not the continued contact of the cold sea-water. At Biarritz they have a plan of standing just ankle-deep, or but little more, in the sea, and allowing the Atlantic surf as it comes in to dash over them. One of the best natural douches that can be imagined.

Persons who suffer from summer catarrh or "hay fever," are often immediately relieved on removal to the sea coast.

This treatment of combined sea-bathing and sea-air is of the greatest value to scrofulous children, who frequently show a tendency to attacks of nasal catarrh, which sometimes become chronic, and give rise to much trouble; for chronic nasal catarrh in scrofulous subjects is a most obstinate malady, and one difficult to treat with success.

(2) Next with regard to *General Remedies.*—Of all the general remedies advocated for the cure of attacks of coryza, opium or morphine is by far the best.

I have again and again tested its value, and often in my own person; and if it fails to cure or cut short a cold in the head, it at any rate takes from it all its terrors!

Opium undoubtedly exercises a remarkable effect over the capillary circulation, especially in the respiratory mucous membrane, and I have often known a single dose of opium completely arrest a catarrhal fluxion from the nose, which, from its abundance, entirely prevented sleep, and this in fifteen or twenty minutes.

But it is by no means a matter of indifference what method you adopt in administering the opium.

When you are able to treat the cold quite in its initial stage, when the nasal mucous membrane is only a little swollen and dry, and there is an uneasy feeling

over the frontal sinuses, and before the occurrence of any great amount of fluxion, the following I believe to be the best method :—

Supposing the patient to have had a good meal in the middle of the day, no more solid food should be taken that day, but about three or four hours before bedtime an eighth of a grain of acetate or sulphate of morphine (I use McKesson and Robbins' pilules of this strength) should be taken with a small cup of weak tea ; and at bedtime another eighth of a grain with a wine-glassful of whisky and water.

This measure alone will constantly arrest a cold in the head if adopted in the initial stage ; and even when this stage is passed, it will relieve all the uncomfortable distressing feelings which attend these attacks.

Yet you will often find it fail ; but it fails because both patients and doctors will not attend to small details. If you do not caution your patient to the contrary, he will probably eat a heavy evening meal, following the old-fashioned maxim of "feeding a cold," and take his dose of morphine on a full stomach. Now it makes all the difference in the world whether this small dose of morphine be absorbed into the blood in a few minutes, or whether it be mixed with a mass of food and absorbed slowly with it after some hours.

The result in the two cases is wholly different. In the first case you have a definite quantity of your remedy immediately absorbed into the blood and circulating with it ; in the second, your remedy is slowly absorbed in indefinite quantity, and there is no reason that I know of why some of it should not pass out of the body in the residue of the food with which you have allowed it to be mixed !

When the initial stage is passed, and the nasal fluxion is thoroughly established with a distressing feeling of oppression and stuffiness about the nasal passages and frontal sinuses, I have found the following diaphoretic draught, containing opium, to be of the greatest use. I have taken it myself and given it to others for many years.

℞ Liquor. Opii Sedat. ℥ xv.
Vini Ipecac. ℥ v.
Sp. Ætheris Nitrosi ʒ j.
Liq. Ammoniæ Acet. ʒ iij.
Aquæ Camphoræ ad ʒ i ss.

To be taken at bedtime.

If the patient is able to keep to the house, and better still, to one moderately warm room for a day or two, a single dose of this kind will not infrequently remove all the catarrhal symptoms permanently as well as immediately. But although it will surely give immediate relief, yet, if the patient exposes himself to changes of temperature the next morning the catarrhal condition will frequently return.

Opium given in this form is not attended by the unpleasant effects generally found to follow its administration in the crude, solid form, such as headache, nausea, loss of appetite, &c.

Some feverishness and slight rise of temperature frequently accompany these attacks, and in these, and indeed in all cases of the kind we are considering, we shall do wisely to give quinine in doses of one to two grains, three or four times a day. It is a valuable adjunct to the opium treatment.

I am accustomed to give it in effervescence in the following form, which seems agreeable and refreshing to patients :—

℞ Potassæ Bicarb. gr. cxx.
Ammoniæ Carb. gr. xxxii.
Syrupi Aurantii ʒ iv.
Aquæ ad ʒ viii.

M. ft. mist.

℞ Quiniæ Sulph. gr. ix.
Acid Citrici gr. cxx.

In Pulv. vi.

One of the powders, dissolved in water, and mixed with a sixth part of the mixture, to be taken three or four times a day.

In children and young people, when an attack of coryza is attended with decided feverishness, and particularly if the throat is involved, and its mucous membrane is found red and swollen, great benefit will follow the administration of a few doses of aconite. Indeed, aconite is extremely valuable in all the ephemeral and symptomatic fevers of children and young people.

I am in the habit of using Schieffelin's pilules of Duquesnil's aconitine $\frac{1}{480}$ gr. in each. I give one of these every two hours for three doses, and stop. Or you may give from one to three minims of the tincture (according to the age of the patient) every hour for three or four doses, and stop. My own experience of aconite teaches me that it is a drug which either produces an immediately beneficial effect, or is of no value. It is also a drug which is of much value in the initial stage of many febrile maladies, but of little or no use in advanced stages.

I should advise you, with regard to the internal use of aconite, to adopt this rule : give it only in a few doses at a time, and in the initial stages of disease ; never increase this dose largely, with the hope of obtaining better results from a large dose than you have been able to get with a small one.

It is of more apparent benefit in throat catarrhs, than in nasal or laryngeal catarrhs. I should rely, in the treatment of acute coryza, rather on opium and quinine ; but in children, and in persons who cannot take opium or quinine, you may give aconite, in the way I have stated, with advantage.

Camphor is a popular remedy for coryza ; a few drops of the spirit of camphor, dropped on sugar, or taken in water, every half hour, will in certain persons arrest a cold in the head, if taken in the initial stage ; but it is useless when this stage is passed, and not to be compared in efficacy with opium or morphia, given in the manner I have enjoined. Several cases are on record of poisoning by so-called homœopathic tincture of camphor, taken, in repeated doses, for this purpose.

Then there is what is called the *dry* cure, which was introduced by Dr. C. J. B. Williams. It consists in stopping the supplies of all liquids ; and so, by not adding any water to the blood, while the system withdraws from the blood the fluid required for the natural secretions, the quantity of fluid in the blood vessels is diminished and the local hyperæmia thereby lessened. The catarrh ceases because the supply of fluid to the blood is cut off ! The amount of fluid permitted was a tablespoonful of milk or tea with the morning and evening meals, and a wine-glassful of water at bedtime. But this has never been a popular method—the remedy appearing to many persons worse than the disease.

(3) Lastly, we have to consider the action of *Remedies applied Locally.*

It is rarely necessary to apply any local treatment to acute nasal catarrhs. Such treatment is more useful in the chronic forms of catarrh.

A common and popular method of attempting to cut short an attack of coryza is to inhale the vapours given off by a mixture of ammonia, carbolic acid, and rectified spirit. This mixture is dropped upon some absorbent substance introduced into a bottle and the vapour given off is inhaled by the nostrils. When there is much distress from swelling and dryness of the nasal mucous membrane, relief may be obtained by the inhalation of moist soothing vapours ; the vapours of hot water, or of infusion of camomile, or of elder flowers, or of the decoction of poppy heads. These vapours may be inhaled from the orifice of a narrow-mouthed jug, which together with the mouth and nose of the patient are covered with a towel, or they may be con-

ducted directly to the nostrils by an india-rubber tube connected with the steam-generating apparatus.

When the secretion is profuse and the nostrils feel blocked up, benefit is sometimes obtained by the application of a warm spray of a weak solution of common salt or carbonate of soda (2 to 6 grains to the ounce), or Ems Water, for a quarter of a hour at a time, four or five times a day.

Some have strongly recommended the snuffing up of a powder composed of bismuth, tragacanth powder and morphine, in the early stage of nasal catarrh. But many persons object strongly to the introduction of a sticky powder into the nostrils.

You will often find during or after an attack of acute nasal catarrh, that the catarrhal condition will extend into the pharynx and spread not unfrequently to the mucous membrane of the upper part of the larynx. The patient will then complain of an uncomfortable feeling in the throat, especially in swallowing his saliva, and he will often also be tormented by a troublesome tickling cough. This cough is generally aggravated during and after meals, and is particularly annoying on lying down in bed at night.

On looking into the throat you will usually find the soft palate and uvula somewhat relaxed, a spongy aspect about the tonsils, and the mucous membrane of the pharynx redder than usual and covered with whitish mucus in patches or streaks.

The reason why, in some of these cases, the patient only complains of cough when he assumes the horizontal position is because then the larynx falls back against the posterior wall of the pharynx, and the drainage of the catarrhal secretion from the pharynx, instead of flowing off by the œsophagus, trickles into the aperture of the larynx, and so excites cough. Sometimes the trailing of an elongated uvula has the same effect

When the cough is brought on by eating and drinking, the catarrhal state has probably extended to the upper part of the larynx, and the increased supply of fluid and nutritive material to the blood is attended by increased fulness of the vessels, and increased secretion from the catarrhal surface, thus giving rise to cough for its expulsion. Local treatment is of especial value in relieving these conditions.

The mucous membrane should be cleansed of the more or less tenacious mucus adherent to it by alkaline sprays or gargles. Warm Ems and Bourboule Water are both good for this purpose ; or a warm spray of a solution of carbonate of soda, 5 to 10 grains to the oz., to which a few grains of common salt and a few drops of glycerine are added, may be advantageously used.

These solutions may be applied by means of a hand spray, or a Seigle's steam spray producer.

The mucous membrane having been thus cleansed by these alkaline sprays, astringent applications will now take much greater effect on the dilated vessels, and gargles and sprays of solutions of alum, or tannin, or perchloride of iron will be found useful. Or stronger solutions may be applied directly to the pharynx by means of brushes. The glycerine of tannin of the British Pharmacopœia is a good application in some cases.

In some instances gargles containing both alkaline and astringent ingredients prove very serviceable, and many patients prefer them to the trouble of spraying. A good gargle for this purpose consists of 1 drachm of chlorate of potash, 2 drachms of aromatic spirits of ammonia, and half-an-ounce of tincture of catechu to 8 ozs. of water. Another good form consists of half-an-ounce of glycerine of borax, 1 drachm of chlorate of potash, half-an-ounce of tincture of Rhatany, and 8 ozs. of water.

If there is much laryngeal irritation an occasional lozenge of morphine and ipecacuanha will usually allay it. But in troublesome cases, you will find one of the most reliable resources for getting rid of the catarrh and with it the teazing cough, is to brush the mucous membrane of the pharynx, the posterior surface of the soft palate and the upper part of the larynx, so far as it is readily accessible, with a solution of nitrate of silver, 10 grains to the ounce. I have found this expedient give speedy relief when other measures have failed.

Gargling the throat with ice-water before sitting down to a meal, or before going to bed, will often, in slight cases, prevent the attacks of cough of which I have spoken. In similar instances, a gargle of port wine after a meal is both pleasant and serviceable.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Epidemiological Society of London.

(Continued from page 627.)

Diphtheria and Croup.

UNDER the head of *Aphthæ*, I shall allude to the fact that Anglo-Indian children and adults returned from the East often suffer severely from exudative inflammation of the soft palate and fauces, which, at first sight, suggests the idea of diphtheria, and which has, I believe, been mistaken for that disease, much to the detriment of weak and nervous patients. I have seen a good deal of thrush in patients, mostly aged, dying from exhausting diseases ; the alliance of this condition to diphtheria appears to be very close.

Nothing but the discovery of exudation in the air passages of one whose symptoms I had observed to be those usually ascribed to true croup—not those of ordinary diphtheria—would convince me that I had seen a case of deadly croup. Never having seen such a case, I remain in a state of agnosticism on this important point ; but, as I have already said, with a strong bias towards the opinion of those observers who regard "membranous croup" as "diphtheria of the air passages."

Mackinnon describes *Hooping Cough* as being epidemic in India (p. 128). In his experience, it was not extremely prevalent or aggravated in type in the plains of the North Western Provinces. But, when he wrote, it was very severe at the hill stations, "where," he says, "many deaths take place from it yearly among the European children." This was written just as I went to India. I did not hear of the occurrence of such deaths in my time. He adds, "It prevails as an epidemic all over the plains of the Ganges, usually in a very mild form, and most commonly showing itself at the same time of the year with the exanthemata so allied to it in many particulars."

In a later communication[7] Mackinnon stated his opinion that the exanthemata and hooping cough are all known most commonly to show themselves at the change of season which ushers in the hot weather. He has sometimes seen the disease "so mild as to render it difficult to distinguish it from common cough, although the manner in which the cough attacks, in fits more or less violent, and the specific hoop ought to be enough to guide us." Noting the fact that an attack usually renders the individual exempt from future visitation, he observes, that he has known children, who have had well-marked hooping cough in India, have the disease again severely in Europe. He again notices that, at some of the Indian hill stations, the disease is

[7] *Ind. An. Med. Sc.*, No. 3, for 1855, p. 178.

severe and even fatal; which, he adds, seems to be another proof that, in the plains, it owes its generally mild character to the high range of temperature.

In a return, showing that the average strength for three years of European soldiers' children was 2,291, he found that there were only 23 cases of pertussis, being about eight per annum out of that strength. There was only one death.

In his invaluable statistical tables, so frequently cited in these chapters, my friend, Surgeon-General Hugh Macpherson, shows that, during the four years ending 1853–54, there occurred, in the European regimental hospitals in the Bengal Presidency, six cases of hooping cough among soldiers, but no deaths. No cases of officers or women; 29 cases among children, or $\frac{3}{10}$ per cent. of strength, and two deaths or $6\frac{9}{10}$ per cent. of treated. Dr. T. Farquhar reported that, at Mussoorie in 1862, there were 45 cases of hooping cough and one death from pneumonia.

Among the 7,596 *children* of European soldiers in India in 1880, there were 104 admissions for hooping cough and three deaths. In 1881, there were admitted in Bengal 27 children, in Madras 12, and in Bombay 28, of whom two died. In 1882, there were 22 admissions and one death in all India. In the three years only one of the large body of native prisoners was attacked—in 1881; in 1880, two Bengal Sepoys had hooping cough; and in 1881, a Bombay man was admitted. No other cases occurred in our native army in the three years.

Hooping cough prevailed from time to time in Calcutta. Few of the cases which I had were severe, but, when tracheotomy was recommended in pertussis, I opened, ineffectually, the trachea of an East Indian infant at the moment when it ceased to breathe. A man in my ward was in considerable danger from pneumonic complication. I never saw phthisis set up by pertussis in India, and I did not hear of European children sent home to recover from its effects. Morehead says, "In Dr. Coles's Report on Measles in the Byculla Schools, allusion is made to the presence of three cases of hooping cough at the same time. I do not find any account of the epidemic prevalence of this disease in these schools: but my impression is that it has occurred, from time to time, during the last twenty years. In a note to the case of a child who died, as he considered, after recovery from hooping cough, Webb remarked, "This is the only fatal case which I have met with in hooping cough in India. The disease has twice gone through the children of the Government Orphan School during the last four years, and once through La Martinière Institution."

Parotides.—Mumps are occasionally epidemic in India, the disease usually assuming the ordinary mild European type, and being unattended with severe fever or grave complications. But, on one occasion, I witnessed an unusual outbreak of this malady. There was, at Howrah, a single row of unhealthily situated detached houses, leading down to Tel Khal Ke Ghat, principally inhabited by respectable Europeans. In front, separated only by the highway, ran an open, ill-dug earthen ditch, which was intended to carry the excreta of the large native jail to the river Hooghly, but was practically an elongated reservoir of stagnant filth. Several European children in this row were attacked with mumps. The disease appeared to be endemic; I did not see or hear of any cases elsewhere. In most of the cases the attack was mild and the children did well; but, in one of the houses, two fine little European boys became the subjects of acute membranous laryngitis, without the constitutional symptoms of diphtheria, when the parotid swelling was subsiding. There was no exudation about the fauces, but vomiting detached shreds from the air passage. The younger boy died suddenly while in the act of coughing. I found that the exudation tube, having become detached below, had been forced upwards and rolled together, and had completely filled and blocked the larynx. Had I been present when the accident occurred, laryngtomy would probably have saved him. The elder brother did well. The coincidence of diphtheria with mumps has been observed elsewhere. Morehead says,[8] that cynanche parotidæa attacked the Byculla girls' school, Bombay, in March, 1837. Seventy-four girls were affected, not a single boy. Mr. Carter reported that it broke out among the boys in October and November, 1851. Seventy-five boys were affected, but only two girls.

The returns show that, in 1881, there were 23 admissions of European soldiers' children, for mumps, in all India. During that year the admissions of Sepoys, under this heading were 1,180, in a strength of 114,612. Of the 100,844 prisoners, 785 had mumps. It is noteworthy that in this year Sepoys were attacked in all the Presidencies, so also was the jail population, who are much isolated. There were some cases among the prisoners in British Burmah, and in the Andaman Islands. It is not shown whether the European soldiers were attacked; their wives were not. Cases occurred among their children in each of the Presidencies. In 1882, 2 soldiers' wives and 14 of their children were admitted, and 901 Sepoys and 769 prisoners had mumps, the disease occurring throughout British India and Burmah, but not in the Andamans.

Influenza.—Dr. John Adam placed on record[9] an account of what he termed an "epidemic bronchitic fever" of infants and young children, which prevailed in Calcutta during the rains, or months of June, July, and August, 1828. This was preceded by a perhaps less general epidemic in 1824. In Dr. Adam's experience, not one child under four years of age out of a hundred escaped an attack. The victims were, for the most part, fine infants at the breast. Death did not occur in any child above two years old. The symptoms were those of capillary bronchitis, ushered in by a febrile paroxysm. In convalescence, there was a "degree of weakness which was extremely protracted and difficult to remove." This epidemic was not confined to the city and suburbs of Calcutta, but extended to many stations in Lower Bengal. It prevailed at Chinsurah, Burdwan and Bhauleah, and even as far northward as Maldah. In Calcutta native children do not appear to have been attacked; but at Burdwan they suffered considerably. Here the adult natives had fever similar to that of the children, with the difference that "it was accompanied by a troublesome ophthalmia."

This epidemic appears to have about doubled the average death-rate of European infants in Calcutta. Three years later, in 1831, a remarkable outbreak of influenza occurred in Penang and Java. It was described by Dr. T. M. Ward[10] as "the epidemic catarrh which prevailed at Penang in July and August, 1831." Few of the inhabitants escaped a more or less severe attack. It affected at once whole families, attacking both sexes, young and old, of all races indiscriminately. It destroyed many old and infirm natives. There was fever with bronchitis. "The depression of strength and spirits was considerable during the continuance of the febrile symptoms;" and, in convalescence, "the patients were weak and languid."

Again, three years later, in January, February, March, and April, 1834, it was reported[11] that "catarrh prevailed in Calcutta on so general a scale that it might be termed epidemic." "It attacked equally children and adults." "It ran its course through families with

*

great severity." "In some cases the affection of the head and larynx was very severe," and in others pneumonia occurred; but there do not appear to have been any fatal cases. This was distinctly recognised as influenza. Two years and seven months later still, occurred the great outbreak of influenza in England and France. Although I was a young student, I watched the progress and effects of the terrible influenza epidemic with which London was visited at the end of 1836 and in 1837, very fully and carefully, at Guy's Hospital. The main characteristics of this outbreak were debility and capillary bronchitis. Multitudes of aged people died; and, for several years afterwards, phthisical patients traced back their loss of health to the influenza of 1837. Webb, writing in 1848, speaks of the "severe influenza of Bengal;" but Mackinnon[12] says, with less than his usual cogency of argument, that influenza had not been described by Indian authors, and that the disease was unknown in India. Assuredly there was not any great outbreak of influenza in that country in Mackinnon's or in my own time. I never saw anything of the kind there graver than a prevalent catarrh, neither has the United Kingdom been ravaged by this disease since 1837. Still I fully believe that, wherever catarrh or bronchitis runs through a town or a household, as they frequently do, both in India and at home, the malady is influenza, epidemic or endemic.

I am confident that any epidemiologist who will carefully review, in the originals, the narratives which I have cited, will feel convinced that an influenza wave extended from India to England between the years 1824 and 1837.

I saw a fatal case of *Glanders* at Guy's, and offered to examine the body after death, but was not allowed to do so. I never saw this disease, or *Farcy*, in the human subject in India, although these maladies frequently attack studs in that country. A marked case of glanders, occurring in a native syce driver belonging to the 5th Battalion of Artillery, who was found to have had something to do with the veterinary department, and ten weeks previously had assisted in a *post-mortem* examination of a horse which died with a discharge from the nostrils, was described[13] in 1855 by Mr. Halls.

(*To be continued.*)

AN EXAMINATION OF THE THEORY OF AËRIAL DISSEMINATION OF SMALL-POX INFECTION.

By MONTAGUE D. MAKUNA,
Late Medical Superintendent of Fulham Small-pox Hospital.

(Continued from page 729).

The Year 1879.

We learn from the Report of the Registrar-General that during the year there were 458 deaths from small-pox in London, of which 10 were in Kensington, 5 in Chelsea, and 118 in Fulham, including 111 in Fulham Small-pox Hospital. The Metropolitan Asylums Board Hospitals admitted 1,685 patients, including 144 from Fulham, 113 from Kensington, and 105 from Chelsea. The Highgate Hospital had admitted 7 from Chelsea, 5 from Kensington, and 1 from Fulham. The cases reported to the Medical Officers of Health, were 166 in Fulham Union, of which 133 were in Fulham parish, 139 in Kensington, and 121 in Chelsea, giving 426 known cases in the three districts. By calculating 15 per cent as mortality among private cases, we estimate the total incidence for the three districts, 521 cases, of which Mr. Power accounts for 382 cases. The proportion of cases unaccounted for this year is not so large as in the previous years, on account of the better organisation for the removal of cases to the Metropolitan Hospitals and for effectually dealing with the concealment of cases. I utilised my experience of the previous two years, and conducted my investigations into the history of the cases with more precision and better results. I discovered that small laundries in Chelsea were a fruitful source of the disease, as infected clothing of concealed and private cases was washed without any precaution. The washing of many families in the S. A. was done there. A severe outbreak occurred in Land's End, Fulham, ½ and ¾ mile R., principally in the families of workmen of the Imperial Gas Factory, in the months of April and May. The workmen also lived on the other side of the water, in Battersea and in Chelsea. There were several cases of small-pox in the families at Battersea, and some of them were sent to Fulham Hospital in February and March, which clearly demonstrates that the disease was imported in Sand's End, Fulham, as will be seen from the detailed history to follow. In my Annual Report I pointed out to the Managing Committee of the Fulham Hospital several imperfections, and the insanitary condition of the buildings, and recommended improvements and proper accommodation for the members of the staff—defects existing with the opening of the hospital, which were left unnoticed as in the past years.

January.—Fulham Hospital admitted 31 acute cases, viz., 6 from Fulham, 3 from Kensington, 3 from Chelsea, 8 from St. George's, 4 from Wandsworth, 3 from Paddington, 1 from Strand, 1 from St. Giles's, and 2 from St. Saviour's; 25 convalescents were transferred from other hospitals. The cases known to Health Officers were 7 in Fulham, 4 in Chelsea, and in Kensington, during the four weeks ending 5th February, 7 cases. The weekly number of cases under treatment in Fulham Hospital was 17, 18, 19, 50 and 44.

Fulham Cases.—All admitted to Fulham Hospital. (1) One from 11, Farm Lane, C. C., on the 21st. Infected street. (2) One from 16, Hildyard Road, C. C., on the 31st. Infected street. (3) One from 6, Caroline Place, ¾ mile R., on the 19th. (4) One from 27, Rectory Place, 1 mile R., on the 24th. (5) One from 21, Coomer Road, 1 mile R., on the 31st. (6) One from Hammersmith Baths, O. S. A.

Kensington Cases.—(1) A waiter treated at home in 109, Ifield Road, C. C. Dr. Dudfield states he was engaged in obtaining signatures to a memorial to Sir C. Dilke, to bring in a Bill to do away with the Fulham Hospital. He probably took the disease while about his singular mission. He did his best to conceal his case. (2 to 5) Four cases in Richmond Road, ½ mile R. A domestic from 90, on the 6th, to Fulham Hospital. Two fatal cases of a recently confined mother and the infant at 70, revealed by the death certificate of the mother. A fishmonger in 104, who also tried to conceal his case from the lodgers, was treated at home. (6) A domestic from 29, Hollywood Road, ½ mile R., to Fulham Hospital, on the 1st. (7) A cook, from 29, Coleherne Road, ½ mile R., to Fulham Hospital, on the 10th. (8) A barmaid died at home on the 11th, at 4, Pelham Street, O. S. A.

Chelsea Cases were—One from 64, Church Street, 1 mile R., to Fulham. (9 and 10) A coachman and his wife, private concealed cases in Sumner Mews, O. S. A.

[12] "On the Epidemics of Bengal and the North West Provinces," *Ind. An. Med. Sc.*, No. 5, p. 128.
[13] *Ind. An.*, No. 4., p. 707.

Chelsea Cases.—One from 64, Church Street, 1 mile R., to Fulham Hospital on the 9th; and one each from Markham Street and Keppel Street, O. S. A.

February.—Fulham Hospital admitted 107 acute cases, viz., 15 from Fulham, 8 from Kensington, 23 from Chelsea, 32 from St. Saviour's, 9 from Wandsworth, 5 from St. George's, 2 from Westminster, 10 from Lambeth, 2 from Paddington, and 1 from Brentford. Highgate Hospital admitted 3 from Chelsea. The Health Officers report 17 cases in Fulham, 27 in Chelsea, and in Kensington, during four weeks ending 5th March, 11 cases. The weekly number of cases under treatment in Fulham Hospital was 62, 79, 90 and 93. Of the Wandsworth cases 5 were from Battersea, S. A. One was a brother of a workman in the Imperial Gas Factory, who was admitted last month; a lighterman from Bridge Road, two labourers and a laundress.

Fulham Cases.—Admitted to Fulham Hospital. (1 and 2). A girl from 6, and a smith from 38, Farm Lane, C. C., on the 20th. Infected street. (3) A married female from 9, Jordan Place, ½ mile R., on the 5th. (4 and 5) Two boys from 6, Stanley Road, ½ mile R., on the 7th and 9th. An infected street. (6) A girl from 3, Percy Place, ½ mile R., on the 13th. (7) A labourer from 3, Schofield Terrace, ½ mile R., on the 15th. (8 to 10) A mother and a baby on the 23rd, and a child on the 27th, from 13, Little Ebenezer Place, ¾ mile R. (11 and 12) A girl from 12, and a girl from 19, Hilmer Street, ¾ mile R., on the 1st and 27th. An infected street. (13) A labourer from 18, Serf's Terrace, ¾ mile R., on the 4th. (14) A boy from 10, Broxholm Road, ¾ mile R., on the 19th. Infected house. (15) A girl from 21, Coomer Road, 1 mile R., on the 12th. Infected house.

Kensington Cases.—Admitted to Fulham Hospital. (1) A child from 3, Redcliffe Street, ½ mile R., on the 28th. (2) A labourer from 8, Child's Place, ¾ mile R., on the 27th. Infected street. (3) A boy from Industrial School, 1 mile R., on the 23rd. (4 to 8) Five from O. S. A., viz., one each from Lonsdale Road, Moreton Gardens, Goldborne Road, Cornwall Road, and William Street.

Chelsea Cases.—(1) A labourer from 6, Seaton Street, ¾ mile R., on the 8th. (2 to 26). Twenty-five from O. S. A., viz., 3 from Godfrey Street, 3 from Cole Street, 2 each from Norman Street, Markham Terrace, Sloane Street, Brewer Street, and Jubilee Place; and one each from Rawling's Street, Smith Street, Albert Cottages, Little College Street, Francis Street, Exeter Place, College Place, and Marlborough Road. This outbreak was caused by a fatal concealed case in 46, Godfrey Street, O. S. A., and the case of the landlord of the public-house "Blenheim." Eighteen of the above cases were traced to this source. Many infected families migrated from the neighbourhood, after the outbreak, into various localities. The unequal distribution of cases in the several areas of Fulham, Kensington, and Chelsea, and at widely different dates, occurring in infected streets, points to outbreaks due to local causes—a feature I have repeatedly pointed out in the history of 1877, and 1878. It will also be made evident in the history of the years 1879 and 1880.

March.—Fulham Hospital admitted 112 acute cases, viz., 24 from Fulham, 22 from Kensington, 17 from Chelsea, 21 from St. Saviour's, 7 from Lambeth, 7 from Wandsworth, 3 from Westminster, 1 from St. Giles's, 2 from Brentford, and 8 from St. George's. Highgate Hospital admitted one from Kensington. The Health Officers reported 19 cases in Chelsea, 24 in Fulham, and in Kensington, for four weeks ending 2nd April, 28 cases. The weekly number of cases under treatment in Fulham Hospital was 101, 98, 106 and 99. Of the Wandsworth cases five occurred in Battersea, on the outskirts of S. A., and one in the family of a workman in the Imperial Gas Factory, Sand's End, Fulham.

Fulham Cases.—(1) A married female from 9, Rickett Street, C. C., on the 7th. Some members of the hospital staff lived here. (2) A joiner from 16, Sherbrook Road, ½ mile R., on the 2nd. (3) A schoolmaster from 37, Cornwall Street, ½ mile R., on the 3rd. (4) A married woman from 4, Whitechurch Cottages, ½ mile R., on the 4th. (5 and 6) A carpenter and his wife from 20, Bective Road, ½ mile R., on the 9th and 24th. (7) A labourer from 27, Bullow Road, ½ mile R., on the 9th. (8) A labourer from 3, Carpenter's Row, ½ mile R., on the 13th. He was at work in the Imperial Gas Factory till the fourth day of eruption. (9) A workman in the same Gas Factory from 21, Cornwall Street, ½ mile R., on the 14th. He was at work till the seventh day of eruption. (10) A boy from "Stamford Arms," ½ mile R., on the 27th. (11 and 12) A warehouse boy from 8, and a carman from 55, Victoria Road, ½ mile R., on the 23rd and 29th. (13 and 14) Two from 13, Little Ebenezer Place, ¾ mile R., on the 3rd and 6th. An infected house. (15) A messenger from 10, Broxholm Road, ¾ mile R., on the 4th. An infected house. (16) A child from 8, George's Square, ¾ mile R., on the 7th. The case was treated at Kensington Dispensary. (17) A plasterer from 7, Crown Road, ¾ mile R., on the 19th. (18) A domestic from 7, Parson's Green, ¾ mile R., on the 20th. An infected house. (19 to 24) Six from O. S. A., viz., 1 each from Devonport Road, George Street, Flora Villas, Rose and Crown Lane, Dalling Road, and Broadway.

Kensington Cases.—(1 to 4) Four from Ifield Road, C. C.; a domestic from 126, in a dying condition on the 2nd; a married female from 158 on the 19th, believed to have been infected by previous lodgers; the family migrated to 95; a barmaid from 59 on the 15th. She took it from No. 16 Fulham case for this month; 1 from 22 on the 21st. (5 and 6) Two domestics from 113 and 54, Finborough Road, C. C., on the 8th and 23rd. (7 and 8) Two from Redcliffe Gardens, ½ mile R.; a domestic from 100, on the 11th, a domestic from 76, on the 27th, by visiting her aunt at 87, Adrian Terrace. (9) A domestic from 24, Redcliffe Mews, ½ mile R. An infected house. (10) A domestic from 13, Tregunter Road, ½ mile R., by visiting her relations in South Parade, Chelsea. (11) A shoemaker from 40, Seymour Place, ½ mile R., on the 29th. (12) A stableman from 21, Kranmer Mews, ½ mile R., on the 3rd. (13) A mason from 7, Shaftesbury Terrace, ¾ mile R., on the 5th. (14 to 23) Ten from O. S. A., viz., 5 from 329, Portobello Road (a baker's shop and a dairy), where there had been a fatal concealed case without isolation or any precaution from 24th February to 8th March, and the death certificate was returned as "Congestion of the Lungs." One each from Warwick Terrace, Norland Square (from a concealed fatal case), Queen's Road (from the one preceding), Yeoman's Row (infected street), and Royal Crescent.

Chelsea Cases.—(1) One from 46, Slaidburn Street, ¾ mile R., on the 21st. Infected house. (2) One from 14, Park Walk, ¾ mile R., on the 28th. (3) A domestic from 7, Hans Place, 1 mile R., on the 7th. (4 and 5) An ironer from 478, King's Road, 1 mile R., on the 5th, and a domestic from 303, on the 29th. (6 to 17) Twelve from O. S. A., viz., 2 from Manor Buildings (infected), 1 each from Ovington Street, Cheyne Walk, Robert Street, Langston Street, Onslow Dwellings, Pimlico Road, White Hart Court, Charlotte Street, Portobello Terrace and George Street; 6 of these cases were traced to the fatal case at 43, Godfrey Street, whose history is given in last month.

April.—Fulham Hospital admitted 106 acute cases, viz., 36 from Fulham, 24 from Kensington, 17 from Chelsea, 8 from St. Saviour's, 5 from Lambeth, 4 from St. George's, 6 from Wandsworth (of which 5 were from Battersea), 2 from Paddington, 2 from West-

minster, 1 from St. Giles's, and 1 from Brentford. The Health Officers reported 41 in Fulham, 18 in Chelsea, and 27 in Kensington. The Highgate Hospital admitted 1 from Kensington and 1 from Chelsea. The weekly number of cases under treatment at the Fulham Hospital was 84, 82, 83, and 94. The Fulham Hospital is between the Lillie Bridge and Stamford Bridge Running Grounds, and on the 4th, 11th, 14th, and 15th of April, thousands of people from all parts had congregated there to witness the sports. Dr. Dudfield addressed a letter to the medical profession through the medical journals, requesting information regarding any patient with small-pox that might occur in their practice, who might have visited those grounds, to put the question of aërial dissemination of small-pox infection to a practical test, when the hospital was in full working and the admissions were large. He received no reply to it. My enquiries amongst subsequent admissions did not give any better results, nor, I believe, did others, even the opponents of the hospital, get any information. Had there been a charging of atmosphere with infection, as Mr. Power would have us believe, we might have received some corroboration of his opinion.

Fulham Cases.—(1) A boy from 6, Bullow Road, ½ mile R., on the 26th. (2) A smith from 14, Rock Avenue, ½ mile R., on the 25th. (3) A joiner from 30, Cornwall Street, ½ mile R., on the 25th. (4) A mason from 7, Cambridge Terrace, ½ mile R., on the 5th. (5) A labourer from 40, Clyde Road, ½ mile R., on the 28th. (6 to 16) Eleven from Tyrrell's Cottages, ¾ mile R.; 8 from 4, a family of Hook's, a workman in the Imperial Gas Factory, where men with eruptions on them were at work; and, as is shown above, first outbreaks occurred among them in Battersea and Chelsea. Three from No. 5, next door, another workman's family. First on the 18th and the last on the 23rd. (17) Another workman from 11, Rear Gate, ¾ mile R., on the 23rd, a brother of the Hooks. (18 and 19) Two children of another workman from 25, Imperial Cottages, ¾ mile R., on the 24th and 26th. Traced to Hook's. (20) A woman from 19, Stanley Road, ½ mile R., on the 28th. She had removed from 5, Tyrrell's Cottages, on the 22nd. (21) A barman from "Adelaide Arms," ¾ mile R., on the 28th. Traced to Hook's. (22) One from Rose Cottage, ¾ mile R., on the 29th. Traced to Hook's. (23 and 24) Two from 1, Sand's End Lane, ¾ mile R., on the 22nd and 29th. Traced to Hook's. Thus the preceding 19 cases were traced to one source, and caused by the concealment of a case at home, which was treated by a medical man for measles till too late. The particulars of this outbreak cast a serious reflection on the medical men who have cared more for themselves than for public health and good of others. Space forbids me from giving the details. (25 to 29) Five from another workman's family at 7, Wheatsheaf Alley, ¾ mile R., and 1 on the 25th, and 4 on the 30th. Caused by a concealed case. (30 and 31) Two workmen from Peterboro' Lane, ¾ mile R., on the 14th and 29th. (32) A boy from 3, Providence Row, ¾ mile R., on the 6th. (33 to 36) Four from O. S. A., viz., 1 each from Latimer Road, Carlton Terrace, Fulham Workhouse, and Rutland Terrace. The last one was a son of a railway inspector. He first lived in Notting Hill, and left a child ill with small-pox in charge of a woman, and migrated to Walham Green, ½ mile R., where his wife died of small-pox. He then shifted to the above address. After the removal of his son to hospital he took up his lodgings near Earl's Court Station. He was at work on the station all the while! He left all the houses infected.

Kensington Cases.—(1 to 6) Six from Ifield Road, C. C. An infected street. A domestic from 51, Ifield-road, on the 20th, by visiting at 68, where there were 3 concealed cases. A mason from 83, on the 17th. A blacksmith from 26, on the 23rd. A girl in 48, reported on the 12th. A painter in 36, reported on the 19th. A workman in 126, on the 19th. Most of these houses inter-communicate, and the cases might have come in contact with concealed ones. (7 and 8) A domestic from 49, Finborough Road, C. C., on the 6th. Another from 127, walked down to the hospital on the 1st. She was in the service of a member of the Managing Committee of Fulham Hospital. (9) A waistcoat maker from 8, South Street, C. C., on the 28th. She came to live here on the 26th, from Notting Hill. (10) A domestic from 57, Redcliffe Square, ½ mile R., on the 13th, by visiting her sisters in Shaftesbury Road, where there were cases of small-pox. (11) A domestic from 47, Redcliffe Square, ½ mile R., on the 17th. (12) One from 3, Earl's Court Square Mews, ½ mile R., on the 18th. (13) A domestic from 45, Tregunter Road, ½ mile R., on the 18th. (14 and 15) A domestic from 26 and another from 29, Coleherne Road, ½ mile R., on the 21st and 23rd. (16) A painter from 26, Seymour Place, ½ mile R., on the 21st, by visiting his friends in 68, Ifield Road. (17) An errand boy from 14, Ashley Cottages, ¾ mile R., on the 3rd. (18) A painter from 56, Earl's Court Road, 1 mile R., on the 21st, from a private case. (19) A domestic from 135, Gloucester Road, 1 mile R., on the 15th. (20 to 28). Nine from O. S. A., viz., 3 from Dartmoor Street, and 1 each from Warwick Terrace (infected house), Yeoman's Row (infected house), Archer Mews, South Place, Brompton Consumption Hospital (infected at home in Walham Green), and Queen's Gate (infected at home in Charlotte Street Chelsea.)

Chelsea Cases.—(1) A domestic from 231, Fulham Road, ¾ mile R., on the 14th. (2) A domestic from 33, Little Camera Street, ¾ mile R., on the 16th. (3) One from 4, Limerston Street, ¾ mile R., to Highgate Hospital, on the 18th. (4) A baker from 69, Arthur Street, 1 mile R., on the 15th. Caught it from one of his customers. (5 to 17) Thirteen from O. S. A., viz., 6 from 1, Charlotte Street (a case from the same house in March last), and 1 each from Schofield Street, Redburn Street, Anderson Street, St. Anne's Convent (infected house), Wickham Place, Lawrence Street, and 2 from Portobello Terrace.

May.—Fulham Hospital admitted 92 acute cases, viz., 25 from Fulham, 16 from Kensington, 9 from Chelsea, 9 from Wandsworth, 4 from Putney, and 5 from Battersea, 6 from Marylebone, 4 from Paddington, 3 from St. Pancras, 3 from Lambeth, 8 from St. Saviour's, 8 from St. George's, and 1 from St. Giles'. Highgate Hospital admitted 1 each from Fulham, Kensington, and Chelsea. The Health Officers reported 33 cases in Fulham, 10 in Chelsea, and 10 in Kensington during the four weeks ending 28th May. The weekly number of cases under treatment at Fulham was 95, 102, 105, 93, and 92. There were 2 convalescents transferred from Hampstead Hospital. A newly appointed Manager of the Fulham Hospital Committee walked the hospital wards and took the disease. He was treated for skin affection by another manager, a medical man, and he went about town and country as usual. His wife took it from him. Her medical attendant protested against such a procedure and gave me all the facts of the case. (See *Medical Times and Gazette*, June 17th, 1882, case 8, page 634, and case 11, page 635).

Fulham Cases.—(1) A boy from 6, Garden Row, C.C., on the 7th, from a fatal concealed case. (2 and 3) A gardener, and his wife, a laundress, from 14, Farm Lane, C. C., on the 14th and 16th. The woman nursed three cases of small-pox in 10, Harwood Road, ½ mile R., where her husband was in service, and went backwards and forwards doing her laundry work. (4) A grocer from 1, Lillie Bridge Road, C. C., on the 16th. Four

weeks previously he engaged a girl from Crown Street, convalescent from small-pox; his son took the disease from her, and was concealed at home; he took it from his son, nursing him and minding the shop as usual. (5) A boy from 6, Bullow Road, ½ mile R. An infected house. (6) A female from 4, Kempson Road, ½ mile R., on the 22nd. Her landlady's child was treated for small-pox by a chemist, attending his shop daily. (7) One from 1, Cornwall Street, ½ mile R., on the 23rd. Infected street. (8) A laundress from 27, Maxwell Road, ½ mile R., traced to Hook's. (9) A workman in the Imperial Gas Factory, from 8, Wheatsheaf Alley, ¾ mile R., on the 5th. Five cases next door last month. (10) An ironer from 21, Crown Street, ¾ mile R., on the 8th. She took it from 7, Wheatsheaf Alley. (11) A boy from 26, Pamerall Road, ¾ mile R., on the 8th. (12) A stoker from 78, May Street, ¾ mile R., on the 10th. A hospital porter lived in the house with him. (13) A tailor from 28, Anselm Road, ¾ mile R., on the 13th. (14) A child from 19, Imperial Square, ¾ mile R., on the 16th. Traced to Hook's. (15) A child from 13, Broxholm Road, ¾ mile R., on the 17th. Infected street. (16) One from 67, Estcourt Road, ¾ mile R., on the 23rd. (17 to 26) Ten cases from O. S. A., viz., 2 from Southbrook Street, and 1 from Devonshire Villas, were traced to the same source; 1 each from Acton Vale Gardens, Faroe Road, Broadmoor Terrace (by washing infected clothing), Beaumont Street (from a concealed case outside the district), White Hart Court, St. John's Terrace, and Studland Street.

Kensington Cases.—(1) A gardener, from 44, Ifield Road, C. C., on the 11th. He was living here since 24th March, and a fatal case of small-pox had occurred in the house. (2) A flower mounter from 9, Stamford Cottages, ½ mile R., on the 31st. (3) A cook from 10, Rich Terrace, ½ mile R., on the 28th, from a concealed case. (4 and 5) Two cases were treated at Kranmer Mews, ½ mile R. (6) One from Edward's Square, 1 mile R., on the 30th. (7 to 9) Three from Earl's Court Road, 1 mile R., 2 from 32, on the 12th and 26th, caused by a private case; and 1 from 56, on the 6th, traced to the same source. A case from the same house last month. (10 to 12) Three boys from Industrial School, 1 mile R., 1 on the 12th, and 2 on the 13th. A boy from the same in February. (13) A boy from 25, Merton Road, 1 mile R., on the 26th, by visiting his relations in Lambeth, who was removed to Stockwell. (14) A butler, from 25, Onslow Gardens, 1 mile R., to Highgate Hospital, on the 12th. (15) A dressmaker from Abingdon Villas, 1 mile R., on the 31st. (16 to 19) Four from O. S. A., viz., 1 each from High Street, Bonchurch Road, Portland Road, and Victoria Grove. The last was caused by the visit of a convalescent, and removed to the hospital after he had been violently delirious, and driven in a cab.

Chelsea Cases.—(1) One from 109, Lot's Road, ½ mile R., on the 31st. (2) One from 43, Slaidburn Street, ¾ mile R., on the 3rd. (3 and 4) One each from 27, and 29, Luna Street, ¾ mile R., on the 8th and 29th. (5) One from 43, Seaton Street, ¾ mile R., on the 29th. (6 to 10) Five from O. S. A., viz., 1 each from Lower George Street (infected house), Moor Street, Wood Street, First Street, and Durham Street.

June.—Fulham Hospital admitted 82 cases, viz., 17 from Fulham, 25 from Kensington, 15 from Chelsea, 5 from Marylebone, 5 from St. George's, 5 from Paddington, 5 from St. Pancras, 2 from Brentford, 2 from St. Giles's, and 1 from Hampstead. Highgate Hospital admitted 1 from Chelsea. The Health Officers reported 20 in Fulham, 20 in Chelsea, and in Kensington 27, during the four weeks ending 6th June. The weekly number of cases under treatment was 99, 90, 82, and 82.

Fulham Cases.—(1) A child, from 2, Roxby Place, C. C., on the 23rd. On my suggestion, Fulham Sanitary Authorities made a house to house inspection, and discovered the case. A woman kept here a baby farm, and several cases of small-pox spread from here. (2) A coal porter in the Gas Factory from 4, Garden Row, C. C., on the 25th. Small-pox next door. (3) A woman from 7, Stamford Street, ½ mile R., on the 10th, traced to Hook's. (4) A clerk from 59, Waterford Road, ½ mile R., on the 7th, by visiting a friend's house where there were 3 cases of small-pox. (5) A woman from 14, Waterford Road, ½ mile R., on the 3rd. (6) A carpenter from 23, Vaunston Place, ½ mile R., on the 10th. (7) A labourer, from 32, Victoria Road, ½ mile R., on the 25th. (8) A gardener from 40, Britannia Road, ½ mile R., on the 1st. (9) A carpenter from 23, Vaunston Place, ½ mile R., on the 10th. (10) A coal porter, 6, Rose Cottages, ¾ mile R., on the 4th, traced to Hook's. (11) A boy from "Maxwell Arms," ¾ mile R., on the 10th, traced to Hook's. (12) A domestic from 7, Parson's Green, ¾ mile R., on the 9th. Infected house. (13) A cook from Peterborough Villas, ¾ mile R., on the 1st. Infected house. (14) A coachman from 15, Caroline Place, ¾ mile R., on the 28th. (15) A labourer from 9, Francis Street, ¾ mile R., on the 26th. (16) A dustman from 16, Field Road, 1 mile R., on the 5th. He cleared the dustbins of the Fulham Hospital wards a fortnight previous. (17) A workman in the Gas Factory, from 11, Peterborough Road, 1 mile R., on the 8th.

Kensington Cases.—(1) A shopman from 112, Ifield Road, C. C., on the 18th. (2) A cook from 27, Redcliffe Square, ½ mile R., on the 2nd. (3) A domestic from 4, Bolton Gardens, ½ mile R., on the 6th. At the above address only a fortnight. (4) A housekeeper from 18, Bolton Gardens, ½ mile R., on the 6th. By handling infected clothing in the house of a case occurred last year. (5) A domestic from 20, Rich Terrace, ½ mile R., on the 13th. (6) A piano tuner from 7, Clow Terrace, ½ mile R., on the 13th. From a house in Finborough Road. (7) One from 39, Eardley Crescent, ½ mile R., on the 21st. (8) One from 23, Philbeach Gardens, ½ mile R., on the 26th. (9) A carpenter from 43, Kempsford Gardens, ½ mile R., on the 27th, living at the above address since the 14th. (10 and 11) A private case in 13, Child's Place, ¾ mile R., causing a case at No. 1B, removed to Fulham Hospital on the 27th. (12) A woman from 12, Devonshire Terrace, 1 mile R., on the 4th, caused by the delirious patient from Victoria Grove last month, who drove to her house. (13) A butler from 77, Onslow Gardens, 1 mile R., on the 3rd, by visiting his brother in Bridge Street, Hammersmith. (14 to 26) Thirteen from O. S. A., viz., 2 from Enson Mews and 1 each from Victoria Grove (his father admitted last month in a delirious condition), Queensbury Place, Portobello Road, South End, Fenelon Road, Stanhope Mews, Yeoman's Row, Ledbury Road (a sister of the Assistant Medical Officer, Fulham Hospital; her little brother was treated at home for chicken-pox, who is said to have contracted the disease in Victoria Docks), Cornwall Road, St. James' Street, and Edward's Place.

Chelsea Cases.—(1) A carman from 11, Lot's Road, ½ mile R., on the 19th. (2 and 3) Two from 22, Slaidburn Street, ¾ mile R., on the 7th and 21st. An infected haunt. (4) A labourer from 17, Blantyre Street, ¾ mile R., on the 2nd. (5) One from 65, Seaton Street, ¾ mile R., to Highgate Hospital, on the 10th. (6) A domestic from 235, Fulham Road, 1 mile R., on the 3rd. (7 to 16) Ten from O. S. A., viz., 3 from Arthur Street, and 1 each from Park Terrace, Falcon Terrace, Bywater Street, Upper Manor Street, Wood Street, Wellington Street, and Guthrie Street.

July.—Fulham Hospital admitted 44 acute cases, viz., 13 from Fulham, 7 from Kensington, 11 from Chelsea, 5 from St. Pancras, 4 from St. George's, 2 from Strand, 1 from St. Giles's, and 1 from Brentford.

Highgate Hospital admitted 1 from Chelsea. The Health Officers reported 13 in Fulham, 11 in Chelsea, and in Kensington 10 during the four weeks ending July 23rd. The weekly number of cases under treatment was 78, 75, 51, 46, and 45.

Fulham Cases.—(1) A domestic from 5, Seagrove Road, C. C., on the 19th. From a concealed case in Rickett Street. (2) A labourer from 34, Vaunston Place, ½ mile R., on the 2nd. (3 and 4) A coachman and his wife, from 32, Bective Road, ½ mile R., on the 7th and 20th. The Fulham Hospital carpenter lived in the house. (5 and 6) Two children of two workmen in the Gas Factory, from 1, Britannia Road, ½ mile R., on the 9th and 12th. (7) A female from 49, Waterford Road, ½ mile R., on the 16th. (8 and 9) Two children of two workmen in the Gas Factory, from 6, Broxholm Road, ¾ mile R., on the 12th and 24th. (10) A potman from "Wilton Arms," ¾ mile R., on the 3rd. (11) A labourer from 13, Crown Street, ¾ mile R., on the 7th. (12) One from 3, Orchard Street, ¾ mile R., on the 15th. (13) One from Masborough Road, O. S. A.

Kensington Cases.—(1 and 2) One each from 7 and 54, Ifield Road, C. C., on the 8th and 26th. The former resident for two months in the house. (3) A child from 13, Child's Place, ¾ mile R., on the 3rd. From a child treated at home. (4) An undertaker from 68, Abingdon Villas, 1 mile R., on the 24th. He removed a body from Fulham Hospital a fortnight previous. (5) A chemist's assistant, from 280, Fulham Road, 1 mile R., on the 4th. (6 and 7) One each from Beaufort Gardens and Brompton Road, O.S.A.

Chelsea Cases.—(1) A paper-stainer from 49, Slaidburn Street, ¾ mile R., on the 19th. An infected haunt. (2) A carpenter from 67, Limerston Street, ¾ mile R., on the 22nd. (3) One from 42, Beaufort Street, 1 mile R., on the 18th. (4 to 12) Nine from O. S. A., 2 from Manor Street, and 1 each from Arthur Street, Zealand Street, Union Place, Robert Street, Markham Square, Smith's Terrace and Margaretta Terrace.

August.—Fulham Hospital admitted 33 acute cases, viz., 5 from Fulham, 7 from Kensington, 4 from Chelsea, 12 from St. George's, 2 from Marylebone, 1 from St. Giles's, 1 from St. Pancras, and 1 from Westminster. Highgate Hospital admitted 1 from Chelsea. The Health Officers reported 5 in Fulham, 5 in Chelsea, and in Kensington 8, during four weeks ending 20th August. The weekly number of cases under treatment at Fulham Hospital was 38, 34, 37 and 33.

Fulham Cases.—(1) One from 10, Broxholm Road, ¾ mile R., on the 11th. An infected house. (2) One from 20, Estcourt Road, ¾ mile R., on the 18th. (3) A milkman from 79, Rylston Road, ¾ mile R., on the 13th. (4) One from 11, Grove Terrace, ¾ mile R., on the 14th. (5) A labourer from 6, Peterborough Road, 1 mile R., on the 29th.

Kensington Cases.—(1) One from 54, Ifield Road, C. C., on the 12th. A case from the same house last month. (2) A servant from 84, Redcliffe Gardens, ½ mile R., on the 29th. She returned from her holiday on the 27th. (3 to 7) Five from O. S. A., viz., Holmes Place, Gloucester Road, Clarendon Road, Blithfield Street, and Shaftesbury Road.

Chelsea Cases.—(1) One from Camera Cottages, ¾ mile R., on the 11th. (2 to 5) Four from O. S. A., viz., Smith's Terrace, Strewon Square, Denyer Street, and Ovington Square.

September.—Fulham Hospital admitted 12 acute cases, viz., 2 from Fulham, 4 from Kensington, 2 from Chelsea, 2 from Strand, 1 from St. George's, and 1 from St. Pancras. The Health Officers reported 2 in Fulham, 10 in Kensington, and 3 in Chelsea. The weekly number of cases under treatment in Fulham Hospital was 29, 22, 19 and 19.

Fulham Cases.—A small-pox nurse and her child from Broxholm Road, ¾ mile R., on the 23rd.

Kensington Cases.—(1) A child from 87, Ifield Road, C. C., on the 1st. (2 to 4) Two from Swinbrook Road, and 1 from Chapel Place, O. S. A.

Chelsea Cases.—Two from Henry Place, O. S. A.

October.—Fulham Hospital admitted 7 acute cases, viz., 1 from Kensington (Abingdon Road, O. S. A.), 4 from Islington, 1 from St. George's, and 1 from Lambeth. The weekly number of cases under treatment in Fulham was 14, 15, 14, 8 and 8.

November.—Fulham Hospital admitted 11 acute cases, viz., 7 from Islington, 1 from Holborn, 1 from Westminster, 1 from Wandsworth, and 1 from St. Pancras. The weekly number of cases under treatment was 8, 9, 10 and 10.

December.—Fulham Hospital admitted 21 acute cases, viz., 2 from Fulham, 3 from Chelsea, 1 from Paddington, 6 from Islington, 2 from St. Pancras, 2 from Strand, 2 from Marylebone, and 3 from Wandsworth. The Health Officers reported 2 in Fulham, and 4 in Chelsea. The weekly number of cases under treatment was 8, 12, 18 and 19. Highgate Hospital admitted 1 from Kensington.

Fulham Cases.—(1) A labourer from 5, Moorpark Terrace, ½ mile R., on the 25th. (2) A railway guard from 4, Estcourt Road, ¾ mile R., on the 19th. The Kensington case was from Ladbrook Hotel, O. S. A.

Chelsea Cases.—(1 and 2) One each from 44 and 38 Slaidburn Street, ¾ mile R., on the 8th and 18th. (3) One from 496, King's Road, ¾ mile R., on the 21st.

Thus the history of the cases recorded in the year 1879 clearly demonstrates the spread of small-pox in a common-place manner, and proves the speculative nature of the theory of the aërial dissemination of small-pox infection.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

EAST LONDON HOSPITAL FOR CHILDREN.

CASE OF TUBERCULAR MASSES IN THE NEIGHBOURHOOD OF THE LEFT FISSURE OF ROLANDO, WITH PARTIAL PARALYSIS OF RIGHT ARM: AND SUPERVENING TUBERCULAR MENINGITIS.

By H. B. DONKIN, M.B. Oxon., F.R.C.P.,
Physician to the Hospital.

John Barratt, aged four years, was admitted on the 7th of November, 1883.

With the exception of some bronchitis, for which he had been treated as out-patient for some months, he was apparently healthy till the beginning of September, when his right arm was noticed to move convulsively on several occasions, and he gave up using it, and became left handed—having been right handed before. He was said, by his mother, to cry when his left arm was moved at the time of his admission. Just before admission he fell from his chair one day, suddenly, without apparent cause.

Family history good. No evidence of phthisical or syphilitic history. When examined on admission he was a well-nourished, intelligent child. No complete paralysis anywhere, though he used his left arm much more readily than the right. No abnormality observed

in face. Slight wheezing over bases of lungs. Heart sounds natural.

On the night of the 9th of November he woke several times as if in severe pain, and on being questioned referred it to his dorsal spine; no tenderness there. The child seemed distressed.

November 12th.—Is in constant pain, putting his hand to his head, which he holds stiffly and retracted; was ordered twenty grains of bromide of potassium last night, without the production of much sleep; bowels very confined. Temperature in morning 100·4°, evening 98°.

15th.—Lies with his right hand under his head—face flushed, eyes closed, pupils dilated, tongue coated. *Tache cérébrale* easily produced. Complains of pain at the back of neck and head.

Bowels confined, fæcal lumps felt in abdomen. Skin of abdomen rather inelastic. Temperature about 100° a.m., and 97° p.m. Respiration regular, 35. Pulse regular, 144.

19th.—Has been in the same drowsy state. Bowels opened with difficulty by purgatives. At 4 a.m. temperature rose from 99° to 101°; death after a short convulsion.

The *post-mortem* examination was made by my colleague, Dr. Radcliffe Crocker, Pathologist to the Hospital, seven hours after the child's death. On removing the skull cap, we found some small, yellow, irregular patches on the left side of the upper surface of the brain, situated over the ascending parietal and frontal convolutions, and extending about one and a quarter inch from the median fissure: on cutting into them, there was found to be a chain of yellow masses, varying in size from that of a haricot bean to a millet seed: the central yellow mass was moderately firm, not softened, and was surrounded by a narrow pearly capsule. These masses shelled out easily from the brain and were connected together by a fibrous cord, apparently an obliterated vessel. The largest was about one inch from the median fissure, and situated on the anterior surface of the ascending parietal lobe. The smaller ones extended to about a quarter of an inch from the middle line on both sides of the fissure of Rolando.

On opening the ventricles, about two and a half ounces of serum escaped. On removing the brain, thick lymph was seen to cover the under surface from the posterior edge of the pons, up to the frontal lobes. The anterior edge of the right temporo-sphenoidal lobe was softened for an area about the size of a sixpence. The left slightly softened, not so much as the right. The lymph could be peeled off, leaving the under surface slightly soft, but otherwise healthy.

In the chest recent adhesions were found in the left pleura. The lungs were studded with grey granulations.

The mesenteric glands were caseous, but there was no lymph on the peritonæum.

The surface and interior of the liver presented numerous masses of tubercle: the larger masses on the surface dipping into the substance. A patch about three inches long and two inches broad shows signs of thickening of the capsule.

The spleen was stuffed with tubercular nodules; a few granules were found on the surface of each kidney, none in their substance.

This case is recorded as a probable example of a monoplegia of arm in connection with disease of the convolutions in the neighbourhood of the fissure of Rolando. The motor symptoms began with spasm and ended in a partial paralysis, after the manner of those supposed to be due to cortical lesions. The occurrence of the tubercle in the cortex was doubtless anterior in time to the meningitis which proved fatal. Whether or not there had been any paralysis of the right leg during life, as might have been expected from the involvement of the upper part of the ascending parietal convolution, it is impossible to say, as the child rapidly became too ill for thorough examination and the history was necessarily imperfect. On admission, both legs could be moved and the child could support himself on them and walk, though he seemed listless and inclined to remain quiet.

Medical Times and Gazette.

SATURDAY, JUNE 7, 1884.

THE International Medical Congress, which will be held at Copenhagen, from the 10th to the 16th of August, already bids fair to prove a striking success, if we may judge from the numerous applications for accommodation which have reached the Secretary-General. The patronage of His Majesty the King of Denmark will give due prestige to the gathering, and evidences are not wanting that the reception of the members of the Congress by all classes in Copenhagen will be marked by more than common hospitality. The representatives of their respective nations, who will deliver the chief addresses at the general meetings, have already published the subjects which they propose to deal with. We have already announced that Sir William Gull, who is to represent the views of the Collective Investigation Committee in London, will discuss the question of mutual investigation of diseases. Professor Virchow will speak on Metaplasia; Professor L. Pasteur, on Pathogenic Micro-organisms and Vaccine Material; Professor Tommasi Crudeli will deal with Malaria, and Professor Verneuil on the Neoplastic Diathesis, while Professor Panum, the distinguished President of the Congress, will deliver an address on Food rations, especially with regard to the inmates of hospitals and prisons. The absence of any American representative from this list is striking, but perhaps only temporary. The business of the various sections, as already settled, is considerable, as may be seen from the summary given below, and there are yet very many additions to be made. In the Section of Dermatology it is proposed to exhibit the various instruments employed in the surgery of the skin, examples of which may be forwarded to Herr Hyrop, instrument maker, in Copenhagen. At the end of the meeting an expedition to Bergen is projected, to permit of a visit to the leper districts in that neighbourhood.

THE arrangement of the sections follows pretty closely that adopted at the London Congress, with the exception that laryngology is to be raised from the subordinate position it occupied three years ago, while the subjects of Materia Medica and Odontology, which then had sections to themselves, are at Copenhagen to have neither a local habitation nor a name. In this we think the committee have been guided to a most wise decision. It is both unscientific and inconvenient to separate the consideration of the drug-cure, or indeed cure in any form, from the consideration of the phenomena with which it is inextricably bound up,

while the experience of the London Congress showed that the two or three papers of real scientific merit which would be likely to be delivered in a Dentists' Section, can be given much more advantageously in other sections. In the Anatomical Section there are many interesting subjects down for discussion, but there is no great show of English names. The same remark applies to the Section of Physiology, Dr. Burdon Sanderson being the only prominent countryman of ours who is announced to contribute to it. In the Pathological Section tuberculosis and bacteriology are, of course, given the foremost place; and Dr. Koch's paper on the "Morphological and Pathological variability of Pathogenic Bacteria"—at present the most pregnant of all subjects of scientific interest—will, no doubt, excite much attention. But the consideration of the pathology of chronic nephritis, to be introduced by Prof. Cornil and Sir W. Gull, will run neck and neck with it. In the Section of Medicine another subject which is just now deeply engaging medical thought, though as yet hardly ripe for discussion, viz., the operative opening of pulmonary cavities, will be introduced by Dr. Bull, of Christiania. Dr. Austin Flint and Prof. Grainger Stewart have papers in this section, and Sir Joseph Fayrer, in conjunction with Dr. Joseph Ewart, will call attention to that frequent legacy of a tropical life—obstinate diarrhœa, on which he has recently been writing. The same authority has a paper on another pet subject of his—Sunstroke—in the Section of Military Medicine. The first subject down for discussion in the Surgical Section is, of course, the Antiseptic Treatment, the various methods of which will have their advantages extolled by Sir Joseph Lister, M. Paul Bert, Prof. Esmarch and others. M. Paul Bert will also treat of Anæsthetics in Surgery, while Prof. Esmarch will join with Mr. Bryant and Prof. Verneuil in the discussion of operative treatment in Rectal Cancer. The use of the trephine in localised diseases of the brain will be discussed by Ferrier, Lucas-Championnière, and Mollière of Lyons. In the Obstetrical Section there are several important subjects down for consideration, but the only prominent British authorities as yet named in the programme are Mr. Knowsley Thornton, Mr. Lawson Tait, and Professor Simpson. Why this unwonted reticence?

The other sections must at present be content with even briefer mention. The subjects to be discussed by the ophthalmologists include the examination of the vision of railway servants and seamen, to be introduced respectively by M. Redard and Dr. Brailey, and Blennorrhœa neonatorum, a subject which is now engaging the attention of our Ophthalmological Society. In the Section of Children's Diseases Dr. Barlow has a paper on acute rickets, while in that of syphilis and dermatology the treatment of syphilis by mercurial inunction (papers by Liebreich and Lewin, of Berlin, Prof. Neumann, and Martineau, of Paris) will share attention with leprosy and lupus. Educational overpressure is down for discussion both in the Section of Nervous Diseases and in that of State Medicine. To the former section papers will be contributed by Charcot, Pitres, and Eulenberg, on various questions connected with spinal degeneration. In the programme of the Section of Laryngology all the best known names in connection with that specialty are down for contributions, including those of Voltolini, Mackenzie, Lewin, Fauvel, Schnitzler, Lefferts, Solis Cohen, and Felix Semon. Of the company of English aurists, Dr. Woakes is the only one as yet announced as a contributor to the Section of Otology. The Section of State Medicine will apparently be run almost entirely by Scandinavians; but Prof. de Chaumont will introduce a discussion on the prevention of scurvy. In the last section, that of Military Medicine, there will be a big discussion on Antiseptics in the Field, introduced by Prof. Esmarch, who will be seconded—with weight—by Sir W. MacCormac, a name familiar to all Congress-trotters. That discussion will no doubt be a field-day for all the Army Surgeons present.

To reach Copenhagen comfortably in time for the opening ceremony, England must be left not later than the evening of Thursday, August 7th. The traveller will then reach the Danish capital late on Saturday evening, and after a quiet Sunday will be recovered from sea-sickness and ready for work on the following day. The first thing to do is to get to Hamburg, which can be reached either direct by sea, or *viâ* Flushing, Ostend or Calais. From Hamburg there are two routes, one taking thirteen hours, six of them at sea; and the other twenty-five hours, all but two on terra-firma. The Reception Committee "wish to direct the attention of members to the necessity of providing in time lodgments for their stay in Copenhagen. The Committee offer their assistance in this regard, if members will apply before the 20th of July, at the very last, to the Secretary-General," Professor C. Lande.

The usual monthly meeting of the Obstetrical Society was held on Wednesday evening last. Several specimens were shown, some interesting, some commonplace. The chief occupation of the evening was the consideration of papers, first by Dr. Playfair, detailing two cases believed to be instances of pulmonary thrombosis in the puerperal state, which ended in recovery. The paper was criticised by Dr. Galabin, who thought the process in such cases was rather embolism than thrombosis; and by Dr. Wiltshire, who suggested that the diagnosis should have been ulcerative endocarditis. Dr. Playfair explained that the distance between the right auricle and the pulmonary artery was so short, that the plugging of the pulmonary artery by a clot formed in the auricle deserved to be called thrombosis, in opposition to the travelling of solid masses from distant parts into the veins, which was what he understood by the term embolism. The second paper was a contribution to the mechanism of labour, being on fœtal revolutions, by Dr. Matthews Duncan, and like all the work of that distinguished man, was marked by analytical power, exactness of reasoning, and scientific accuracy of statement. It was criticised by Dr. Galabin, from a purely geometrical point of view, his objections being replied to, partly by Dr. Champneys, partly by Dr. Duncan himself, in a speech of much animation.

The council of the West London Medico-Chirurgical Society have instituted an annual lecture to be called "The Cavendish Lecture." The first will be delivered on July 11th, at 8 p.m., by Mr. T. Holmes, with the title "Medical Attendance on the Poor of London."

The number of the *Compte-Rendu de l'Académie des Sciences* for May 5th, consisting of more than 100 pages, is nearly filled with an account of the prizes awarded for 1883, by the Académie, and the specifications of the future prize questions. The reports of the Committees of the various sections are published in full, setting forth the grounds upon which the prizes have been awarded, and emanating as they do from men of the highest eminence in their respective branches of science, they often form interesting and instructive reading. The prizes are numerous and of considerable value; but we can only refer to those of them which have a bearing on medical science. (1) The Barbier Prize, for a useful discovery relating to the art of healing, has been awarded to Professor J. Chatin, for his researches in the laboratory of Havre, on the *Trichina Spiralis* and Trichinosis, by which he is stated to have added considerably to our knowledge of the subject. (2) The Desmazières Prize has been assigned to MM. Bonnier and Maugin, for their researches on the Respiration and Transpiration of Fungi, an "encouragement" being also given to Professor Klein, of Buda-Pesth, for his researches on the Crystalloids of the Marine Algæ. (3) The Bordin Prize is awarded to M. Constantin, of Bordeaux, for his laborious experiments, continued over three years, on the Effects of Surrounding Media on the Structure of Vegetable Organisms. (4) The Grand Prix in Anatomy and Zoology has been given to Dr. Viallanes, for his great work, accompanied by an atlas, on the Histology of Insects, and on the Histological Phenomena which accompany their Post-embryonic Development. (5) For the Montyon Prize in Medicine and Surgery, the Academy adjudges three prizes of 2,500 francs each, viz., one to Dr. Constantin Paul, for his work on the Diagnosis and Treatment of Diseases of the Heart; another to Dr. Henri Roger, for his Clinical Researches on the Diseases of Infancy; and a third to Dr. Vallin, for his valuable Treatise on Disinfectants and Disinfection. "Honourable mentions," with 1,500 francs each, are also awarded to MM. Napias and Martin, for their "Progress of Hygiene in France from 1818 to 1882;" to MM. Dubar and Rémy, for their work on Absorption by the Peritoneum; and to Dr. Denucé, of Bordeaux, for his Clinical Treatise on Uterine Inversion. Moreover, the following "honourable citations" are also decreed, viz.:—to Dr. Berne, for his Lectures on General Surgical Pathology; to M. Certes, for his Micrographic Analysis of Waters; to Dr. Huchard, for his additions to Axenfeld's Treatise on the Neuroses; to Dr. Polaillon, for his Statistics of the Maternity at the Cochin Hospital; and to Dr. Rossignol, for his Treatise on Military Hygiene. (6) The Bréant Prize of 5,000 francs is decreed to Dr. Fauvel, for the various researches he has been engaged in on the Ætiology and Prophylaxis of Cholera, since the publication of his work on that subject in 1870, when he also obtained this prize. Moreover, the Academy proposes to divide the sum of 10,000 francs among the four pupils who are sent to Egypt, under the name of the "Pasteur Mission," as a recognition of their scientific devotion and of the important results which their courageous investigations led to. (7) The Godard Prize is given to Dr. Guelliot, for his Anatomy and Physiology of the Vesicul Seminales. A "honourable mention" is also given to Dr. Desnos, for his Lithotrity under Prolonged Sittings. (8) The Chaussier Prize is awarded to Dr. Legrand de Saulle, for his Medico-Legal Studies on Epilepsy and Hysteria; an honourable mention being also given to Dr. Layet, for his Hygiene and Disease of the Peasantry; and another to Dr. Luton, for his work on General and Special Therapeutics. (9) The Lallemand Prize has been divided between our respected contributor, Professor Ball, for his Lectures on Mental Diseases; and Dr. Voisin, for his Clinical Lectures on Mental and Nervous Diseases. (10) The Montyon Prize in Physiology is awarded to Professor Paul Regnard, for his Experimental Researches on the Pathological Variations in Respiratory Combustions. (11) The Lacaze Prize has been adjudged to Professor Balbiani, of the College of France, for his important series of researches in the most delicate and difficult question of Embryogeny and General Physiology, which have occupied him for more than twenty years, and are as remarkable for their precision in detail as for the philosophical bearing of their direction and results. The prize subjects will be adverted to in a future number.

At the meeting of the 16th of May, Professor Billroth showed to the Imperial Royal Society of Physicians of Vienna, a patient aged 29, who had an enormous osteosarcoma on the left arm. It extended from the sternum to the middle of the scapula; the outline of the scapula, however, could be distinctly felt through the tumour. At one point of the arm softening had taken place, and since that time the patient had complained of great pain. The operation for the removal of this enormous tumour, he pointed out, would be very hazardous, the patient being extremely weak. It would be necessary in such a case to ligature the subclavian, and even if the patient should survive the operation, such success would be only transitory, for metastases in the lungs often occurred in such tumours. Professor Dittel remarked that he had tried to operate, on the same day, on a tumour which bore some resemblance to that shown by Professor Billroth, but he was compelled to desist, as the extirpation of the tumour proved impossible. The scapula and the arm would have had to be removed, and another difficulty arose from the fact that there was no space between the tumour and the ribs, and that the vessels probably passed through the substance of the growth.

At the meeting of the same Society on May 23rd, Dr. Riehl, Assistant to Professor Kaposi in the clinic of dermatology, showed a man who suffered from "Erythrasma." This dermatomycosis was described about twenty-five years ago by Burghart and Bärensprung, but subsequently fell into oblivion, until Besnier, of Paris, recalled attention to it. It was

left to Balzar, however, to give a full and exact description of it. In many respects erythrasma is similar to pityriasis versicolor, the skin being stained with yellow or brown patches, easily denuded of their epidermis. They vary in form and their size is from that of a lentil to that of the palm of the hand. In contrast with pityriasis versicolor, however, the inflammation is here superficial, presenting itself as an erythema, and the affection is of longer duration. On examining the scales which have been scraped off from the patches, a fungus which bears great resemblance to "Microsporon furfurans" is found, namely: "Microsporon minutissimum." Erythrasma is usually met with on the scrotum, the inner parts of the thighs and in the axilla. In the man who was shown to the Society, the erythrasma stains were to be seen also in the front of the thighs and on the abdomen. Erythrasma is to be distinguished from Eczema marginatum by the fact that the process in the latter disease goes far deeper, and from Herpes tonsurans by its course. Herpes tonsurans has an acute course, and is moreover characterised by exudation into the epidermis. The treatment consists in killing the fungi and lifting off the epidermis; a complete cure is thus obtained in a comparatively short time.

The enterprising Director of the Berlin Polyclinic is desirous of introducing an innovation in Medical education. As may be seen from his announcement in our advertisement columns, he is prepared to appoint English graduates as assistant teachers in their various specialties. We are a little doubtful if this will work on any very extensive scale, but if it succeeds, a much needed opportunity will be presented to would-be instructors of gaining experience both in instruction and practice.

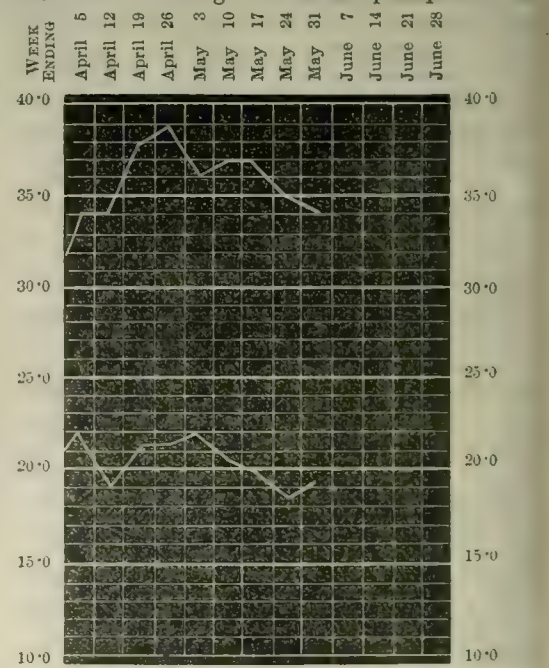
The Universities of Prague and Gratz have each recently established special chairs for hygiene, both of which are filled by pupils of Pettenkofer. Dr. Soyka, of Munich, has been nominated Professor at Prague, and Privat-docent Gruber at Gratz.

For the pursuit of bacterial investigation, which of late has acquired such an increased importance, the Berlin *Reichsgesundheitsamt* has hitherto been the only place in Germany that has offered any facilities for research; and here only a limited number of persons were enabled to familiarise themselves with Koch's methods. Professor Bollinger has the merit, then, of first establishing in a university an institute at which bacterial courses of instruction can be undertaken. A short time since he was the means of founding in the Munich Pathological Institute a new laboratory for bacterial investigations, where already a bacterial course of lectures has been commenced for young docenten of the medical faculty, under the direction of Dr. Frobelius, an assistant of the institute.

It may be of interest to those who are coveting the honour of examining the aspirants to a medical degree, to learn that Dr. James Anderson, Examiner in Physiology and Natural History in the University of Aberdeen, and Examiner also at the College of Physicians, London, has had to resign the Aberdeen appointment before the natural end, in September, of his term of office. This has happened owing to an overlapping of the periods of the next July examinations held by the two bodies; and the Aberdeen authorities will consequently have to make a new appointment forthwith.

The Annual Report of the Metropolitan Board of Works, for 1883, is now before us, and contains a vast amount of information of all sorts. During the past year about 14,000*l.* have been spent in cleansing the 250 miles of main and intercepting sewers, by means of which the sewage of London attempts to get carried away, and more than ten times that amount has been spent on new sewers. Under the Labourers and Artizans' Dwellings Acts, the Board have submitted to Parliament no less than eighteen schemes, involving the displacement of 23,414 persons, but as yet dwellings have only been erected to accommodate about half that number. Since 1882 the Board have been unusually vigorous in regard to the structural defects of the theatres, and at the end of that year there were but six with which they had fault to find. The owners of the others have, after some show of resistance, in almost every instance complied with all the requirements of the Board.

The London death-rate rose again last week to 19·2, the deaths being 22 below the ten years' average. The deaths from small-pox showed a marked increase while those from measles and whooping-cough were less than they had been for some weeks. In spite of this, the total number of deaths from zymotic diseases was 27 above the average. The small-pox epidemic is



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the first nine weeks of the present quarter.

still spreading; the hospitals admitted 370 new cases during the week, and on Saturday had 1,057 cases under treatment. The deaths from diseases of the respiratory organs experienced a slight fall and were 15 below the average.

The annual dinner of the Cambridge Medical Graduates' Club will take place on Tuesday, July 1st, at the Marlborough Rooms, 307, Regent Street, Professor Humphry in the chair. Graduates who have received an invitation to join the Club and have not yet done so, should communicate with either of the honorary secretaries, Dr. Fowler, 35, Clarges Street, Mayfair, W.; or Dr. Steavenson, 15, Henrietta Street, Cavendish Square, W.

Mr. Jonathan Hutchinson will deliver a series of lectures at the London Hospital, on Mondays and Wednesdays, at 4 p.m., commencing on June 25th. The subjects he has chosen for this course are, calculi and their lessons, the urinary diathesis, the early recognition of cancer, gout as a surgical disease, certain clinical groups of tumours and congenital syphilis in relation to chronic skin diseases.

We regret to announce the sudden death of Mr. Stannus Hughes, of Dublin, which occurred somewhat unexpectedly early on the morning of Whitsun-Day, June 1. The day previous to his death, Mr. Hughes attended the annual meeting of the Fellows of the Royal College of Surgeons in Ireland, but his many friends had been for some time anxious about his health, as his appearance was far from reassuring. However, he continued to discharge his many professional duties with uninterrupted zeal, and he may be said to have died literally in harness. So far back as 1838 Mr. Hughes became a Licentiate of the Royal College of Surgeons in Ireland, proceeding to the Fellowship in 1844. In 1864 he graduated as Doctor of Medicine in the Queen's University. He filled in time many posts of dignity and responsibility in his profession. He was for a period an Examiner in Surgery in his own University. He was up to his death a Surgeon to Jervis Street Hospital, and also to the Convalescent Home, Stillorgan, Co. Dublin, as well as Consulting Surgeon to the Coombe Lying-in Hospital. He shared with Professor William Stokes the Chair of Surgery in the School of the Royal College of Surgeons, and for many years he courteously and efficiently discharged the duties of Surgeon in Ordinary to the Lord Lieutenant's Household, Dublin Castle. As Secretary to Council of the Royal College of Surgeons, James Stannus Hughes won the respect and confidence of his professional brethren, by whom his memory will long be cherished.

The new method of administering ether by the rectum has been warmly welcomed in the United States, and several trials have been successfully made. (*New York Medical Record*, May 3rd, and *Boston Medical Journal*, May 8th). In the former of these journals, however, a timely caution is given, for not only is it stated that a fatal case has already occurred, but it is also pointed out that the degree of etherisation is not always well under control, nor can its administration be promptly arrested. Moreover, many patients suffer from intestinal irritation as a consequence of the procedure. The rapidity with which the ether is absorbed is remarkable, some patients tasting it within two minutes after the introduction of the rectal tube. The general anæsthetic effect is not so rapidly produced, but the administration is much less annoying to patients, while they recover more speedily than after ordinary etherisation, and manifest less subsequent excitement. "The new method is neither applicable nor necessary in prolonged operations. Even in those upon the face and throat, anæsthesia by the rectal tube need only be alternated with that by the cone in a large range of cases. Indeed, in all severe and prolonged operations upon the face, a hypodermic injection of 8 or 10 minims of Magendie's solution of morphine, given a few minutes before cone-etherisation is commenced, is sufficient, in a large majority of cases, not only to tide over the intervals when the mouth must be free, but to enable the operator to dispense with the ether altogether for varying periods. In most nervous persons, it may be found advantageous to commence etherisation by the rectum until unconsciousness is produced, when the anæsthetic effect can be maintained by the cone with the usual surety and safety. But, as we have already remarked, the range of applicability of the rectal method must be determined by time and experience."

The spirit of mockery and raillery is still rampant in certain American journals, making harvest out of the march of progress in modern surgery. The *Medical Record* of New York wastes two columns in laborious attempts to prove that since the "quite modern surgeon is a bold, bold man thoroughly imbued with the spirit of iconoclastic radicalism," every organ must in turn acknowledge his potent sway and submit to resection or excision, until apparently little or nothing remains. "The problem of the hour is to determine exactly with how few organs, or with what minimum remnant of these, the vital functions may continue to be performed long enough for the publication of the individual case, as illustrating a new triumph of operative skill." And the article concludes thus: "Shall there be no further dawn of new light for the operator? Shall his keen blade rust until a tumour actually forms? By no means. Let him rather be the destiny that shapes our ends to suit modern requirements." It is extremely difficult to know in what terms to speak of trifling such as this in the editorial columns of a medical journal. Few surgeons are likely to be encouraged to deal with difficult cases by scornful criticism of this nature. An occasional joke at our expense in a professedly comic paper can be tolerated or laughed at; but the case is different when the strivings of the profession are so hopelessly held up to ridicule by those whose duty it should be to chronicle innovations and to criticise them fairly and soberly.

What is to be done with our small-pox patients? This is an ever recurring question, thanks in great

measure to the superior wisdom and more intelligent enlightenment of a small knot of individuals who know a great deal more than the rest of us. The dwellers in London are never tired of pointing out the great advantages that small-pox patients would derive from treatment in the country, whilst those who reside in the suburbs are at least equally eloquent on the dangers and difficulties of transporting them so far, and can produce half a score of reasons why the patients should be treated in the metropolis. Between the two the difficulty of providing sufficient accomodation is a very real one, and every year seems to find an increase in the obstacles to be overcome instead of seeing the difficulties gradually smoothed away. The present epidemic affords to the anti-vaccinators an opportunity which, we hope, they will avail themselves of. It is simply this. Many, probably almost all of them, have never seen the inside of a small-pox hospital; now is their chance, there must be plenty of room for extra nurses both male and female. Let some of them volunteer then without delay for this work; they will thus be able to test practically whether vaccination is of any use, and if they will, after a time, press all their fellow believers, or rather unbelievers, into the service, they will have the satisfaction of learning afterwards that they adopted the most efficacious means of stamping out the disease.

The indignant complaint addressed last week to a daily journal, by Mr. Gillham, the Secretary of the Princess Louise Home of the National Society for the Protection of Young Girls, with reference to the difficulties he encountered in procuring the removal from the home of some of the inmates when stricken with small-pox, accentuates the importance of two very different subjects which are coming on for discussion in two very different assemblies. The one subject is that of Metropolitan Government, which will shortly engage the attention of the House of Commons; the other has reference to the means of preventing the communication of small-pox, which is to be discussed, we believe, both at the Annual Meeting of the British Medical Association, and at the Copenhagen Congress. Mr. Gillham appears to have spared no energy in his attempts to get rid of his infectious inmates, but he was driven from pillar to post in a manner that would be ludicrous to read of, were it not so shameful, and a whole week was lost before he could gain his end. Of course by that time "the girls were sickening right and left; and from that day to this they have been drifting into the hospital by twos and threes." If the facts attested by Mr. Gillham are not explained, no better means of strengthening Sir W. Harcourt's hands in his efforts to pass his Metropolitan Bill could be devised than to print Mr. Gillham's letter by thousands and scatter it broadcast throughout London. That would shake the hitherto unshaken complacency of the vestries. This official recklessness with respect to small-pox is no new thing, as anyone who reads the elaborate articles by Mr. Makuna, that we are now publishing, will be able to convince himself. It seems absurd to sit down and debate about the aërial communication of small-pox, when so many opportunities of communication by close contact are, by the indolence and red-tapeism of the authorities, still left in existence.

Dr. Jaggard in concluding some papers in the *Philadelphia Medical News*, April 26, on the Pathology, Ætiology, and Prophylaxis of Puerperal Fever from the Vienna Stand-point, furnishes the following statistics in proof of the great efficacy which has attended the prophylactic measures employed since 1862. From 1847 to 1862, there were treated in the Vienna Obstetric Clinic 64,500 cases of labour, with a mortality of 3·45 per cent.; and, from 1862 to 1878, in Carl Braun's wards there have been 61,949 cases, with a mortality of 1·65 per cent. Since 1878, the results have been still more favourable, so that, at the present time, the mortality rate from puerperal fever in Carl Braun's wards clinic is one half per cent. During the winter quarter of 1883, among some 900 cases of labour, no death resulted from puerperal fever. These statistics, Dr. Jaggard states, have been most conscientiously and accurately compiled, and there can be no reasonable doubt as to their absolutely truthful character.

THE REVOLT OF THE PHYSICIANS.

The large affirmative vote given last week by the Fellows of the Royal College of Physicians, on Dr. Andrew's bold and popular resolution to refer to the Council their list of nominees to the Fellowship, has a significance as great as its intrinsic wholesomeness and importance. Of the advantage of this vote there may be said to be practically but one opinion. It emphasised in an unmistakable manner the determination of the Fellows that the traditional qualifications for entry into their much-coveted inner circle should be jealously guarded, and that while mere professional success must look elsewhere for its crown, the Fellowship must not be indefinitely withheld from those younger workers in what is called the higher rank of the profession, who, being personally worthy, have been taught to regard this honour as a compensation in some degree for the deferred pecuniary reward attaching to their chosen career. But over and above this, the vote has shown to the Fellows the potential strength of the popular element in the College, and should encourage them to endeavour to bring about certain reforms which would realise and consolidate the powers they already have, while practically adding others which they may now rightly claim as having shown themselves the truest guardians of the honour and dignity of their College.

In the first place it would seem to be highly desirable that active interest should take the place of the undoubted apathy that now exists among the Fellows with regard to the election of Members of the Council. That body is now, to all intents and purposes, a co-opting one, for it is rarely, if ever, that an outsider ventures to propose an amendment to the House-list of fresh Councillors which is annually laid before the Fellows. Were the College generally to bring a serious mind to this business, which is usually transacted in a few formal minutes, it would be scarcely possible that such an occurrence could take place as the recent practical rejection of the Council's tale of nominees

to the Fellowship; for a Council which was *in esse* as well as *in posse* the Committee of the general body would have too good a touch of the prevailing feeling as to the proper recipients of the honour to err so widely as on more than one occasion the present constitution has permitted. Not only in the matter of election to the Fellowship, but in nearly all the business of the College a truly representative Council is an obvious desideratum; and the more perfect the realisation of this object becomes, the less danger there will be of oligarchical or even despotic rule.

But this increased activity on the part of the College in using the powers it already has, is not all that we think desirable to ensure its welfare and to keep intact the present high standard of the rank of Fellow. A Council, however constructed, must be far from infallibility or omniscience, and on such an important matter as the nomination of Fellows, should not be left so unrestricted and unaided as it virtually is at present. It is unlikely that the true feeling of the College as to the fit and proper candidates for the Fellowship will ever be allowed free expression until the nomination of these candidates be placed in the hands of the Fellows at large, to be fully and faithfully dealt with by the Council. We would suggest that the College of Physicians should follow the example of the Royal Society, and commission its Council to prepare each year a list of Fellows-designate from among those whose names have been proposed and supported by the Fellows with a full statement of their claims and qualifications; and that before the Council issue their selected list, the names and qualifications of all candidates should be placed in a printed form in the hands of the Fellows. The Council's list thus chosen would be practically final, subject only to the possible rejection of individual candidates by the general body. The Fellows' power at present in the matter of election to their own body is almost *nil*. They can add no names to the Council's list of nominees, and the majority which is requisite to black-ball a candidate reduces their power of veto to a minimum of effect, unless the case be a crying one. But the remedies we propose would both ensure the existence of a Council in which the fullest confidence could be placed, and afford every facility for all just claims to be considered; so that even if the method of black-balling, at present nominally in vogue though but rarely brought into actual play, were to remain unaltered, the 'corporate conscience of the College, which we rejoice to believe is very tender, would be almost secure from injury, and its dignity would be beyond the risk of injury.

PNEUMOTOMY.

We reported last week some interesting cases in which pus-secreting cavities in the lungs had been opened and drained externally with considerable success. The record of such a bold and novel proceeding is well worthy a little special attention, for it deals with an organ which, until very lately, has been considered sacred, and beyond the reach of the surgeon's knife. It is quite true, as Mr. Gould has pointed out, that Richter, an eminent German surgeon of the last century, prophesied that the day would come when such abscesses would be so treated; but much work had to be done first, and it is not difficult to see why it has been reserved for surgeons of to-day to successfully plan and carry out Richter's idea. The discussion at the Royal Medical and Chirurgical Society followed the reading of a case in which this operation had been successfully accomplished by Mr. Gould, at the suggestion of Dr. Cayley. The patient was a girl about twelve years of age, suffering from a local gangrene of the lung of acute onset: other remedies had failed and the girl was rapidly losing ground, when it was decided to puncture the lung and endeavour to drain the cavity of its gangrenous contents. So successfully was this accomplished, that a sequestrum of gangrenous lung was evacuated, and the patient made an excellent recovery. Dr. Biss subsequently related a case in which a basic abscess, with fœtid contents, had been diagnosed and a similar plan of treatment carried out by Mr. Marshall. The case was of a more chronic nature than the preceding and not so easy of diagnosis. As might have been anticipated, it was less successful, but nevertheless the operation afforded the patient considerable relief during the short remainder of his life, and death was in no sense due to the operative measures adopted. In the discussion which followed the reading of these papers, several other cases were mentioned. Dr. Fowler gave the particulars of a very unusual case, that of a man who had accidentally swallowed a molar tooth. Disease of the lung, with formation of a cavity in the base, supervened, and threatened to prove fatal. Here was a double indication, not only to drain the abscess, but if possible to get out the tooth, and though the latter object was not accomplished, in respect to the former a fair amount of success was obtained. Mr. Godlee related cases in point, as did Dr. Broadbent and Mr. Walsham. In all alike, the advantages of freely draining away the pus were manifest, even when, from the nature of the case, a permanent cure was not attainable.

The operation consists in opening the abscess cavity, and putting in a drainage tube. It is variously done, either with or without previously incising the chest wall. Thus Mr. Gould passed in a large trocar and cannula, and after withdrawing the trocar, introduced a drainage tube and then withdrew the cannula, leaving the tube in the cavity. Mr. Marshall cut down on the pleura, and after exposing it, pushed in his trocar to the depth of four inches. Mr. Godlee, in his cases, excised portions of ribs, and used a scalpel, after having explored with a hollow needle in the first instance. The amount of hæmorrhage appeared to vary, but in none of the cases was it severe, and in none was there any difficulty in arresting it. As regards the pleural cavity, while most of the speakers agreed that it would be better if it had been obliterated by adhesion, some seemed to think that the importance of its obliteration had been exaggerated. At this stage we must abstain from expressing any very decided views on the above questions. On *à priori* grounds, we should incline to use a trocar and cannula in preference to a knife, as being less likely to lead to severe hæmorrhage; and on the question whether obliteration of the pleura is

essential or not, we should decidedly lean to the view that a healthy pleural cavity—could it be diagnosed—would be a strong contra-indication, for it can hardly be doubted that the accidental introduction even of small portions of gangrenous fluid into a healthy pleural cavity, would be followed by severe inflammation, and possibly by gangrenous empyema. Indeed such a case has quite recently come within our knowledge. On the other hand, every pathologist knows that the pleura is often unaffected, even when the adjoining lung is markedly diseased.

The number of cases in which the operation has been performed is certainly very small, but it is sufficiently large to show its practicability, its freedom from undue risks, and its appropriateness in some cases. Can we deduce any conclusions from the evidence before us, either as to the class of cases, or the mode of operating? Dr. Cayley's case was one of acute gangrene, following, or rather associated with, general pyæmia, and the result was eminently satisfactory. Dr. Biss's case, like the other cases mentioned in the discussion, was of a much more chronic nature, and two physicians differently interpreted the physical signs with which it was accompanied. The inferences, it seems to us, are sufficiently obvious. An acute process—that is to say, probably a very localised one—is more likely to get permanent benefit than a chronic disease which possibly may already have spread beyond the region chiefly affected, and therefore ceased to be a local disease, such as might reasonably be expected to yield to local measures. Moreover, the uncertainty in the diagnosis is a factor of no mean importance, and Mr. Godlee's suggestion that physicians should especially devote themselves to the "fine art" of diagnosing cavities is not without force, Dr. Powell's disclaimer notwithstanding. So soon as this heroic treatment of cavities in the lungs comes to be recognised as within the domain of legitimate surgery, physicians will doubtless lay down rules for their detection, though surgeons, we hope, will not fail to educate themselves to a proper level, so as to speak with as much authority on abscess in this organ as when it occurs elsewhere, thus rendering themselves, if not independent of the physician, at all events capable of forming an unbiassed opinion on the desirability or otherwise of surgical interference. The mode of operating is one which cannot be dogmatically laid down—experience alone will decide whether a trocar or a knife shall be used. Analogies, however, come to the rescue, and point to the use of the trocar. The lung differs widely from the liver for instance, in that it is collapsible; hence in the middle of an operation, as the vesicles empty themselves, and as the abscess cavity contracts, the lung will tend more and more to recede from the surgeon's grasp, and hæmorrhage may thus become very difficult to arrest. Perhaps means will be found for laying bare large areas by removing portions of chest wall, but until this is accomplished it appears to us that cutting operations deep into the substance of the lobes had better be avoided. Mr. Gould's successful case, moreover, shows what may be accomplished by simpler and safer methods. In the case of a foreign body, this argument would apply with less force; but even then, the preliminary use of a long fine needle for exploring purposes—as is done in the case of the kidney—seems to us desirable. Meanwhile, we can only congratulate surgeons on this further advance in their art, and trust that pneumotomy will shortly be established on a broad and secure basis.

A HOTBED OF QUACKERY.

To judge from the local distribution of Medical Defence Associations, and from the quarters which advertising quacks and their tract distributors single out for their happy hunting-grounds, one would think that quackery was a plant that could only flourish in a poor soil. Such a conclusion, however, would be erroneous, as the more astute and better educated quacks could tell you, if they would. They could point out country houses, and London mansions, where their cleverly contrived doctrines find a readier credence, and their pilules and decoctions a readier sale than in villa or cottage. Of course they have to put a very different bait on their hook from that which succeeds in Bermondsey and Limehouse. Indeed, the quack who directs his attention to the West-end would probably disdain an East-end practice; possibly he would not succeed in it if he tried. He knows his *mêtier*. He has to deal with more or less intelligent people, educated up to a certain point, and possessed with an overweening idea of their own cleverness and culture, superstitious, but in most cases devout and entirely well-meaning, kind and charitable. It is obvious that with such a class mere assertion will not go down as it does amongst the lower orders. The quack who appeals to Belgravia and Mayfair must have a plausible theory to propound, and he must not be more ignorant of physiology than his patients. He must contrive to touch their religious feelings, here and there deftly introducing an argument from design. This, however, must be cleverly done, without too apparent cant or vulgarity, for his prey is suspicious and easily shocked. If, further, he can aver, truthfully or otherwise, that he is a man of birth and culture, his success is assured. It adds of course immensely to his chances if he honestly believes in himself—and we grant that many quacks do believe in themselves to a certain extent—for the delicate *nuances* of the part are much better rendered by one who identifies himself with it than by one who is only a mercenary actor.

One of the chief irregular practitioners of the day, whose name is familiar from advertisements at railway stations, and whose writings are read with intelligent appreciation in West-end drawing-rooms—a certain Count Cesare Mattei, of Bologna—corresponds faithfully with the above description. A man of birth and property, we are informed, he had already entered middle life when it occurred to him that the medical science of the day was a fraud. Doctors worked industriously enough at disease, and talked glibly enough about it, but they did not cure it, and often did not even profess to cure it. Now, argued the Count, Providence would certainly not have visited us with so many diseases without at the same time providing us with their appropriate remedies. Hence,

he was led to ransack the woods and pastures of Italy for simples, and at last he found two different substances, with which he affirms that he can cure all diseases, even the most pernicious cancer yielding and often "shelling out" on the application of his remedies. He has cured thousands, he tells us, in different cities in Italy, who had been given up by orthodox medicine, and for many years he has maintained out of his own funds a hospital at Bologna, for the treatment of the poor. But a system, to take with the educated classes, must make some show of science, and Count Mattei has not been blind to this means of extending his sphere of usefulness. He is distinctly a humoral pathologist. There are two main fluids in the body, blood and lymph, and all diseases arise from the perversion of one or both; there are also two main remedies, and if your disease will not yield to "anti-limfatico," it will assuredly succumb to "anti-angiotico." The Count has associates in various countries, who, for a consideration, will advise as to which remedy should be used. His chief representative in this country is, we believe, a French gentleman, who divides his time between vending wines and advising patients. Here then we have all the conditions necessary for a successful system. An aged and benevolent gentleman with a title, who spends his life and substance in succouring the poor, and who, we do not doubt, is honestly convinced of the value of his discovery, and the efficiency of his efforts; a theory sufficiently plausible to take in those whose smattering of knowledge, combined with hereditary assurance, gives them an overweening confidence in their own powers of reasoning; and lastly, as the salt cunningly sprinkled on this salad of science and sentiment, comes in the teleological argument. With all this to recommend him, it is not to be wondered at if the name of the author of the new "electro-homœopathy" is mentioned with sympathetic respect in many an aristocratic home.

There is another name which has recently acquired almost equal vogue amongst the superstitious. It is that of an ex-lieutenant of the Swedish army, who, impressed by the results of the Zander system, came to London a few years back, with the view of carrying it out on English patients in a modified form. He now occupies a large house in one of the best West-end squares, and the number of patients who daily submit to the manipulations of his myrmidons is described as very considerable. His system is different from Mattei's, but, from what one hears, is scarcely less successful. At any rate, if the one cannot cure you, the other infallibly will. "The Count" attacks you from within, but "the Swede's" assault is from without. He will knead your head for epilepsy, pummel you for locomotor ataxy, tweak you for paralysis, and in fact manipulate you for any and every disease. He, too, has a plausible theory, and is in a position to appeal with success to the wealthy and so-called educated classes. He does not appear to be so disinterested as the Count, whose charge for his panaceas is within the reach of the poorest pocket; but then the Swede has an expensive establishment of shampooers and massagers to keep up, and you cannot expect to get so much expenditure of skilled manual labour without paying for a corresponding amount of beef and beer.

We have, perhaps, gone out of our way to give a few details of these princes of the irregular profession, but we hope it may be some consolation to the poor "regulars" who groan under the competition of the herbalist and prescribing chemist, to hear that their consultant brethren in the West-end have not the whole field to themselves. We have not, however, as yet heard of any proposal to prosecute, or, indeed, of any serious complaint of the rivalry of, these successful Mahdi's. And, we presume, for this reason. The honest, regular practitioner invariably finds that his patients come back to him after a certain period of trial culminating in disappointment. In fact, no quackery that the world has yet seen can ever long compete with conscientious and honest practice. It is, we believe, the assumption by certain regular practitioners of greater knowledge and skill than they possess—quackery in fact—that drives people to irregular practitioners. If doctors would never try to make people think they know more than they do, but would honestly confess their ignorance when they are puzzled, their patients would have less reason to confound them with irregular practitioners, and less temptation to fly from the one to the other. We do not for a moment either believe or contend that the doctors of the poor are less honest than the doctors of the rich, but they are certainly less highly skilled in their profession; and the man who is not fully assured that he possesses all the available knowledge and skill in his profession, is much more exposed to the temptation of concealing his ignorance than the man who has the right to regard himself as an authority. We feel sure that the true method of dealing with quacks is to be found, not in prosecutions by Medical Defence Associations—which, to our mind, are always more or less a confession of incompetence—but in the higher training of the profession generally in science and morality.

REVIEWS AND NOTICES OF BOOKS.

THE REPORT OF THE MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD.[1]

A COMPARISON between the official Report of the Medical Officer to the Local Government Board and that of the Medical Officer of the German Board of Health involuntarily suggests itself when one peruses the recently-issued "Supplement containing the Report of the Medical Officer for 1882." Putting on one side the attractions of the German quarto sheet, good binding, and lavish illustrations, it must be confessed that the scientific matter in the English volume, taken as a whole, is inferior in quantity and in value to that contained in the pages edited by Dr. Struck. This is the more to be regretted because it is not attributable to any lack of ability, knowledge, or power of investigation among English workers, but to the small staff

[1] The Twelfth Annual Report of the Local Government Board, 1882-1883. Supplement containing the Report of the Medical Officer for 1882. London. Hansard. 1884.

which successive Governments with a false economy employ in original investigation.

The present volume contains the usual information as to vaccination, and something more. The Vaccination Acts throughout England and Wales have been carried out so efficiently as only to leave unvaccinated 47 out of every thousand children born ; the total result is of course the sum of very unequal factors; in London, for example, no less than 70 per thousand escape ; and this is in part an explanation of the persistence of variola in the metropolis.

The important discovery has been made that it is possible for syphilis to impart its malignant property to vaccine lymph. We would that the fact had been established accidentally and not as the result of a formal auto-experiment. Dr. Cory deliberately caused himself to be inoculated with vaccine lymph, derived at four different dates, between 1877 and 1881, from emaciated blotched infants, severely and unmistakably syphilitic ; the last experiment, made on July 6th, 1881, was successful, and twenty-one days after, local papules formed ; subsequently the axillary glands became affected, and constitutional symptoms fully developed. Dr. Buchanan remarks on the relation of the case to English vaccination. "In the outcome Dr. Cory's result has a certain pathological interest. The lymph of a vaccine vesicle upon an actively syphilitic may, it would appear (though under limited conditions that remain obscure), contain the virus of syphilis, even when there is no recognised admixture with the lymph of matters foreign to it. But that is all. For it was needful for the purpose of Dr. Cory's experiments that he should throw aside two rules which habitually guide him as they guide other people in the practice of vaccination. He had to take, and he did take intentionally, lymph from children with strongly marked manifestations of syphilis, one of which manifestations was a pronounced skin disease. This abandonment of vaccination rules would appear furthermore to have been of the essence of his success in transmitting syphilis. Dr. Cory's result, therefore, does not give any new rule for the guidance of the practitioner. For the practising vaccinator the obligation will remain neither weakened nor strengthened to 'Take lymph only from subjects who are in good health,' and 'Always carefully examine the subject as to any existing skin disease, and especially as to any sign of hereditary syphilis' (Board's instructions to public vaccinators). And the result of Dr. Cory's experiment, in which this rule of practice was necessarily disregarded, does not at all affect the conclusion derived from long-continued experience of properly conducted vaccinations, that the observance of the above rule is in practice a sufficient safeguard against the transmission of syphilis." In agreeing generally with this exposition, nevertheless we think it does not accentuate sufficiently the momentous import of the unfortunate experiment, which is, that the old doctrine faithfully held by the majority that vaccine lymph free from blood will under no circumstances be the vehicle of infection, is erroneous. It follows that vaccinators have a greater responsibility than ever in vaccinating from human vaccinifers ; we therefore turn to the report of the establishment and operations of the Animal Vaccine Establishment, an institution likely, under the circumstances, to satisfy an increasing public demand for animal rather than human vaccine. Mr. Shirley Murphy tells us that permanent premises were opened in Lamb's Conduit Street in the early part of April, 1882, and that every Tuesday and Thursday, from 10.30 to 12 noon, vaccination of adults and children direct from the calf is performed. Accompanying the report are plans of the premises, and an elaborate table giving various details relative to the calves, and as to the origin and descent of the lymph. The extremely satisfactory conclusion is drawn, "that, judged by the experience gained during the first year's operation at the Animal Vaccine Establishment, animal lymph 'takes' with as much certainty as humanised, and produces similar local and constitutional effects."

The circumstances leading to the reports of Mr. Power on diphtheria in Pirbright, and enteric fever at Norwood, those of Dr. Barry on the Bangor outbreak, and of Dr. Blaxall, on enteric fever at Sherborne, abound with interest, and will be studied with advantage. A report by Mr. Power on the outbreak of scarlet fever in the parishes of St. Giles' and St. Pancras contains the germ of a fresh point of departure, which may change entirely our views as to the ætiology of the disease. Dr. Klein made experiments first as to whether the lochial discharges of a reputedly healthy cow could when inoculated into, or administered along with food to, certain other animals produce in them any obvious illness, but these experiments all, without exception, gave negative results. He next inoculated a cow with desquamated cuticle from a scarlet fever patient ; this also gave a negative result, but inoculation with muco-purulent matter from a scarlatina throat, developed in ten or eleven days a local abscess, without general fever, and a drop of pus from the abscess caused, when inoculated into a dog, general fever and local mischief quite distinct from that which could be produced by ordinary pus.

The most striking experiment was, however, that upon a cow already in bad health, which had recently calved. Muco-purulent matter from a scarlatina patient was injected into the subcutaneous tissue of this animal and also poured down its throat ; only a local abscess formed, which soon healed ; nevertheless the lochial discharges of this animal mixed with milk and subcutaneously injected into two dogs gave a distinct febrile disorder ; and in one of the dogs, the throat became inflamed. The import of the experiment may be summed up as follows : The secretions of a cow recently calved, after the animal has been inoculated with scarlet fever, are in no way different from what they were before ; when the secretions are inoculated into other animals they produce a disease at all events analogous if not identical with scarlet fever, the cow during all this period not being visibly affected in health. Whether the cow is ever without inoculation in what may be called a "crypto-scarlatinal" state, and whether the milk of such a cow when drunk by the human race is capable of producing any disease, is at present unknown.

The report of Dr. F. H. Blaxall on the sanitary aspects of emigration and immigration abounds with so many details relative to the accommodation in various vessels, and is so clearly and simply written that it might advantageously be published in a separate form so as to be more accessible to the public generally.

Our knowledge of the practical aspects of the anthrax bacillus and the clinical symptoms by which its incidence may be recognised in man, is extended by the enquiry of Mr. John Spear on the occurrence of anthrax amongst persons engaged in the London hide and skin trades. It appears that, from the hide warehouses and tanyards of the Bermondsey district, occasional cases of malignant pustule have been admitted, and the cases now recorded appear to be specially connected with particular consignments of ox hides. In connection with anthrax, Dr. Klein has continued his investigations on its growth, culture, and decay. He has also investigated Pasteur's assertions relative to attenuation of the virus, but has been unable to confirm them. Even tubes of protective anthrax vaccine obtained from M. Boutroux (M. Pasteur's agent) were either harmless, producing no result, or so virulent as not to vaccinate but to kill. We fear that M. Pasteur's vivid imagination carries him sometimes

beyond the strict dogma of fact. He has recently in the same way brought out a protective vaccine for rabies, which candidly we must look upon with the gravest suspicion, especially as, considering the uncertain and prolonged period of incubation, one man's lifetime is insufficient to place the protection or non-protection of animals or men from inoculated rabies on an experimental basis. Before leaving the subject of anthrax we note that Dr. Klein found on using the blood of a mouse dead of anthrax, that a slight illness could be produced in sheep, after which virulent anthrax could be inoculated in the same sheep without effect. The interesting volume concludes with one of those profound researches on the chemistry of the brain, which only Dr. Thudichum can make; but this paper must be reserved for a separate article.

Elements of Surgical Pathology; by AUGUSTUS J. PEPPER, M.S., M.B. Lond., F.R.C.S. Eng. London: Cassell & Co., 1883.—Surgical pathology includes the whole of general and by far the greater part of special pathology. Consequently we find in the book under notice —Inflammation and its Results; Fever and the Infective Diseases of Wounds; Tubercle and Syphilis; the Degenerations; Union of Wounds; Fractures; Atrophy, Hypertrophy, and Tumours. Each system also is taken, and a few words said about the most important diseases and results of injury affecting it. The book is a small one, but it really contains a large amount of valuable information conveyed in a pleasant style. Still it is by no means uniformly reliable. The writer is evidently most at home when he can approach a subject from the clinical side, or demonstrate its naked-eye pathology; and as he does this to a large extent, we believe that the book will prove useful to the student. But on many points in general pathology we cannot help thinking that the author has not kept himself abreast of the times. It is generally held that an accurate knowledge of the process and ætiology of inflammation is the foundation of surgery; and yet this subject is treated in a very few pages, and, as we believe, most unsatisfactorily. Indeed, we had difficulty, after reading the first chapter, in seeing the good which really lies in ensuing ones. The following extracts will enable readers to judge whether censure is justifiable. Having stated in the first paragraph that living tissues possess the property of "irritability," and that this is most marked in those tissues in which new cells are being constantly produced, the author proceeds to demonstrate the necessarily destructive nature of inflammation (which the student now hears of for the first time) thus: "This increase of activity, whether showing itself by enlargement, and multiplication by division, or endogenous formation of cells, is always a sign of lowered vitality; for the more rapid the rate of nutrition and reproduction, the less the stability; *and so* inflammation must of itself always be a destructive process." *Q. E. D.*

The symptoms of inflammation are next given (*functio læsa* being entirely omitted) and explained before we have heard a word about what inflammation is. We now learn, however, that some of the redness is due in certain diseases to hæmoglobin passing out of the vessels *in a state of solution*, causing, for example, the brick-bat colour of lymph in syphilitic iritis. Increased production of heat in foci of inflammation is spoken of as indisputable and undisputed. Turning now to the process of inflammation, we find that there is no new anatomical factor in it, for inflammation is an exaggeration of the normal physiological forces, such as variations in calibre of healthy vessels, exudation of fluids, and migration of white corpuscles, which are described as wandering "habitually to and fro from their vascular abodes." *Contraction* is always the first sign of irritation, is rapidly followed by dilatation, and then stasis gradually sets in. Beyond this nothing is said of changes in velocity of stream, and what "stasis" may mean the student is left to imagine. The quantity of blood delivered by the veins from an inflamed part in different stages of the process, and the variations in blood pressure in inflamed parts are entirely passed over. The explanation given of the mode of production of stasis is most unsatisfactory, the evidence of change in the vessel wall, which Lister brought forward in 1859 as the essential lesion of inflammation, and which Cohnheim has since amplified and christened the "molecular change," not being honoured with a word.

As to exudation of corpuscles, leucocytes are described as clinging to vessels generally, and as passing out through capillaries only. Arnold's stoma-hypothesis, is left on an equal with the theory of molecular change. The corpuscles accumulate in clumps round the connective tissue corpuscles, because these *attract* them. Cartilage-cells are said to multiply in inflammation, but the behaviour of ordinary connective tissue corpuscles is simply left in doubt. The belief which is now gaining ground that the share taken by connective tissue corpuscles varies inversely as the intensity of the process is not hinted at; nor have we come across any mention of those regeneration processes in connective tissue corpuscles, which Sanftleben described, and which have probably caused much of the confusion existing as to the share taken by the tissues in inflammation. The assertion that the fluid exudation contains a quantity of mucin escaped from the blood, or derived from mucoid degeneration of cell protoplasm, strikes us as very doubtful, and we must certainly protest against the discharges from inflamed mucous membranes being used as the most prominent example. Finally, the forms of cells found in the exudation of *acute* inflammation are mentioned, giant-cells being, for all that is stated to the contrary, as common in them as are leucocytes. No explanation is attempted of the mode of origin of the larger forms, but it is thought possible that when formed, they produce small cells by gemmation and fission. Of the modes of termination of inflammation, the description of *organisation* might, we think, be considerably improved. To our great surprise, nothing whatever is said as to the ætiology of inflammation. If pathology teaches at all, surely it is here; and we sincerely hope that no work which omits the subject will be regarded as entirely "suited to the requirements of students preparing for the final examinations."

Farther on, the ætiology of infective inflammation necessarily arises, and here again the information seems behind the time. On p. 43, we find that "infective matter means merely the outcome of the chemical changes that take place in all cases of inflammation;" and again, p. 156, "without doubt tubercle arises from infection, that is to say, it is the product of irritation of the tissues,"—statements ill-calculated to give students a clear idea of infective disease. The bacillus tuberculosis is mentioned, but we can scarcely think that the author had read even an abstract of Koch's paper. In erysipelas, again, could Mr. Pepper find nothing more recent than Lukomsky's paper on cocci in the lymphatics? Surely the work of Orth, and Koch, and Tillmanus, was worth mentioning; and we should have thought that Fehleisen's "Ætiologie des Erysipels," published early in 1883, might have been utilized.

Space will not permit us to go on to other subjects which we might criticise. It will be obvious that a book so faulty in such fundamental matters as the above, can hardly lay a scientific basis for the study of surgery. The results of the faults crop up again and again. Much of the book, however, as we said at the commencement, is written from a clinical standpoint, and is really good. The faults which we have alluded to are grave, and remediable only by re-writing some parts, and carefully revising the whole work. We hope that in the next edition we may be able to congratulate the author upon having carried out the changes suggested.

A System of Human Anatomy; by HARRISON ALLEN. Section IV., Arteries, Veins, and Lymphatics. Section V., Nervous System. London: Henry Kimpton.—The present volumes are a part of a series, the first three volumes of which we had occasion to notice last autumn. The good opinion we then formed of the work is borne out by the parts now in our hands. The author adheres to a systematic plan in his descriptions in a manner to be highly commended. After some general remarks on the blood vessels, the heart is described in detail, a brief account of

its development and of the most common malformations being added. Each artery is next dealt with seriatim, the general direction of each of the branches it gives off, and its final distribution, where it does not divide into named branches, being given. The relations of the artery to the various important structures in its course are then given, as also the chief variations which have been met with, and in many cases the steps necessary in the operation for tying the artery in the several parts of its course are described. In speaking of the veins, the author does not offer any opinion as to function of the valves. This is to be regretted, as it is of great importance, in teaching, to instruct the learner in the use of every organ he meets with, and as the valves constitute one of the chief characteristics of the veins, their purpose ought to have found some mention. The fifth section is devoted to the nervous system. In speaking of the minute anatomy of the cortex of the brain, Dr. Allen contents himself with describing five layers, without any attempt to differentiate between the different appearances seen in different parts of the cortex. In a work claiming to be as exhaustive as this, the omission appears to us to be an important one. In reference to the cranial nerves, no mention is made of the relation between the third and sixth nerves as regards the associated movements of the external and internal recti. Although, perhaps, we can as yet hardly consider it proved beyond all question that a filament passes to the nucleus of the sixth nerve from the opposite third nerve nucleus, yet enough has been written to show that such is probably the fact, and to warrant the mention of the point in a work on anatomy. In preparing this work, the author has evidently not spared his labour, as the copious references to the medical periodical literature of this country alone amply testifies. The plates, though apt to be a little diagrammatic, are good, and the printing and paper are excellent.

Notes on Dental Practice; by HENRY C. QUINBY. London: J. and A. Churchill.—The present volume is just one of those books that puzzle the reader to know why they are written. It does not contain any scientific investigations connected with dental surgery, for the author himself explains in the first few lines of his preface, "it has not been my purpose to attempt to wade in the deep waters of physiological and pathological research." It cannot be regarded as a text-book, or one that could be recommended to students previous to going up for their examinations, for the author puts forward so many theories and points of practice, which are not altogether recognised by the profession at large, that it would decidedly embarrass the mind of any student. We do not in any way wish to deprecate these ideas, as far as the author is concerned, for he is quite at liberty to expound any theories he likes, but for these reasons the volume is disqualified as a students' manual. Again, it cannot be regarded as a work for the general public, for although there are several pages, or even a chapter or two, that the ordinary reader might understand, we frequently meet with rapid transitions into technical language, which would render it unintelligible to the non-professional reader. Neither is it of any actual value to the experienced operator, whose bookshelves are already overcrowded with this class of literature. An elaborate review of the work would be out of place in these pages, but we may mention one or two ideas that do not coincide with generally received opinions. For instance, in the first chapter, the author says, in writing about the premature extraction of the temporary teeth, "In the course of an extensive practice for more than a quarter of a century, I have never met with a case where I considered it necessary." There is no need to doubt the veracity of this statement, but it looks as if the author had never met with a case of extensive alveolar abscess, or a severe case of ulcerative stomatitis, or even a case of actual violence, in any of which cases the temporary teeth may be rendered so loose, and cause such an amount of irritation, that it is absolutely necessary to remove them, whether the permanent successors are due or not. What we complain of is the assertion made to the reader, that although plenty of temporary teeth are annually removed prematurely by other practitioners, during a period of a quarter of a century the author has not considered it necessary to remove one. In his remarks on anæsthetics, the author seems to prefer chloroform or ether, or a combination of them, with a certain proportion of alcohol, to nitrous oxide gas; his principal reasons for his preference being, firstly, that, "the apparatus required for the gas, even in its compressed form, is too bulky for the surgeon to carry about with him;" and, secondly, "that the gas differs from other anæsthetics, in that the return to consciousness is not gradual, but sudden." We are afraid we cannot even agree with the author here, as firstly, several of our well-known anæsthetists have been for years in the habit of carrying their apparatus to administer the gas to all parts without any trouble; and as regards the second quotation, that is not our experience; that persons do return to consciousness quickly we will allow, but not that it occurs suddenly. Space will not permit us to make any further remarks, although there are still several points that we cannot in any way agree with. But enough has been said to show that the book cannot be regarded as a valuable addition to professional literature.

The Descriptive and Surgical Anatomy of the Inguinal and Femoral Regions, considered in relation to Hernia; by EDWARD L'E. LEDWICH, Lecturer on Anatomy in the Ledwich School of Medicine, Dublin. London: Baillière, Tindall, and Co.; Dublin: Fannin and Co., 1884; pp. 99.—This book cannot fail to be of use to senior students, who, having already acquired some knowledge of the anatomy of hernia, by dissection and by perusal of the larger text-books, are desirous of consolidating the knowledge they have so obtained. The author has performed his task so aptly, that any one who will carefully read his treatise, will be rewarded by finding that he has obtained a clear conception of the anatomy of the regions the author has set himself to describe, and, consequently, a thorough understanding of the *rationale* of the various methods of treatment which are adopted for the relief, or cure of the herniæ, that occur within them. We cannot agree with the statement (pp. 18, 65) that it is the custom to describe Poupart's ligament as "a separate and distinct ligament"; and we think the author would have acted more wisely, had he adopted the course usually followed by teachers of anatomy in this country, and described Poupart's ligament as the thickened lower margin of the aponeurosis of the external oblique muscle. The multiplication of the borders and surfaces of this ligament (p. 19) tends to complicate the anatomy of a part which already presents sufficient difficulties to the general student. With the exception of this portion, which we trust may be altered in a future edition, the work is clear, concise, and correct. The plates, which have been most carefully executed, add an additional value to the book.

ABSTRACTS AND EXTRACTS.

RESEARCHES ON THE MICRO-ORGANISMS OF DIPHTHERIA.[1]

By Dr. FRIEDRICH LOEFFLER.

ALTHOUGH nearly sixty years have passed away since Bretonneau published his classical treatise on diphtheria, and notwithstanding the efforts of the long series of workers who have followed in his footsteps, the true ætiology of diphtheria has never yet been established upon a really satisfactory footing. The varied circumstances under which the disease has been observed have led to a variety of views upon the subject. Perhaps in one point only is there any complete agreement, and that is, its infectiveness. The analogy of other infective diseases, in which a

[1] "Reports of the Imperial Board of Health in Germany." Edited by Dr. STRUCK. Vol ii, 1884.

definite micro-organism has been discovered, naturally points to the probability of a similar discovery in diphtheria, and the researches of many observers have been concentrated directly upon this one point in the ætiology.

Dr. Loeffler prefaces the account of his own experiments by a concise summary of the work done by his predecessors in the same field. One of the most important observations which has of late years aided the elucidation of the problem, was published by Dr. Heubner during 1883. Following the line of experiment opened up by Oertel, Weigert and others, Heubner succeeded in producing false membranes upon mucous surfaces by means of mechanically modifying the circulation in the blood-vessels supplying the part. He then injected portions of true diphtheritic membrane into the general circulation, and found that some form of poison became concentrated in these artificially produced membranes, rendering them capable of re-infecting healthy animals with a genuine diphtheria. The general outcome of his work appeared to be, that the local affection was most probably the starting-point of the disease and the seat of the development of the poison. Arguing by analogy, therefore, it must be assumed (1) that certain typical organisms must be present in the affected spots; (2) that these organisms must be capable of isolation and re-cultivation; and (3) that the disease must be reproducible from these cultivations. Heubner, however, failed to prove the constant presence of any definite micro-organism, other than the very numerous micrococci which, according to his theory, ought to be found within the blood-vessels leading to the affected spots. Klebs, on the contrary, found a definite bacillus somewhat smaller than that of tubercle in the upper layers of the diphtheritic membrane in all the cases which he examined.

Dr. Loeffler's own experience is given in detail, particulars of each individual experiment being recorded. The method of staining which he employed consisted in placing the sections for a few minutes in a solution, made by adding 30 ccm of a concentrated alcoholic solution of methyl blue to 100 ccm of Koch's solution of potash (1 to 10,000 parts of water). The sections were then washed with a weak solution of acetic acid and mounted in balsam. All forms of bacteria were found to take this staining-fluid, but the tubercle bacillus showed the least susceptibility, a fact of some importance in distinguishing it from the diphtheria bacillus described by Klebs. The exact conditions found in 27 cases are carefully recorded. Some sections of tonsils showed, after staining, a broad colourless zone on their buccal surface, edged with an irregular blue border, blue spots and streaks extending into it in places. Inside this zone was a layer of numerous violet-stained granule cells, and within that again, appeared a series of irregular processes extending into the muscular tissue, and in places surrounded by a narrow colourless band. Seen by a higher power, the coloured outer layer was found to consist of countless bacteria, micrococci and bacilli; the blue spots being formed by collections of bacteria, with dense masses of micrococci forming long chains. The blue irregular processes were formed of wavy bacilli, the most internal and colourless layer consisted of necrosed tissue, probably due to the action of the long chains of micrococci.

Summing up the results of his observations, the author states his conviction that the whole process is one of necrosis, due to the ingrowth of these micrococci, and that the presence of so many other forms of micro-organisms is simply due to the fact that the decomposing tissue forms an excellent soil for the development of any kind of organism that may find its way into the air passages.

Two distinct varieties, however, are undoubtedly to be associated with the diphtheritic process, viz.—the chains of micrococci and the single bacillus first observed by Klebs. The former of these were always found in the cases where a distinct loss of substance had taken place, not only on the surface, but also pushing their way into the tissues beneath, and so to the lymph glands and the internal organs. It is to be observed, however, that certain micro-organisms which cannot be distinguished morphologically from these have been described by Koch as occurring in the organs in variola, and in typhoid and puerperal fevers. Klebs' bacillus was found exclusively in those cases in which a thick false membrane was present over greatly engorged blood-vessels. The bacilli lay directly under the outer layer of this membrane, irregularly scattered among numberless other bacterial forms. This outer layer was especially rich in cellular elements, and was probably the first result of the irritative effects of the bacilli upon the blood-vessels, the false membrane thus formed being slowly lifted up by the subsequent serous effusion from the vessels. In one case only were these bacilli found in the lungs. They were never found in the internal organs in cases examined shortly after death. In some very typical cases of diphtheria, however, they were not found at all, and hence from the anatomical standpoint alone they cannot be regarded as absolutely specific.

Having thus established the fact that these two varieties are commonly associated with the local changes in diphtheria, Dr. Loeffler proceeded to verify and expand his observations by means of cultivation and infection of animals. The methods employed and the results obtained are described in detail. With the cultivated specimens of the chain-forming micrococcus, the results of infection were for the most part negative, and the author arrived at the conclusion that their presence must be regarded as only an occasional accompaniment of the disease, and not as an active element in its production. With cultivations of the bacillus, however, the results were more decided. By successive cultivations he effectually isolated them and obtained them, free from other bacteria, in a fluid, consisting of a mixture of three-parts of calf or sheeps' blood-serum, and one part of neutralised veal-broth, to which was added 1 per cent. of peptone, 1 per cent. of grape sugar, and one half per cent. of common salt. The bacilli were motionless, staining rapidly and deeply in methyl blue. Some were straight and others slightly bent, their average length being about equal to that of the tubercle bacillus, though somewhat wider transversely. A dark, deeply-stained spot at one end of the rod was observed by Klebs, and thought to represent a spore. Dr. Loeffler, however, who also observed it, failed to find any sufficient evidence of this. The results obtained by infection experiments were remarkable. Although mice and rats appeared to be unaffected by the bacilli, he found that guinea-pigs were very powerfully attacked; distinct false membranes were, in many cases, formed about the seat of puncture, profound disturbance of the internal organs being induced by the poison. Inflammatory œdema of the subcutaneous tissue, local hæmorrhage and general serous effusion were found in the majority of cases. No bacilli, however, could be detected in any other parts than the immediate seat of inoculation. These experiments place the fact beyond doubt that the fatal affection of the internal organs is due, not to the local action of the bacilli circulating within them, but to the influence of some poison, probably set up by the bacilli at the primary point of infection.

Upon rabbits the effects of inoculation, although present, were less marked. In pigeons, a very distinct membrane was produced about the seat of puncture, whether in the breast or in the trachea itself. The bacilli introduced through the mouth into the unwounded larynx produced no effect whatever. Similar results were obtained with like experiments on fowls. Some curious phenomena were observed in the cases of two pigeons and one fowl, in which an apparent diphtheritic paralysis had been induced. In two cases there were found abundant deposits of uric acid (which, by the action of methyl blue, were stained a bright red), and these had evidently set up an arthritis of several joints, whilst in the third, a myxomatous tumour was found pressing on the spinal cord. Dr. Loeffler's paper is concluded by some observations upon diphtheria in pigeons and in calves. The main practical point which comes to the front as the result of his investigations is this, that the diphtheritic process is essentially local in its early stages, and that the poison which exercises its disastrous influence upon the body generally, is developed at the original seat of attack. Hence the paramount necessity of isolation and of disinfection of all discharges from the air passages. The treatment which this view of the disease indicates must, therefore, be mainly directed towards the removal or neutralisation of the infective materials, or that portion of mucous membrane which may be in the first instance attacked.

MEDICINE.

Some recent Researches on Micro-Organisms.—The occurrence of micro-organisms in the living tissues of animal bodies has lately been made the subject of investigation by Dr. Hauser, of Erlangen. He records (*Centralblatt für die Med. Wissenschaften*, No. 21) the results hitherto obtained, although his observations are not yet fully concluded. By separating small slices of various organs from freshly-killed animals, and keeping them free from any possible external contamination, he found that in 72 per cent. of his cases, even after three weeks' "cultivation" in a warm and moist air, no kind of micro-organism whatever had become developed. In a few instances bacteria appeared, but these were attributed to accidental defects in the method of isolation. The influence of various gases upon the development and growth of micro-organisms was also investigated. Their influence was alike negative where no bacteria were present, but in other cases it appeared that the growth was distinctly hindered by carbonic acid gas, and as distinctly favoured by oxygen.

The question of bacterial influence in the origin of pyæmia is once more opened up by a paper by Dr. A. Beltzow (*Centralblatt für die Med. Wissenschaften*, No. 22). Of previous investigators, Koch believed that he had successfully proved that certain micrococci were active in the causation of the disease; whilst Billroth, Frisch, and others maintained that their occurrence in the tissues was only a part of the *post-mortem* phenomena. The author's own investigations resulted in the discovery of a considerable number of bacilli, which appeared in two forms, in addition to numerous colonies of micrococci. Of these two bacillus-forms, the one bore a close resemblance to that which has been found in cases of malignant œdema; and the second appeared to rank, in point of size, between the bacillus of tubercle and that of the septicæmia as observed in mice. Another form, resembling leptothrix bacillus, was found in one instance growing between the hepatic cells, and setting up thrombosis in the capillary vessels.

Professor Baumgarten, of Königsberg, extols the value of the aqueous chamber of the rabbit's eye as a suitable cultivation ground for the tubercle bacillus. (*Centralblatt für die Med. Wissenschaften*, No. 22). Portions of tubercle placed within it do not set up any coarse inflammatory lesion, but a distinct enlargement of the material injected is seen to take place during the next few days. This increase of size is shown by the microscope to be due to multiplication of the bacilli and not to any growth of the tubercular tissue itself. Successive reinoculations of the material so obtained gradually result in the production of bacilli alone, without a trace of other micro-organisms and without any sign of the tissue from which they were obtained. The anterior chamber of the eye, says Professor Baumgarten, fulfils all the requirements of an incubator, supplying the needful temperature, maintaining complete antisepsis and checking the development of any decomposition bacteria.

Cases of Laryngeal Stenosis.—In the "Hospitals Tidende" of March 26th, two interesting cases of stenosis of the larynx are reported by Dr. E. Schmiegelow, of Copenhagen. In one, the patient a woman, aged 26, had suffered from chronic laryngitis ever since an attack of scarlet fever, which had occurred in her fourth year. She had been afflicted with scrofula in childhood, but there was no history of syphilis, nor could the slightest objective evidence of it be detected. Seven years after she came under observation she had been seized with erysipelas of the face; this was followed by dysphagia, and at a later period by loss of voice and difficulty of breathing of such intensity that tracheotomy had to be performed. Since that time the patient had been fairly comfortable, but had never been able to dispense with the tube. When seen by Dr. Schmiegelow (more than six years after the operation), the uvula, pillars of the fauces and posterior wall of the pharynx were found to be thickened and indurated, the mucous membrane being pale and somewhat fibrous in appearance. Laryngoscopic examination revealed a like condition of the epiglottis, aryepiglottic folds and ventricular bands, the vocal cords being entirely hidden by the latter. The mucous lining of the trachea was seen through the wound to present a similar fibrous hypertrophy. No trace of ulceration, present or past, could be discovered. The cause of the stenosis in this instance was no doubt simple inflammatory thickening of the tissues at the upper part of the windpipe. The starting-point of the disease had been scarlatina occurring in a subject of well-marked scrofulous constitution, and the mischief had been consummated afterwards by erysipelas attacking a part which was the seat of long standing chronic inflammation. Dr. Schmiegelow refers to a case reported by (Türck "Klinik. d. Krankh des Kehlk." 1880, Fall 23), as being the only analogous instance he has been able to find in medical literature. The other case occurred in a boy, aged 11, who was suffering from typhoid fever. At the beginning of the fourth week of the illness urgent dyspnœa came on and tracheotomy had to be done. It was afterwards found necessary to leave the tube permanently *in situ*. On laryngoscopic examination about two months after the operation the upper part of the larynx and the vocal cords were seen to be in a perfectly normal condition. Below the glottis, however, two dense-looking swellings, covered with reddish mucous membrane, could be seen, one projecting from each side of the larynx and meeting the other in the middle line, thus completely blocking up the air passage. Dr. Schmiegelow observes that as no *post-mortem* examination of such a case has been recorded, it is impossible to say whether the swelling is due to simple hypertrophy of the submucous tissue, or to perichondritis of the cricoid cartilage. In any case the treatment must be directed to curing the stricture by gradual dilatation with bougies, or with Schrötter's specially devised instruments. We may remark that Dr. Mackenzie states ("Diseases of the Throat and Nose." Vol. I., p. 294.) that he has examined three such cases after death, and in each of them there was disease of the cricoid cartilage. Looking also to the frequency with which perichondritis in this situation occurs in the course of typhoid fever, we have little doubt that Dr. Schmiegelow's case was an example of that complication.

Displacement of the Transverse Colon.—Dr. C. H. Thomas reports the histories and *post-mortem* appearances of three cases of downward displacement of the transverse colon, occurring in sane patients. 1. A male, aged 80, the chief symptoms noted during life were emaciation, anorexia, &c., and a profuse but fitful diarrhœa, alternating with the appearance of a firm tumour 5″ × 2″, lying transversely midway between umbilicus and pubes. The transverse colon was found to be greatly elongated, and depressed in a U-shaped loop. 2. A lady, aged 54, suffered from dragging pain referred to the hepatic region, aggravated by walking, and relieved by prolonged rest in the recumbent posture; obstinate constipation, with indications of obstruction, the capacity of the rectum for enemata being limited to two ounces; and the occasional appearance of two elongated, solid tumours of doughy consistence, one on either side of the abdomen, extending vertically from the border of the ribs nearly to the pelvic rim; they were supposed to be the ascending and descending colon respectively, in a state of fæcal impaction. The transverse colon was found narrowed, elongated, and completely prolapsed, the middle of the U being carried beneath the pubes and lying on the bladder deep in the pelvic cavity. 3. A male, aged 30, the subject of advanced renal disease, suffered from great abdominal pain to the right of, and slightly above the umbilicus: no local enlargement or induration was made out, but this region was intensely tympanitic to light percussion, and misplacement of the large bowel was diagnosed. The necropsy revealed a sharp flexure of the middle of the transverse colon, the apex of the V lying to the right and at the level of the umbilicus. Dr. E. T. Williams directs attention to similar cases mentioned in Bright on "Abdominal Tumours," and in Esquirol's "Maladies Mentales."—*Boston Medical and Surgical Journal*, January 3rd, 1884.

Localised Sweating in Locomotor-Ataxy.—Many phenomena pointing to an affection of the sympathetic

nervous system in locomotor-ataxy have been recorded. Amongst them are: the altered conditions of the pupils, the gastric, intestinal and vesical crises, the permanent acceleration of the pulse which has sometimes been observed, the alterations in the secretions of the alimentary canal, the cutaneous ecchymoses and eruptions, and, according to some, the affections of the nails and joints. To these we must now add alterations in the functions of the sweat glands. In the *Revue de Médicine* for May, M.M. Raymond and Artaud describe the case of a man, aged 46, who was the subject of ataxy, and who presented a well-marked sweating confined to the right side of his face after each meal. This came on in from ten minutes to a quarter of an hour after the meal, and was not associated with any change in the pupil; the sweating occupied the corresponding side of the head and neck, extending to the shoulder. There was no affection of smell or taste, but the patient said that there was increased flow of saliva on the affected side during the sweating. The injection of pilocarpine did not seem to cause more sweating on one side of the face than the other. The authors mention that they have already recorded two cases in which the sympathetic ganglia were found to be affected *post-mortem*, and they allude to Pierret's view that the central origin of the sympathetic lies in the posterior vesicular columns and tractus intermedio-lateralis of Clarke, a region which is very commonly found to be sclerosed in cases of locomotor-ataxy.

The Treatment of the Insane in American Institutions.—The *Boston Medical and Surgical Journal*, December 20th, 1883, contains a summary of a remarkable report on the treatment of the insane in poor-houses and county asylums, presented at the annual meeting of the State Charities Aid Association. It exhibits "a very unsatisfactory condition of affairs from a moral as well as a hygienic point of view." . . . "Insane patients, who might perhaps be cured or improved by proper care in State hospitals, were found cooped up in close cells like ox-stalls." Men and women, sick and well, sane and insane, were herded together like cattle; as a general rule, the insane in country poor-houses were kept in attics, basements, and out-buildings, which were filthy and squalid. In one instance, the insane patients were found shoeless and bare-headed, compelled to sit on the floor, and all—both men and women—under charge of a male pauper. Elsewhere the bath-room "was found in the coal-cellar, and six patients were required to bathe in the same water, which was then saved to wash clothes in the laundry." After such revelations there is a certain *naïveté* in the statement that "these various local institutions seem calculated rather for the encouragement of insanity and misery, than for their suppression."

Exophthalmic Goitre.—In the *Ophthalmic Review* for June, Dr. James Russell contributes a case of Graves' disease presenting some features of interest. The patient was a girl aged 16 years, who presented decided exophthalmos on the left side only. The lids of the right eye were retracted, producing the well-known staring appearance. In the neck there was a very small goitre alike on the two sides. The mother said that at first the two eyes were equally prominent, and that after a time the right eye went down; though it did not regain its natural appearance, the goitre had varied but very little since it was first noticed. The patient was said to have suffered from palpitation, but made no complaint of this whilst under observation. The pulse was repeatedly examined, and was seldom above 100, it was generally under 90, and several times was less than 80. In a note appended after the paper was written, Dr. Russell states that on subsequent examinations of the pulse the average frequency of the beats had been much greater, being above 110 on a majority of occasions of examination. With this there had recurred a certain amount of exophthalmos of the right eye, though not to the same degree as in the other eye. This case seems to confirm a suggestion made by Dr. Fitzgerald in the same journal, that when the cardiac symptoms are absent the other symptoms should preponderate on the left side.

Sudden Death from Pressure on an Inflamed Vagus Nerve.—The *New York Medical Journal*, March 15th, reports the case of a female child, aged 3 years, who was brought to the dispensary on account of a slight cough. Physical examination gave only negative results; the child appeared large and well-nourished, but a peculiar sound was noted to attend the breathing — most marked on inspiration. The patient seemed to get better of the slight cough: at no time was there pyrexia, dysphagia, or dyspnœa. At the end of a month, during a sudden paroxysm of coughing, she was seized with intense dyspnœa, became rapidly cyanosed, and died. The autopsy revealed miliary tubercles scattered throughout the lungs and trachea. The first and second dorsal vertebræ were deeply carious; and in front of them, and behind the œsophagus, was a large abscess. Just below, and to the right of this abscess, was an enlarged, firm, caseous, bronchial gland. The right pneumogastric nerve passed between this enlarged gland and the abscess-sac, and was compressed by them at the point whence the cardiac plexus of nerves was given off. Immediately above this point the vagus was swollen and fusiform, and was found on microscopical examination to be in a state of chronic interstitial neuritis. During the last paroxysm of violent coughing, the continuous pressure on the nerve must have been intensified, probably by a kind of pounding motion, which was sufficient at last to produce cardiac paralysis. No previous slowing of the pulse, such as might have resulted from vagal irritation, seems to have been noticed during the history of the case.

Clinical Aspects of Cerebral Syphilis.—Under this title Professor Horatio Wood publishes in the *Philadelphia Medical Times*, for March 8th and 22nd, an elaborate review of the present state of our knowledge of this affection, in which its ætiological relations are ably set forth. A general conclusion which he arrives at is, "I may state that it must be considered as at present proved that syphilis may produce a disorder, whence symptoms and lesions do not differ from those of general paralysis; that true general paralysis is very frequent in the syphilitic; that the only perceptible difference is one of curability; that the curable sclerosis may change into, or be followed by, the incurable form of the disease. Whether, under these circumstances, it is philosophic to consider the so-called pseudo-general paralysis and general paralysis as essentially distinct affections, each physician can well judge for himself."

The Microbe of Erysipelas.—In a lecture recently delivered at the Charité by Professor Hardy, he observed that the contagiousness of erysipelas had been proved by the existence of microbes, demonstrated by Professor Bouchard. These were abundantly exhibited in the serosity of the phlyctenulæ in the cases now under consideration. These microbes bear a strong resemblance to those of puerperal fever, being of a very regular spherical figure, and existing sometimes in an isolated condition, but at others attached to each other in a plane surface, or arranged as chaplets or columns. In some instances they were surrounded by an envelope, which, becoming ruptured, left the microbe free. —*Gazette des Hôpitaux*, April 3.

REPORTS OF SOCIETIES.

HARVEIAN SOCIETY OF LONDON.

Thursday, May 15th, 1884.

G. P. Field, M.R.C.S., President, in the Chair.

Hypospadias.

Mr. Edmund Owen showed a coloured drawing of a subject of Hypospadias in which the sex had been originally mistaken. The child had been named Florence Kate, but when Mr. Owen saw it, at the age of 16 months, he discovered the testes near the crest of the pubes and

suggested that the name be changed. The boy was therefore re-registered by the name of Sydney. He was now four years old and was in every other respect well developed. If there were a doubt at any time about the determination of the sex of a child, it was much more likely to be an imperfectly developed boy than a girl.

Adjourned Debate on Scarlet Fever.

Mr. Cripps Lawrence, referring to the report of his opening remarks (on April 3rd), which had appeared in the Medical Journals, stated that the expression "imperfect volatility" should have been used instead of "volatility" in connection with the poison of scarlet fever, in accordance with the drift of his observations on that subject.

Dr. Cheadle, in re-opening the debate, laid stress upon the specific nature of the virus. Its elaboration required a longer time than that of measles; the latter was contagious almost from its earliest manifestation, whereas the former was much less potent prior to the appearance of the rash than during desquamation. Families and individuals differed widely in their liability to the disease. The nature of this susceptibility was a subject well worthy of the attention of the "Collective Investigation Committee." Again, the same persons showed very different vulnerability at different times. This was illustrated by the case of a former house surgeon of the Hospital for Sick Children, who, after having resisted the concentrated infection of a scarlet fever ward, contracted the disease in the midst of the duties of a country practice. *Surgical Scarlet Fever* was probably contracted by contamination of the highly absorbent surface of recent wounds. In strict analogy with what happened in inoculated small-pox the incubation was much shortened and the disease attenuated. Propagation by wound, inoculation, was not hitherto known in the case of measles or enteric fever. The influence of race as an ætiological moment was open to some doubt. The difference in severity observed in scarlet fever in France and in England respectively, was best explained by reference to past history. Formerly, scarlet fever had been very mild in this country; Bretonneau, on the other hand, had recorded a severe outbreak, contrasting with his previous experience of the disease in France. The variations were rather between epidemics than between countries. Climate, however, probably exercised an influence, although this was not necessarily based upon mere degree of temperature. Thus in India the disease, although repeatedly introduced, had never obtained a footing, whilst in Southern Africa it had lately assumed considerable virulence. In diagnosis extreme caution was necessary in cases where a rash coincided with any rise in temperature; and instances were adduced to illustrate the difficulty often experienced in forming an opinion at an early stage of the symptoms.

Dr. Squire had given some attention to the general epidemiology of the subject. Whereas epidemics differed greatly in virulence, race did not constitute a leading factor. That improved sanitation did not exercise any marked control over the march of the disease, its recent aggravation in England furnished clear proof. The immunity of India was due to the comparative isolation of the European element by whom the disease was imported, by the early removal of European children, and above all by the absence of most of the agencies which in this country bring about contagion from person to person. This pointed to the direction in which improvement might be effected. In France, children were systematically inspected before their admission into school; but in England too frequently attendance at school was enforced in the face of sanitary indications. Although the shortened incubation of surgical scarlet fever had been adduced as proof of its inoculation into wounds, this point was far from settled. A case was narrated in which the injury was received and scarlet fever contracted three days after entrance into a new house which could not have supplied any contagion. Hardly enough stress had in the previous discussion been laid upon desquamation as an infecting agent. In respect of treatment, mischief was likely to arise from the indiscriminate use of the warm bath in the premonitory stage. This practice was well calculated to aggravate the pyrexia and to favour the onset of convulsions in children.

Dr. Hopwood had collected twelve good cases in which the duration of exposure had been limited to half-an-hour or an hour, and onset had followed in 68 to 78 hours. Surgical scarlet fever was not a distinct variety. The disease had been contracted under the use of every antiseptic precaution, including the spray, and in cases where the wound had run an aseptic course diagnosis was often difficult. In German measles desquamation was generally limited to the head and neck. In this disease it was possible to distinguish a morbilliform and a scarlatiniform variety. One variety was capable of breeding the other.

Mr. Malcolm Morris deprecated harsh criticisms of the diagnosis of fellow-practitioners. In scarlet fever four prominent indications required consideration:—the rash, the throat, the tongue, and the pyrexia; any of these or several might fail us. The rash was the most important, for in its complete absence diagnosis was at best but a guess. There were two typical varieties of eruption—the hæmorrhagic variety, special to severe cases, and the milder punctate form. Urticaria was often most difficult to diagnose from scarlet fever; but where any doubtful rash existed, isolation was the means to adopt, although the event might falsify our apprehensions. An exterior desquamation was an important guide. Of all the means proposed for checking the diffusion of contagious epidemic scales, constant bathing, as suggested by Dr. Jamieson, in the *Edinburgh Medical Journal*, was the most promising, yet better results might be expected from continuous immersion during two or three days at the height of desquamation. Continuous immersion was practised in Vienna with good results in the case of burns.

Mr. Mason considered the question of the spontaneous development of the disease, and narrated a series of cases occurring in the same house. A child died in four days from the hæmorrhagic form of the fever, the nurse suffered from severe diphtheritic sore throat, and the father acquired severe erysipelas before the dead body had been removed. Although inspection revealed no insanitary condition in the house, decaying vegetable refuse was discovered in the vaults opening into the area. Contagion was capable of clinging for long periods to articles of clothing. In the speaker's experience most of the parturient women infected by the disease were quite free from all abrasion. Diffuse peritonitis had generally ensued, abrupt in its inception, violent in its course. The desquamation stage was best treated by carbolised inunctions and warm baths. A case was adduced in support of the volatility of the contagion.

Dr. Dawson Nesbitt suggested that the mildness of the disease in France might bear some relation to the lighter diet adopted in that country. The question whether practitioners engaged in midwifery should attend scarlet fever was one requiring serious consideration.

Dr. Alderson, after anxious investigation of the subject last mentioned, had arrived at the conclusion that very rarely could puerperal disorders be traced to scarlatina infection. He had repeatedly attended parturient women where scarlet fever was in the house. Two instances were related in which the parturient mother escaped, although children were at the time suffering from the disease, in one case from a severe form. The danger from erysipelas was much more real. In his series of upwards of 1,500 confinements, he had only known one case of real puerperal scarlet fever; on that occasion he had not attended any case of scarlet fever the same day. Isolation of unattacked persons, when enforced prior to exposure to desquamation, could be looked upon as completely successful after the lapse of ten days. In confirmation of this statement two cases were fully detailed.

Mr. Edmund Owen related three cases of surgical scarlet fever. In one case tracheotomy was performed for the removal of a fish-bone; scarlet fever ensued after two days, and the nurse took genuine scarlet fever from the patient. An operation for cleft palate in a boy was followed by elevation of temperature, erythematous rash and albuminuria. Scarlet fever was at that moment prevalent in the hospital. The fact that eight days after the operation the wound was found to have healed from end to end, showed that no asthenic influence was exercised. The third case was one of amputation of the thigh for disease of the knee-

joint. Sore throat and regurgitation of food through the nose led to the suspicion of scarlet fever, although the temperature was normal; and the patient was sent to the Fever Hospital, where the wound progressed most favourably. No desquamation was noticed. Mr. Owen also alluded to the experience of Mr. George May, jun., related in the *British Medical Journal*, for 1879, in which several children acquired scarlet fever from a surgical case of the disease, which Mr. May had, at first, held to be septicæmic, not scarlatinal.

Dr. MEADOWS regretted that the terms "surgical" and "puerperal scarlet fever" had ever been invented. The disease in every case conveys itself and nothing else; whoever attends any considerable number, should not attend pregnant women. As to the mode of infection, an analogy had been drawn between the placental site and an amputation wound. No such analogy existed; and in addition the vagina was closed, and the uterus practically closed. But there did exist a condition of blood, causing susceptibility to the poison. Although little could be said in support of carbolised spray during delivery, vaginal injections and uterine injections were of the greatest value in removing the secretions which most frequently were answerable for puerperal fever. Uterine injections should only be practised according to definite rules, regard to which would preclude the danger of peritonitis *ab injectione*.

Mr. CRIPPS LAWRENCE was glad that the debate he had introduced had been so fruitful in suggestions. He was thankful to have had an opportunity of discussing the "conscience-clause," to which he had always adhered. Time did not allow of a detailed reply to the observations made by the various speakers.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE V.

FOOD.

Tea—Maté—Coffee.

IN this number we commence a series of articles on the food products at the Exhibition, which will differ in some important respects from those appearing in so many weekly and daily journals, more especially in that we accept and reproduce no statement relating to any exhibit without a strict examination, nor do we give any decided opinion save after a chemical and microscopical investigation.

The exhibitions of food products occupy much space, and are pretty well all collected in the South Gallery; their position is therefore such that the first visual impression on entering, and the last visual impression on leaving the Exhibition is necessarily that of the various cases containing alimentary products.

Tea.

Considerable prominence is given to teas cultivated in India. About half a century ago in the virgin forests of Assam, the indigenous Indian tea plant was discovered, and in 1840 the Assam Company was founded, but for several years Indian teas were little known and produced but in small quantities. Their cultivation has, however, been so developed by British capital and British planters, that 240,000 acres of jungle have been cleared in various Indian districts, and the out-turn has grown from a million of pounds in 1864 to 60 millions of pounds in 1883, which is equal to one third of the whole consumption of the United Kingdom. If this process goes on, a time will come when tea will be wholly and entirely supplied from plants grown within the limits of the Empire, a very desirable consummation.

We have specially examined three samples of tea of the Kangra Valley Association.

Nearly all the analyses of tea published, represent not what the people actually drink, but the amount of matter the chemist can extract. This mode of judging of the quality of tea is essentially erroneous. We have, therefore, examined these by imitating as far as possible domestic tea-making. A known weight of tea has been infused in London water, at 212° F.; and after standing the usual time, the water has been poured off, and a little more added, and the same process repeated. The infusion has then been made up to a known bulk, and the tannin, theine, extract and ash therein estimated. Examined in this way, a good idea is formed of what is actually consumed, for the amount of tannin, theine, cellulose and mineral matter left in the tea-pot is of scientific interest only.

1. Kangra Valley tea, Orange Pekoe, price 4*s.* per lb. A one per cent infusion yielded:—

	Grm.
Theine	·029
Tannin	·144
Total extract	·28
Ash	·04

2. Kangra Valley tea, Pekoe, price 3*s.* per lb. A one per cent. infusion yielded:—

	Grm.
Theine	·025
Tannin	·138
Total extract	·28
Ash	·04

Both these samples are high-class teas, but although there is no less than 1*s.* per lb. difference in price, neither analysis nor taste differentiates them in the same degree; the higher priced is a little more astringent and nitrogenous than the lower, but the flavour of the Pekoe was preferred by all the people to whom it was submitted.

3. The third tea, named Pekoe Souchong, price 2*s.* 6*d.*, gave, when examined in the same way:—

	Grm.
Theine	·016
Tannin	·090
Total extract	·22
Ash	·04

It is thus considerably weaker in all constituents extracted by water, but it has an excellent flavour, and is about the best 2*s.* 6*d.* tea the writer has ever examined.

We have also studied two high-priced teas sold under the names of Hands' afternoon tea (4*s.*), and Hands' blended Kaisow (5*s.*), in precisely the same way, with the following results:—

—	Hands' afternoon tea, in 100 c. c. of infusion.	Hands' blended Kaisow, in 100 c. c. of infusion.
	Grm.	Grm.
Theine	·024	·028
Tannin	·082	·054
Total extract	·228	·484
Ash	·056	·084

The last teas ejected, when infused are thus seen to be less astringent than those of the Kangra Valley; the flavour and general qualities are of a high character.

Leaving the Indian teas, Messrs. Goundry and Co. exhibit their patent consolidated tea. By hydraulic pressure a quarter of a pound of tea is reduced to a firm, solid little block which might be carried in the waistcoat pocket. The compressed tea was treated in the same way as the rest, viz., by the method of infusion. It yielded:—

	In 100 c. c. Grm.
Theine	·032
Tannin	·056
Total extract	·256
Ash	·020

The manufacturers affirm that more extract is obtained from tea which is compressed, than the same tea in the natural state; the immense pressure breaking up the parenchyma, and as it were pulverising the tea-leaf. We find this statement to be correct, but the difference in the amount of extract obtainable is so small as not to have much practical value. For convenience of carriage this consolidation of tea will be found most useful. If we mistake not, the pro-

cess in a less perfect degree is as old as the cultivation of the tea-leaf, a very large proportion of Chinese teas having been always exported Overland in the form of what has been called "*brick tea.*"

Guided by the analyses quoted, it may be useful for the physician to know in English grains per ounce the quantity of active constituents in tea infusion, which, with ordinary good tea, we believe will be nearly as follows:—

	Grains per fluid ounce.
Theine	·10
Tannin	·35
Total extract	1·30

It hence follows that twenty ounces of tea will not contain a dose of theine sufficiently large, if given by itself, to produce any evident physiological effect.

Maté.

There are two exhibits of the Maté leaf and twigs, otherwise called "Paraguay tea." Dr. W. Fleming Phillips, has sent a sample, together with the maté cup and the *bombilla* (No. 19), while Messrs. Christy also show a sample in their exhibit of new food products (No. 98). The two samples of maté are practically identical, no difference in quality can be detected; they may, for aught we know, have been derived from the same bundle.

In the Argentine Republic the annual consumption of maté is said to be 27 million pounds. The usual way of making the tea is to pour hot water on the leaf, then add a lump of burnt sugar, and finally a few drops of lemon-juice, but the latter addition is often omitted. The infusion is not drunk from cups, but sucked up through a tube (*bombilla*) which, possessing a perforated bulb or strainer, filters the tea.

An infusion of the little twigs and leaves, made precisely on the lines of the other teas examined, gave the following results:—

In 100 c. c. of Maté infusion (strength 1 per cent.).

	Grm.
Theine	·015
A peculiar tannin	·051
Total extract	·164
Ash	·004

The taste was rather pleasant, and reminded one of ordinary tea; it certainly was more agreeable in every way than some of the cheap Chinese teas, and as it could be imported into this country at a very low rate it might supplant inferior teas if its use could in any way be popularised.

Coffee.

The use of coffee seems to have somewhat declined of late years, the reason without doubt being the unfair treatment the berry has from first to last received. It has been adulterated more than any other substance; it has been mixed with all sorts of things; great companies have been started with the avowed object of manufacturing and selling a substitute for coffee; and, lastly, few people have known how to make an infusion, so as to bring out its virtues. We are, therefore, much pleased to see the efforts made by the coffee planters and merchants to instruct the public in the Exhibition. There are not only model coffee-houses and stalls, but exhibits in which improved methods of roasting and preparing the coffee berry are to be seen in daily operation.

Beare, Gosnell and Co., in the Western Gallery (No. 1,245), show machinery for making and roasting coffee, and also an ingenious machine for roasting small quantities at the breakfast table. They rightly say that the whole secret of making good coffee is to use only the freshly roasted and freshly ground berry.

A sample of their coffee (1*s.* 6*d.* per pound) infused with boiling water so as to equal a 5 per cent. solution, gave the following results:—

	In 100 c. c. of infusion. Grm.
Theine	·032
Caffeo-tannic acid	·160
Total extract	·945
Ash	·180

Since the full flavour of coffee can only be obtained by grinding and infusing the freshly roasted berry, numerous attempts have been made, with more or less success, to concentrate the infusion of good coffee into an essence. We have recently examined an essence of coffee from the exhibit of Mr. Thos. Curr (No. 77), in which a fair amount of success has been obtained. The extract contains

	Per cent.
Water	37·0
Organic extract (ash free) ..	60·1
Ash	2·9
Nitrogen	·49

This extract makes a good cup of coffee, but, as might be expected, a little of the delicate aroma is lost.

GENERAL CORRESPONDENCE.

HYDRO- AND PYO-SALPINX.

[To the Editor of the Medical Times.]

SIR,—Mr. Lawson Tait's letter on the above subject in your issue of May 17th has only just come under my notice. In my remarks at the Obstetrical Society, November 7th, 1883, which Mr. Tait refers to, I did not say cases of hydro- and pyo-salpinx were never found in the *post-mortem* room of Guy's Hospital, but that they were so rare that I myself had never seen a case. In his reply to my remarks, Mr. Tait stated (*vide British Medical Journal*, December 7th, 1883) that "cases of pyo-salpinx were not seen in hospital *post-mortem* rooms, because they commonly died from peritonitis too quickly to come into hospital." It is curious that now in his letter Mr. Tait virtually admits that they do not die too quickly to get into hospital *post-mortem* rooms, but that they are not more frequently met with he explains away by saying they are not properly looked for by the pathologists. Mr. Tait asserted also at the Obstetrical Society that four or five, it might be even eight or ten, of the sixty-five cases he had operated on had been under treatment at Guy's Hospital. With the view of obtaining the medical reports of these cases from the records at Guy's, I wrote to Mr. Tait for the names of the patients he had referred to. I extract the following from his reply, dated November 10th, 1883:—

"But one thing I will not do—and that probably is essential for the fulfilment of your intention—I will not give any clue to the identification of cases. I will give you the history and symptoms recorded, and will let you have the preparations of the tubes removed; but my past experience of permitting this class of cases to be identified has been so unpleasant for the patients that I shall not willingly make such a mistake again."

In a postscript Mr. Tait mentions one case about whom he states identification does not matter. She was a woman with three aliases, and I have not been able to find that she was ever under treatment at Guy's Hospital under any one of the three names given to me by Mr. Tait. What I maintain is that cases of hydro- and pyo-salpinx are not very common, and when they do occur, treatment by rest, local applications, and internal remedies is often sufficient to effect a cure without using the knife. I have just had a case under my own care in Guy's Hospital cured by this plan.

I am, Sir, yours &c.,

P. HORROCKS.

St. Thomas's Street, S.E.
May 26th, 1884.

AN EXPENSIVE PRESCRIPTION.—It is scarcely credible, says the *Allgemeine Wien. Zeit.* (May 6th), but it is quite true, that in Vienna, the "seat of the most renowned faculty in Europe," a young physician has prescribed gold—the inutility of which in the treatment of disease has been acknowledged for the last 200 years—for the relief of an obstinate nervous affection. The prescription for 40 or 50 pills costs 12 florins, so that their prolonged continuance will need the purse of a Rothschild. Thus far the patient finds that they lie very heavy at his stomach, and his health is rather worse than better.

INVENTIONS AND IMPROVEMENTS.

THE OBSTETRIC VADE-MECUM.

Messrs. Coxeter, of Grafton Street East, Tottenham Court Road, have introduced, on the suggestion of Dr. Charles Read, a handy bag for midwifery and cases of abortion, intended especially for the general practitioner. The peculiarity of this new device is that it contains every

appliance required for the conservative treatment of obstetric difficulties, while omitting all those of a destructive nature. The bag does not contain, nor is it intended to contain, the heavy and unwieldy instruments needed for craniotomy, cephalotripsy, and embryulcia, and it is thus possible for it to be eminently portable. We hope that no practitioner is so over-ready with his fœticide appliances, as to use them, when it would be possible to do without them. But it may be pointed out that in town-practice the delay involved in sending for them, in the rare cases in which they are needed, would seldom be prejudicial to the mother, while in country practice the practitioner would probably have them at hand in his trap. As for consulting obstetricians, even Dr. Read, we imagine, would hardly advise them to make his Vade-Mecum their sole companion when called to a case of difficulty. We may say, in conclusion, that we have carefully gone through the contents of the bag, and can suggest no addition; and, indeed, when it is considered that they include everything recommended in Dr. Barnes' "System," any such suggestion might almost seem to savour of impertinence.

PICHARD AND CURRY'S DOUBLE ADJUSTABLE TRIAL FRAME.

(Suggested by Dr. Tosswill, of Exeter).

The principal advantages claimed for this frame are its extreme lightness, and the great facility which it affords for working out cases of astigmatism, whilst the mechanism is of the simplest description. It consists essentially of two flattened graduated rings, behind which are semi-circles for the reception of the spherical lenses. In front of each broad graduated ring is a narrow movable one, to which is attached a steel semi-circle for the reception of the cylindrical lenses. Each movable ring has a small rod-like handle, which projects beyond the graduated ring, and by means of these handles the surgeon can alter the position of the cylindrical lenses to any extent he pleases, without touching the lenses or removing the frame from the patient's face. The position of the cylindrical axes can be read off at any time by means of the graduated rings. Both graduated rings are attached by steel stems to a divided bar, one ring being fixed and the other movable; whilst the nose-piece is made to move both vertically and laterally, so as not only to be adjusted to the exact height of the nose, but also to the exact centre between the two rings. By means of the graduated divided bar, the inter-pupillary space may be accurately determined.

MEDICAL NEWS.

Royal College of Physicians of London.—The following gentlemen were admitted licentiates, on May 29th, 1884:—

Arthur Cecil Deare, 40, Bassein Park Road, W.; William Raoul De Morinni, St. Bartholomew's Hospital, E.C.; Percy Edmund Maitland, 12, Albert Street, N.W.

Royal College of Surgeons of England. — The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners on the 29th ultimo, and when eligible will be admitted to the pass examination for the Fellowship, viz.:—

Messrs. Frederic J. Smith, student of the London Hospital; William Permewan and Paul W. Fraser, of University College Hospital; Albert Careless, of King's College Hospital; John A. Smith, of St. Bartholomew's Hospital; George Rowell and John W. Washbourn, of Guy's Hospital; John Cahill, of St. George's Hospital; and Henry Tonks, of the London Hospital.

Nine candidates having failed to acquit themselves to the satisfaction of the Board of Examiners were referred to their Anatomical and Physiological studies for six months. Ninety candidates presented themselves for the examination just completed, as compared with 86 at the corresponding period last year; of this number 48 were referred for six months' additional studies.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 29th, 1884:—

Charles Joseph Arkle, 18, Portland Terrace, Regent's Park, N.W.; Henry Samuel Cook, Acock's Green, near Birmingham; Andrew Watson Kerr, 29, Prospect Street, Belfast; Charles Patrick Maguire, 1, Compton Street, W.C.; Joseph Hugh McMullan, Belfast; George Samuel Sims, St. Thomas's Hospital; Joseph Eagland Walker, 158, Stanhope Street, N.W.; William Windley, 27, Disraeli Road, Putney.

Royal College of Surgeons in Ireland.—The College of Surgeons held their meeting on the 29th ultimo, pursuant to the provisions of the Supplemental Charter, to elect officers for the ensuing year, when the following gentlemen were elected:—Presidency: Edward Halloran Bennett. Vice-Presidency: Anthony H. Corley. Secretaryship of the College: William Colles. Council: William Colles, Sir George H. Porter, James H. Wharton, William A. Elliott, George H. Kidd, T. Jolliffe Tufnell, Edward Hamilton, Robert M'Donnell, J. Kellock Barton, Edward D. Mapother, Archibald H. Jacob, Philip Crampton Smyly, William Stokes, W. Thornley Stoker, William Stoker, William I. Wheeler, Samuel Chaplin, William Carte, Charles A. Cameron, Henry Fitzgibbon.

University of St. Andrews.—The extension of the museum and the erection of biological laboratories having become urgent, because of the requirements of modern science teaching, the authorities of the University have resolved to approach Government with a view to secure these very desirable objects. There are few situations in any country better adapted on the whole for the combination of a biological station with laboratories than St. Andrews. The proximity of the city to the sea—with the fine stretch of sand on which so many rare specimens are thrown by storms, or gently stranded by ordinary tides—in juxtaposition with the University and its valuable library and museum, afford facilities for zoological research such as are rarely to be met with. More than twenty years ago, Dr. Mackintosh, the present Professor of Natural History, brought this under notice in various lectures. In the beginning of 1875, the subject was again prominently referred to, and amongst others, Dr. Dohrn, of the celebrated zoological station at Naples, cordially concurred. He indeed alluded to the University as, by "its position near the sea, inviting more than any other to the now all-important study of marine zoology." Finally, in March, 1883, an effort was made to obtain a portion of a considerable sum of money handed over by the Committee of the Edinburgh Fisheries Exhibition to the Scottish Meteorological Society, with a view to founding such a station at St. Andrews. The authorities of the University of St.

Andrews believe that this extension would result in great good to science and the public; and they feel assured that their efforts will be warmly supported.

Naval Medical Department.—The following promotions and appointments have been made:—Inspector-General of Hospitals and Fleets J. N. Dick, to Haslar Hospital. Staff-Surgeon H. C. Woods, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet. Fleet Surgeon E. H. Evans has been placed on the Retired List, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets. Fleet Surgeons —G. Mair, M.D., to the *Durham;* Samuel Bamfield, to the *Sultan;* Staff Surgeon—Richard V. McCarthy, to the *Serapis;* Surgeons — Percy W. Bassett-Smith, to the *Triton;* Denis W. Donovan, to the *Monarch;* Hugh W. McNamara, to the *Helicon;* Henry B. Collins, to the *Woodlark.*

Charitable Bequests.—Mr. George William Nugent has left the following legacies:—200*l.* each to the Seamen's Hospital, late the 'Dreadnought,' Greenwich; the London Hospital, Mile End; St. Mark's Hospital for Fistula, City Road; the Royal Free Hospital, Gray's Inn Road; the Free Hospital, Commercial Street, Spitalfields; the Western General Dispensary, Marylebone Road; St. Mary's Hospital, Paddington; the Hospital for Sick Children, Great Ormond Street; the Female Lock Hospital and Asylum, Harrow Road; the Middlesex Hospital, Berners Street; the Hospital of St. John of Jerusalem, Great Ormond Street; and St. Raphael Hospital, Sydney Street, Fulham Road. The late Mr. John Smith, Aberdeen, has bequeathed 200*l.* each to the Royal Infirmary, Convalescent Hospital, and General Dispensary in that city.

The City Coroner.—At a court of Common Council held a few days since, the Officers and Clerks Committee brought up a report relating to the vacant office of City Coroner, recommending that as heretofore the court should appoint one person to be Coroner of the City of London, and the town and borough of Southwark; that it was not expedient to confine the qualifications of candidates either to the legal, medical, or any other profession; that the gentleman appointed should undertake to discharge personally all the duties of the office, except when prevented by illness or other reasonable cause, and that he should be required to provide an office within the City. The total remuneration for both offices was at present 1,055*l.* per annum, but that remuneration was subject to increase or decrease, on revision, by the Justices of the City of London and the county of Surrey respectively, in accordance with the provisions of the statute. The report was agreed to, and the Town Clerk said the Lord Mayor had arranged that the election of the City Coroner should take place at the next meeting of the court on June 12th.

Hospital for Consumption, Brompton.—The annual court of governors was held on May 29th. From the report it appeared that there had been 1,537 in-patients admitted in 1883, compared with 1,033 in 1882. Of 1,763 altogether under treatment, 1,243 had left, many greatly benefited, 209 had died, and 311 remained in the hospital on the 31st of December last; 13,341 new out-patient cases had received advice and medicine in 1883. The receipts had been—Annual subscriptions, 6,840*l.* 17*s.* 6*d.*; donations, 4,336*l.* 6*s.*; Church collections and Hospital Sunday and Saturday Funds, 1,800*l.* 7*s.* 5*d.*; incidental receipts, 971*l.* 7*s.* 11*d.*; legacies, 9,318*l.* 3*s.* 6*d.*; rents, 1,133*l.* 14*s.* 5*d.*; dividends, 1,892*l.* 14*s.* 1*d.*—total, 29,393*l.* 10*s.* 10*d.* Expenditure, 24,882*l.* 6*s.* 1*d.*; do. in respect of new building, 5,404*l.* 8*s.* 10*d.*—total, 30,286*l.* 14*s.* 11*d.* The committee desired to call attention to the financial position of the charity. There were now 331 beds in the two buildings, and to keep these occupied 24,000*l.* a year or more would be needed. Towards this the only fixed income was about 2,850*l.* from rents and dividends, the latter source of income being, however, reduced by every sale of stock from the limited capital, these sales having already become needful on account of the great increase in the expenditure since the opening of the new building. The hospital was, therefore, not rich, as so many supposed it to be; but on the contrary, it was only by means of increased subscriptions and liberal donations, with the help of legacies, that this great work could be carried on, and the necessity for closing some of the wards could be averted.

County Infirmaries in Ireland.—At a meeting of the Statistical and Social Enquiry Society of Ireland, held on Tuesday, May 20th, Dr. Hercules McDonnell, Surgeon to the Dundalk Infirmary, read an interesting paper on the subject of the "County Infirmaries of Ireland." Each county infirmary exists as a separate unit, controlled by its own board of governors, and answerable only to the grand jury of its own county. They were originally established by Act of the Irish Parliament in 1765, to afford medical and surgical relief to the poor. The cases admitted are in all essentials of the same class as those treated in our metropolitan hospitals. Their means of support are mainly derived from presentments levied as county cess. The 27 county hospitals had in 1881 1,580 beds available and in use, giving an average to each of 58½; 12,953 patients were treated as interns, giving an average to each institution of 479. The gross expenditure amounted to 29,264*l.* 18*s.* 9*d.*, or an average cost per patient of 2*l.* 5*s.* 4*d.*, and per bed 19*l.* 10*s.* 5½*d.* The actual cost of the infirmaries to the cess-payer amounts to one halfpenny per 1*l.* of his valuation. For this amount he obtains the advantages of having an hospital replete with every surgical and medical appliance, and maintained in a state of efficiency, which compares most favourably with our metropolitan hospitals. The rooted repugnance which exists to entering a workhouse hospital does not obtain here. No pauperising element enters into the question, nor is anyone disfranchised for accepting such relief.

Experiments on Animals.—At the recent meeting of the American Medical Association, the following resolution, proposed by Dr. Horatio C. Wood, of Philadelphia, was adopted unanimously—"Whereas it appears that an effort is being made to restrict by legislative action the practice of investigation in medical science by experiments on animals; and whereas, in the opinion of this Association, such restriction is not needed for the guidance of medical men in their investigations, and would be an injury and hindrance to the pursuit of knowledge and the improvement of the medical art; it is therefore resolved that a standing committee of seven be appointed by the President of the American Medical Association, to be known as the Committee on Experimental Investigation, charged with the duty of opposing, by all legitimate means, any interference with the progress of medical science by unwise or ill-considered legislation." The Committee appointed consists of Drs. Horatio Wood, W. Pepper, James Tyson, of Philadelphia; Christopher Johnston, of Maryland; J. C. Dalton and Austin Flint, jun., of New York; and J. S. Billings, of the United States Army.

Hospital Saturday and Sunday in New York.—*The New York Medical Journal* reports that "the sum collected for Hospital Saturday and Sunday in 1883 amounted to $43,062.74, or more than $12,000 in excess of the collection of the preceding year, and only $1,000 less than the largest collection ever made, viz., that in 1880, which included a special gift of $5,000. In the light of these facts and of the commercial depression that marked the close of the year, the time when the collection was made, the Association seems abundantly justified in regarding the result of its labours for the year as decidedly encouraging. But it is not only in the matter of the gross sum collected that an inference is to be drawn implying that the people of New York are not flagging in true interest. Looking over the list of sources from which the contributions were derived, we notice a great many that have never figured before. On the other hand, it is quite rare to find a blank opposite the name of any former contributing organisation. The Association may also derive satisfaction from the small proportion of 'designated' contributions, being those accompanied by a specification on the part of the contributor of the hospital to which he prefers his gift to go. This indicates a degree of confidence in the Association's plan of dividing the money that could not be felt except for good reasons."

NON-RESTRAINT IN AMERICAN ASYLUMS.—When we recollect the opposition so long offered to the introduction of the non-restraint system into the asylums of the United States, it is very gratifying to learn that this is soon likely to be a thing of the past. The *New York Medical Record* of May 17th, after alluding to the adoption of the system by asylum after asylum, observes, "The charge has been made that those who have given up mechanical restraint have supplied its place with drugs; but this charge is refuted by the elaborate investigation of the late Dr. Wildbur, who showed that in the asylums, both in Great Britain and the United States, with non-restraint a less amount of sedative drugs was used. In fine, the opinions of American asylum superintendents upon the subjects of non-restraint and occupation have undergone a surprising change in the last five years."

ABDOMINAL SURGERY.—At the meeting of the Canada Medical Association in Montreal, an address in Abdominal Surgery will be given by Mr. Lawson Tait.

AT the last meeting of the Court of Common Council, the Lord Mayor presiding, two hundred guineas were voted in aid of the funds of the Royal Free Hospital.

APPOINTMENTS.

ACLAND, T. D., M.B.—Assistant Physician to the Hospital for Consumption and Diseases of the Chest, *vice* D. King, M.B., resigned.

BARLING, G., M.B.—Honorary Assistant Surgeon to the Birmingham and Midland Counties Orthopædic and Spinal Hospital, *vice* E. L. Freer, M.R.C.S., resigned.

CATHCART, W., M.B., F.R.C.S.E., Assistant Physician to Edinburgh Royal Infirmary.

GRANT, H. L., M.B.—Assistant Medical Officer to the Buckingham County Asylum, Stone, near Aylesbury.

JEFFERISS, WALTER ROBERT SPENCE, L.R.C.P. and L.R.C.S. Edin., M.B. Univ. Edin.—Medical Officer to the Second District, Alston-with-Garrigill parish, *vice* Dr. Alfred Pickworth, resigned.

JESSOP, C. M., M.R.C.P.—Physician to the St. Pancras and Northern Dispensary.

LOVERIDGE, A. W., M.R.C.S.—House Surgeon and Secretary to the West Norfolk and Lynn Hospital, *vice* S. H. Lindeman, M.R.C.S., resigned.

MACAULAY, SAMUEL, M.D. and M.C.Q.U. Ire., L.M.K. & Q.C. Ire., L.S.A. Lond.—Medical Officer to the Sixth District, Maidstone Union, *vice* Mr. J. W. Bury, resigned.

MCCULLOCH, ALLEN, M.B. and M.C. Glas.—Medical Officer to the Tarporley District, Nantwich Union, *vice* Dr. Potts, resigned.

MURRAY-ROBERTSON, T., M.B., M. Ch. Edin.—House Surgeon to the Durham County Hospital, *vice* C. H. Milburn, M.B., C.M., resigned.

ORWIN, ARTHUR, W., M.D.—Surgeon to the Central London Throat and Ear Hospital.

POWELL, J. A., M.B.—House Surgeon to the Worcester General Infirmary, *vice* M. B. Shirley, L.R.C.P., resigned.

STUART, WILLIAM, M.B. and M.C. Aberdeen.—Medical Officer to South District, Stratton Union, *vice* John Henry Tuke, resigned.

VACANCIES.

BLOFIELD UNION.—Medical Officer to the Acle District, in succession to Mr. W. H. Cufaude, deceased. Area, 24,151 acres. Population, 5,031. Salary, £70 per annum.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £130 per annum, with prospect of increase, residence, and coals, and gas. Candidates must be duly qualified. Applications, stating age, previous experience, with testimonials, to be sent to the Honorary Secretary, on or before June 12th.

CUMBERLAND INFIRMARY, CARLISLE.—House Surgeon. Board and lodging provided. Applications and testimonials to be sent to the Secretary (from whom can be obtained particulars of duties and qualifications), on or before June 10th. The appointment will be made on June 25th.

DEWSBURY UNION.—Medical Officer to the Heckmondwike District, in succession to Mr. James Turton, resigned. Area, 697 acres. Population, 9,283. Salary, £20 per annum.

EAST SUSSEX, HASTINGS, AND ST. LEONARDS' INFIRMARY.—Assistant Physician. Candidates must be duly registered Doctors or Bachelors of Medicine of some University of Great Britain or Ireland, or Fellows or Members of the Royal College of Physicians of London, Edinburgh, or Dublin. Applications, with testimonials, to be sent to the Secretary, not later than 10 o'clock on the morning of June 10th, the day of election.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free, &c. Candidates names must appear upon the Medical Register as being possessed of a medical and surgical qualification, and they must produce evidence of good moral character. Private practice strictly prohibited. Applications, with testimonials, to be sent to the Secretary, on or before June 11th. The election to take place on June 18th.

QUEEN'S COLLEGE BIRMINGHAM.—Professorship of Anatomy. Salary £262 10s. per annum. Applications with testimonials, to be sent to the Secretary, Joseph Lewis, 21, Paradise Street, Birmingham (from whom further particulars can be obtained), on or before June 30th.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, E.C.—Physician. Applications, with qualifications and testimonials, to be sent to the Secretary, on or before June 9th. The election will take place on June 10th.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Chair of Physiology. (*For particulars see Advertisement.*)

ST. MARY'S HOSPITAL, W.—Medical Superintendent. Salary £150 per annum, with board and residence in the Hospital. Candidates must be doubly qualified and registered under the Act, and must have filled the office of Resident Medical Officer at some General Hospital. Application to be sent to the Secretary, on or before June 10th.

DEATHS.

ALDRIDGE, J. P., M.D. and J.P., at Shirley House, Dorchester, on May 22nd, aged 71.

CUFAUDE, W. H., M.R.C.S., L.S.A., at Acle, Norfolk, on May 24th.

FINCH, F. C., M.D, late of Blackheath, Kent, at Pau, Basses Pyrénées, France, on May 28th, aged 70.

HALL, JOHN, M.D., at Woodley, Ruddington, near Nottingham, on June 2nd, in his 42nd year.

RULE, G. F. H., M.R.C.S., at 26, Elgin Crescent, W., June 4th, aged 40.

TWEEDIE, ALEXANDER, M.D., F.R.S., late of Brook Street, Grosvenor Square, at Bute Lodge, Twickenham, on May 30th, in his 90th year.

WALTER, JAMES KING, Surgeon-Major, retired list, Indian Army, at Mansfield House, South Hampstead, on May 28th.

NOTES, QUERIES, AND REPLIES.

Fellowship Examinations.—At the half-yearly final examination for the Fellowship of the Royal College of Surgeons, which was commenced on the 29th ult., when twenty-eight candidates presented themselves, the following questions on Pathology, Therapeutics, and Surgery were submitted to them, which they were required to answer between 10 and 2 o'clock, viz.:—1. Describe the course, diagnosis, and pathology of the Malignant Diseases of the Testicle. State the treatment. 2. Describe the processes by which an Aneurism may be cured spontaneously, and the surgical methods by which a cure can be brought about. 3. Describe the immediate and remote effects which may follow an Injury to the Spinal Cord in its several regions. 4. Discuss the differential diagnosis and surgical treatment of Ovarian Tumours.

The list of successful candidates cannot be published until confirmed by the Council at its next meeting.

An Elephantine Dose.—One of Barnum's secular elephants, "Allah," was attacked while in Cincinnati. Dr. Bowler, V.S., was called in, and relates his experience in the *Journal of Comparative Medicine.* The diagnosis having been made, he administered the following liberal dose:—Lard, 8 lbs.; linseed oil, 1 gallon; tincture of opium, 1 pint; syrup, 1 quart. The lard and oil were first mixed, and the other ingredients then added. The trunk was raised above the head, and the mixture poured down the throat through a large metal tube. The animal recovered.—*New York Medical Record,* May 17th.

COMMUNICATIONS RECEIVED—

THE REGISTRAR-GENERAL, Edinburgh; THE DIRECTOR OF THE ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND, London; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; Mr. M. D. MAKUNA, Pontypridd; THE SECRETARY OF THE ROYAL INSTITUTION, London; Mr. T. M. STONE, Wimbledon; Dr. HENRY BELCHER, Brighton; Dr. WYNN WESTCOTT, London; Dr. SHELLY, Hertford; Dr. DONKIN, London; Mr. M. BECHER, London; Dr. J. W. MOORE, Dublin; THE SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY, London; Dr. YARROW, London; Dr. BAINES, London; OUR VIENNA CORRESPONDENT; THE SECRETARY OF THE INTERNATIONAL HEALTH EXHIBITION, London; Dr. TOSSWILL, Exeter; THE SECRETARY OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY, London; THE SECRETARY OF THE BRITISH MEDICAL ASSOCIATION, London; THE SECRETARY OF THE ROYAL COLLEGE OF PHYSICIANS, London; Dr. JAMES ANDERSON, London; Messrs. PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet — British Medical Journal — Medical Press and Circular — Centralblatt für Chirurgie — Gazette des Hôpitaux — Gazette Médicale — Pharmaceutical Journal — Wiener Medicinische Wochenschrift — Révue Médicale — Gazette Hebdomadaire — Nature—Boston Medical and Surgical Journal—Louisville Medical News — Centralblatt für Gynakologie — Le Concours Médical — Centralblatt für Klinische Medicin—Philadelphia Medical News —Le Progrès Médical — New York Medical Journal — Students' Journal and Hospital Gazette — New York Medical Record—The Edinburgh Clinical and Pathological Journal—The Philadelphia Medical Times—Centralblatt für die Medicinischen Wissenschaften —Berliner Klinische Wochenschrift—Maryland Medical Journal—Weekblad—The Therapeutic Gazette—National Anti-Compulsory Vaccination Reporter—The City Press, May 28th—Ophthalmic Review—The Journal of Nervous and Mental Disease—Canada Medical and Surgical Journal—The Birmingham Medical Review —Archives Générales de Médecine — The Analyst — Edinburgh Medical Journal — The Australian Medical Journal — Friendly Greetings—The Girls' Own Paper—The Sunday at Home—The Leisure Hour—Boys' Own Paper—The Veterinarian—The Glasgow Medical Journal—Centralblatt für Therapie—The Dublin Journal of Medical Science.

APPOINTMENTS FOR THE WEEK.

Friday, June 6 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Edward Albert Schäfer, F.R.S., "The Analysis of Voluntary Muscular Action."

ROYAL INSTITUTION, 8 p.m.—Mr. Willoughby Smith, "Electric Induction Experiments."

Saturday, June 7.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL INSTITUTION, 3 p.m.—Professor Bonney, "Microscopical Geology."

Monday, June 9.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 8 p.m.—Casual Communications by Messrs. W. St. George Elliott, W. E. Harding, David Hepburn, &c. Mr. Oakley Coles will read a Paper on "The Maintenance of Health amongst the Practitioners of Dental Surgery."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Edward Albert Schäfer, F.R.S., "The Mechanism of Absorption."

Tuesday, June 10.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND, 8 p.m.—The following Papers will be read:—A. W. Howitt, Esq., F.G.S., and the Rev. L. Fison, M.A., "The Deme and the Horde;" C. A. Gollmer, Esq., "African Symbolic Language;" S. M. Curl, Esq., M.D., "Phœnician Intercourse with Polynesia."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 p.m. — Mr. Arbuthnot Lane, "Three Forms of Spinal Deformity;" Dr. W. H. Broadbent, "On a Particular Form of Amnesia—Loss of Nouns;" Dr. Sharkey, "Embolism of the Right Middle Cerebral Artery, producing Left Hemiplegia and Hemianæsthesia—Absorption of a large portion of the Right Hemisphere—Death seven years later;" Dr. Matthews Duncan, "On Albuminaria with Parametritis;" Dr. Stephen Mackenzie, "Observations on the Weight of the Thyroid Body."

Wednesday, June 11.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 p.m.—The following Papers will be read:—H. Franklin Parsons, M.D., "Some Observations on the Etiology of Diphtheria;" John Wortabet, M.D., "Epidemiological Notes during the Autumn of 1883 in Beyrout, Syria." Office-bearers for the ensuing year will be nominated.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Professor Sir Henry Thompson will deliver his First Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m.—The following Papers will be read:—Dr. J. Anthony, on "The Camera Lucida;" G. F. Dowdeswell, on "Some Phenomena of the Red Blood Corpuscles of Vertebrates, with reference to the Occurrence of Bacteria normally in Living Animals;" C. D. Ahrens, on "A New Polarizing Prism;" G. F. Dowdeswell, on "The Constancy of Specific Morphological Characters in the Bacteria."

Thursday, June 12.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, June 13.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Professor Sir Henry Thompson will deliver his Second Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

ROYAL INSTITUTION, 8 p.m.—Prof. Dewar, "Researches on Liquefied Gases."

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Epidemiological Society of London.

(Continued from page 762.)

Hospital Gangrene.

As an associate of scurvy, this has been long the subject of medical observation in India. The writings of Trotter are full of evidence of the fact that, for a considerable time after the introduction of lime-juice had freed the seamen of our Royal Navy from typical scorbutus, the men suffered greatly from sloughing ulcers—produced by slight causes, such as the contact of a drop of hot pitch with the skin—which were evidently of scorbutic origin. As I have already stated, a scorbutic tendency is most extensively prevalent among the native population of India, and most especially in the provinces of Behar and Scinde; and scorbutus has repeatedly attacked our European-Indian forces in sieges, as at Lucknow, and in campaigns, as in the first Burmese war, when fresh vegetables and flesh meat became scarce. The writings of Hennen and other military surgeons show that malignant ulcer, of scorbutic origin, also committed great ravages among our troops in the Peninsular war. And consequently, unless the greatest care be taken to supply prisoners and detached parties of European and native troops with an adequate and sufficiently varied diet, scorbutus in its full development, and even more dangerously in its masked forms — malignant phagedænic ulcer, dysentery, &c.—may be expected to prevail among them. In 1818 Dr. J. Adam observed an outbreak of "an epidemic malignant ulcer, or hospital gangrene," which occurred in a body of native troops belonging to the Nerbudda Field Force. Only one European soldier was attacked, in consequence of the application of a blister to the side. Here the ulceration was moderate and recovery speedy. A boil, or small ulcer, consequent upon a scratch or bruise, would cease to discharge pus; its granulations would become pale and slough rapidly, with an acute burning pain and extreme sensibility of the surrounding parts. Fever and great constitutional distress would set in, and the destruction of parts would extend equally in all directions, passing deeply into the cellular tissue and muscles. The colour of the sphacelated parts was a dusky grey. There was very little discharge. It appeared as if sudden death had seized the parts. Bone would be laid bare; there was great loss of soft parts, which had to be removed by scissors, and there was a tendency to alarming hæmorrhage. The general symptoms at this stage "were such as mark a high degree of the remittent fever of the natives." "In no instance did death ensue." "The disease resembled exactly what has been described to occur in the hospital gangrene of Europe." Dr. Adam observed that, on

this occasion, the native soldiers suffered greatly, while the European troops were almost free from the scourge, because the latter were well fed and clothed, while the former were very wretchedly accommodated and indifferently clad and nourished, not only the poor syces and grass-cutters, but also the higher classes of native soldiers depriving themselves, with a view to saving, of many essentials of comfort, more especially in the field, where they are most required.[14]

In 1824, Mr. J. Leslie witnessed an outbreak of "gangrenous ulcer" in the 65th Regiment of Native Infantry at Prince of Wales's Island.[15] The disease, of which a very careful description is given, was hospital gangrene. There were 281 cases in eight months; of these 40 were fatal. The limb was amputated in nine cases, four of which were fatal. Among the ascertained causes were an extremely meagre diet of rice and vegetables, usually of very inferior quality, insufficient covering, and overcrowding.

In June, 1826, Superintending Surgeon Longstaff reported[16] that "intractable ulcers, of an erysipelatous and sloughing character," had long been numerous in the hospitals at Benares and at others in that division. Common boils, on being laid open or bursting spontaneously, immediately degenerated into phagedænic ulcers. This tendency had existed for more than a twelvemouth.

Mr. J. C. Geddes gave[17] a very graphic account of "malignant ulcer and hospital gangrene," as he observed it, in the early part of 1827, at Prince of Wales's Island, where, as we have stated above, this malady prevailed among the Sepoys in 1824. The disease was most severe and fatal. A common sympathetic bubo often degenerated into a phagedænic ulcer, occupying the whole extent of the groin, spreading to and laying bare the abdominal muscles, and then exposing the peritonæum; extending down the thigh and laying bare the artery, which was seen pulsating, but which displayed extraordinary power of resisting the ulcerative process, lying untouched in a mass of gangrenous matter until the patient sank exhausted. Amputation was freely resorted to. Mr. Geddes and Dr. Grant amputated 35 limbs, besides toes and fingers. Exactly half of those so treated recovered.

Some years later there was great prevalence of phagedænic ulceration of a most severe and obstinate character among our native troops in Arracan, when the constitutions of the men had become broken by Arracan remittent fever. (*Vide supra*, p. 737, vol. ii. for 1883.)

In 1843, the 4th Regiment Madras Native Infantry suffered considerably from sloughing ulcers at Singapore. Ephemeral and quotidian fevers and rheumatism were prevalent. Phagedænic ulcers began to appear in the month of September, and continued to increase up to the end of November, when the cases became less numerous and severe. The worst description of ulcer was generally situated about the lower third of the leg, or on the ankle and foot, and usually proceeded from some slight injury or from the pustules of itch. The expression was anxious, the tongue white and flabby, and the lower limbs frequently somewhat œdematous. Several patients died, "either sinking from the effects of constitutional irritation, or being reduced to a state of excessive debility, were carried off by colliquative diarrhœa after the sloughs had separated."[18]

Kenneth Mackinnon remarked that the hospital gangrene which appeared among the wounded after the battles on the Sutlej, in the first Sikh campaign, offered a fine illustration of the manner in which the atmosphere may be poisoned by overcrowding and foul discharges not carefully removed. "The military surgeon," he said, "should not overlook the fact that the canvas of tents is a substance to which impure effluvia are likely to attach themselves." In the next campaign things were better managed, and the disease did not appear.

At Chittoor (Southern Division of Arcot, Madras Presidency) sloughing ulceration prevailed to a great extent at particular periods, as in the years 1830, 1833, 1837, and 1838. It was supposed to arise from the causes which produce fever. "*The inhabitants of the village were as liable to this form of ulceration as the prisoners, and were affected precisely at the same periods.*" I emphasise this fact, because, when we place it beside the fact which will presently be noticed, that sloughing phagedæna prevailed extensively in the district of Indore, Bombay Presidency, it appears nearly certain that this malady does, to say the least occasionally, assume an epidemic or widely spreading endemic character. In the jail, ulcers formed a large proportion of the admissions. Many of the sores sloughed. In all these cases the general health was more or less disordered, many of the patients had occasional paroxysms of fever, others suffered from diarrhœa, and the tongue was generally thickly coated with yellow fur. In cases where the constitution had been severely injured by repeated attacks of fever, the ulcers, having degenerated into large sores, became covered with a thick slough of a dirty white colour, attached to an irritable bleeding surface, which, on falling off, exposed the muscles, and sometimes laid bare the bones of the leg (the lower extremities only being attacked) to a considerable extent. In these severe cases diarrhœa was generally present.[19]

In and about the year 1833, hospital gangrene was very prevalent among native prisoners in Bengal; the exciting cause being frequently irritation by the ankle-irons, before the leather *mozas* were brought into general use as a protection to the skin. This, as well as the attendant dysentery, was attributed to scurvy. A valuable chapter on this subject will be found in James Hutchinson's "Observations on the General and Medical Management of Indian Jails, &c.," 1845. That and other old records of scurvy and gangrene in Indian jails deserve the fullest attention of medical officers at present serving in the East, seeing that the returns for 1881 show that 405 cases of scorbutus, and 115 of "gangrene and phagedæna," occurred among the jail population in that year. The deaths from scurvy were only 9; those from gangrene and phagedæna, 48, of which 31 out of 45 cases occurred in the Andamans and Nicobars; and that there were, in 1882, 445 cases, with 13 deaths, of scorbutus, and 31 cases of "gangrene and phagedæna," with 13 deaths, among the prisoners—strong evidence that the old evil is always ready to break out afresh. My friend, Dr. Thomas W. Wilson, tells me that, while this disease was one of the chief scourges of Bengal native prisons, the late Dr. Wilkie, I think of Dinagepore, took him into his jail hospital, where, to his utter consternation, he being then inexperienced in Indian disease, upwards of a score of prisoners who had undergone amputation stood in a row, leaning upon crutches. In 1836, Mr. Chapman, of Purmah, wrote to the Medical and Physical Society of Calcutta upon the great prevalence of sloughing ulcers in his jail. The disease was clearly hospital gangrene.[20]

Kenneth Mackinnon wrote[21] that he once witnessed a very severe invasion of hospital gangrene in the jail hospital at Tirhoot, at a time when the weather was extremely close and sultry after a rainy season, during which the fall of rain had been unusually copious. The hospital was surrounded by stagnant water. The destructive process was not accompanied by much surrounding inflammatory action. It was what he might call an eating away of the textures, with highly fœtid discharge from the sores. The countenance had a sodden look. The conjunctiva tinged, perhaps not with bile, but with diseased blood.

Dr. J. P. Walker reported, in 1856,[22] that hospital gangrene was for some years a terrible pest in the Agra Central Prison, "affecting alike the weak and the strong, the sick and the healthy, the aged and the young, those who had spent years in prison and those but recently imprisoned. In 1853, when the total deaths, from all causes, were as 5·2 per cent. of the average strength, no less than 23·9 per cent., or nearly one-fourth of the whole mortality, was caused by 41 fatal cases of hospital gangrene. Everything was in vain tried as a prophylactic, and as a remedy; hygienic measures on a grand scale, resulting in the most scrupulous cleanliness, were found of no avail. The affected were isolated, and removed to the country for change of air, and the airy upper-storied rooms of the lofty gateways of the royal gardens at Secundra were converted into a hospital. Every plan of treatment —medical, surgical, and dietetic—recommended in standard medical works, and everything that theory suggested, was tried in vain, the pest remained unstayed; and, in a large number of the worst cases, death alone arrested the fearful ravages of the disease, and soothed the agonised tortures of the patients, the very remembrance of which is painful."[23]

In and about February, 1838, it was reported[24] that, at Agra, a scorbutic taint existed among the Sepoys; and that, whenever the skin got broken in any way, a malignant ulcer formed. At the same time, hospital gangrene appeared among the Sepoys at Saugor, and the disease broke out in Brett's Surgical Hospital in Calcutta. When I joined the service ten years later, in 1848, nothing was heard of this disease, either in Sepoy lines or in native jails, *in Lower Bengal*. Doubtless, in that decennium, sanitation had done much for both soldiers and criminals. Nevertheless, our experience of hospital gangrene in India did not then come to an end, as is shown in Dr. J. P. Walker's "Agra Report" cited above, and in the Jail Statistics of 1881 and 1882, which I have quoted.

In 1881, "gangrene and phagedæna" did not occur very frequently in the native army; but, wherever it appeared, the type of the malady was severe. In Bengal, there were four cases with one death; in Bombay, three cases with two deaths; and in Madras, five cases with one death. In 1882, there were 4 cases, of which 2 were fatal, in the Bengal Presidency, and 2 cases (1 fatal) elsewhere.

The old Chandney Native Hospital, Calcutta, was ill-situated in Durrumtollah. Some 45 years ago, sloughing was so destructive there as to lead the authorities to erect the Medical College Hospital, which was originally intended to relieve the other of its medical cases. The new building ought to have been reserved for surgical cases, for the old one continued to be infested with hospital gangrene.

In 1854 Dr. K. Mackinnon alluded to the fact that wounds made in operating there were apt to take on an erysipelatous and sloughing action, especially during the rains. An investigation of the history of this place convinced me that, as far as I could trace back, *hospital gangrene had been endemic in this building*. That is to say—while it frequently happened that compound fractures, amputations, lithotomy cases, &c., all of which were very numerous then, often recovered as well and as rapidly as they could do in any hospital (the only drawback being that the scalp-wounds, which were extremely common, generally took on an erysipelatous character, ranging from a slight evanescent blush of inflammation down to most extensive sphacelus); on the other hand, suddenly, as it would appear from some change of wind or weather, the surgeon, on paying his morning or evening visit, found that nearly every unhealed surface—ulcers, stumps, wounds which, at the last visit, only presented a thin line of healthy granulation—had become overspread with a thick tenacious diphtheria-like exudation, betokening gangrene. Some of the least promising of these cases did remarkably well, but a large proportion were fatal. I obtained from my friend, Dr. Herbert Baillie, the statistics of the gangrene which prevailed there for a period of four years and a half—1855-59. There was a total of 519 surgical operations, in 102 of which the issue was fatal. Gangrene attacked 96 of the 519 persons operated on, and 70, who were attacked with gangrene, died. This table did not include the many cases in which gangrene attacked ulcers and accidental wounds.

In the winter of 1859, I was requested by my friend, the late Dr. Allan Webb, surgeon to the institution, to visit its wards daily for a month, and to report the result for the information of the governors. Dr. Webb informed me that what he considered to be true hospital gangrene had not made its appearance in his ward since the year 1855; but that, since he had held charge, there had been scarcely any time at which he had not found reason to fear that any case of wound or injury, whether slight or severe, or any patient upon whom a surgical operation had been performed, however favourable in appearance all concurrent circumstances might be, was liable suddenly to be attacked with mortification. On my first visit (on the 29th January), I saw 31 cases of wound or ulcer. Seven of these patients had undergone surgical operations. In six of the 31 cases, the wound or ulcer had a more or less unhealthy character. The nature of these unfavourable cases, taken together with what I had learnt from Dr. Webb, prepared me to believe that, while the generality of wounds did well, many were attended with unhealthy inflammation, tending to gangrene, for which the nature and severity of the accidents or operations were insufficient to account. On the evening of the 1st of February, my attention was drawn by Dr. Webb to a sudden and remarkable change for the worse which came over several of the patients suffering from wounds. They became feverish, or had distinct attacks of intermittent or remittent fever, their wounds gaped, were raised and flabby at the edges, or began at once to slough. These portentous changes were at first most observable in certain cases of flap wound. Several deaths followed this outbreak, and several cases of rather extensive gangrene did well, although their recovery was not rapid. The case of a native man who had been operated upon for strangulated hernia particularly struck me; there was a clean firm linear cicatrix which would have been perfect had not one bright red granulation, like a little carnelian button, remained at the middle of its course. Just as the man was about to be discharged, there was an appearance as if the surface of the granulation had been delicately touched with cigar ash, it being coated with a fine greyish-white film. Then most destructive gangrene rapidly set in and spread.

The native hospital and its most insanitary neighbourhood were afterwards improved, but the place was

[23] The mode of treatment successfully adopted by Dr. Walker will be cited below.
[24] *Ibid.*, N. S., vol. iii., p. 177.

at last condemned and disused, the Mayo Hospital having been built for its patients.

Assistant Surgeon R. N. Roy, published[25] a report of an outbreak of hospital gangrene which occurred in the Allyghur Dispensary in March, 1874. Whenever the hospital accommodation is close and bad in India, and the patients are the subjects of scorbutic or malarious cachexia, hospital gangrene may be anticipated.

We, however, have evidence that disease of this character may suddenly make its appearance and become very prevalent in a district apart from the influence of poor food and overcrowding. Dr. T. Beaumont reported[26] that sloughing phagedæna was almost unknown in Indore until the rainy season of 1871, when a few cases were seen. During the rainy season, and up to the end of 1872, it became so very prevalent that it was feared it was about to become established as an endemic disease. In the five months ending the 31st December, 315 cases came under observation; of these 51 proved fatal. Any part of the body was liable, usually the leg, foot, or ankle. In all cases it attacked some pre-existing breach of surface, as a slight abrasion from an ill-fitting shoe. There was nothing exceptional in the season or food supply.

Prophylaxis and Treatment.

As it has been found in the very large majority of outbreaks of hospital gangrene that some or all of the following causes have been at work: Scorbutus or what amounts to the same thing, poverty, an innutritious staple of diet, such as the new common *dasee* rice of Bengal; a diet not sufficiently full and varied, and wanting in flesh, fish, oil and antiscorbutic fruits and vegetables, over-crowding, especially in hospitals where surgical and medical cases are not separated, insanitary *entourage*, exposure to vicissitudes of temperature, over-work or fatigue, all within the influence of marsh miasma—our chief means of prophylaxis lie clearly before us. With prisoners, abrasion by the leg irons; and with soldiers, chafing by shoes and accoutrements are especially to be avoided, and the, at first, trivial sores thus caused should always be carefully treated. I think that the histories show that recourse to amputation is not to be wholly put aside:—I need scarcely add that I should not have tried it until all other means had been tested and had failed. In the Tirhoot Jail hospital, Kenneth Mackinnon "found no local application do good but the pure undiluted nitric acid, applied on lint, making the parts smoke, and literally burning out the whole diseased surface." So, also, in the Indore outbreak of 1871, Dr. Beaumont found no treatment so successful as the thorough application of nitric acid. My friend, the late Dr. J. Sutherland, used *irrigation* with marked success;[27] and Dr. J. P. Walker places the highest value upon the local application of burnt alum and of an ointment composed of powdered alum (not burnt), catechu, balot (extract of *Berberis lycium*), opium, common bazar soap, and water.[28]

(*To be continued.*)

Solidified Creosote.—In its application to carious teeth, creosote is often inconvenient in consequence of its fluidity producing ill effects upon the mucous membrane of the mouth. This may be obviated by giving to it a gelatinous solidity by adding ten parts of collodion to fifteen of creosote. This, besides being more manageable than liquid creosote, also closes up the orifice in the tooth, preventing the accession of the air to the dental nerve.—*Progrès Médical*, April 19th.

AN EXAMINATION OF THE THEORY OF AËRIAL DISSEMINATION OF SMALL-POX INFECTION.

By MONTAGUE D. MAKUNA,
Late Medical Superintendent of Fulham Small-pox Hospital.

(Concluded from page 766).

The Year 1880.

This was not an eventful year, as the small-pox epidemic was on the decline. There were 475 deaths from it in London, of which 3 were in Kensington, 49 in Fulham, including 48 in Fulham Hospital, and 1 in Chelsea. The Metropolitan Asylums Board Hospitals admitted 1,916 cases, of which 46 were from Fulham, 40 from Kensington, and 17 from Chelsea. Highgate Small-pox Hospital admitted 1 from Fulham O. S. A., and 1 from Kensington O. S. A. The Health Officers reported 51 in Fulham, 51 in Kensington, and 8 in Chelsea as the incidence of the disease.

January.—Fulham Hospital admitted 45 acute cases, viz., 5 from Fulham, 4 from Kensington, 4 from Chelsea, 20 from Islington, 5 from St. Pancras, 2 from Wandsworth, 2 from Marylebone, and 1 each from Paddington, Strand, and St. George's. The known incidence of disease was 6 cases in Fulham, 8 in Kensington, and 4 in Chelsea. The weekly number of cases under treatment during the five weeks ending 31st January, was 24, 32, 31, 36, and 33.

Fulham Cases.—A labourer from 56, Farm Lane, C. C., infected house. (2) A child from 17, Fane Street, ½ mile R., on the 23rd to Fulham Hospital. (3) A female from 19, Chesson Road, ½ mile R., on the 29th. (4) A labourer from 1, Elizabeth Place, ¾ mile R., on the 29th, from a fatal concealed case in Hilmer Street. (5) A labourer from 36, Ancill Street, 1 mile R., on the 1st, from a concealed case. (6) A case treated at Vanstone Place, ½ mile R., reported on the 28th.

Kensington Cases.—(1) A child from 2, Finborough Road, C. C., on the 23rd. She came from Paris on the 16th. (2) A domestic from 33, Coleherne Road, ½ mile R., on the 6th. (3) A domestic from 24, Harcourt Terrace, ½ mile R., on the 13th. She came from Yorkshire only a week before. (4) A newspaper boy from 141, Earl's Court Road, ¾ mile R., on the 27th. By visiting in Child's Place, where there were cases of small-pox. (5 to 7) Three in Child's Place, ¾ mile R., caused by concealed cases; 2 at 14, reported on the 20th and 22nd; and 1 at 13, on the 28th. (8) A boy in Goldborne Road, O. S. A.

Chelsea Cases.—(1 and 2) Two children from 39, Slaidburn Street, ¾ mile R., on the 8th and 24th. (3) One from 94, Arthur Street, 1 mile R., on the 23rd. (4) One from Leader Street, O. S. A.

February.—Fulham Hospital admitted 62 acute cases, viz., 18 from Fulham, 12 from Kensington, 4 from Chelsea, 15 from St. Pancras, 4 from St. George's, 6 from Wandsworth, 2 from Islington, and 1 from St. Giles's. The known incidence of disease was 18 in Fulham, 15 in Kensington, and 4 in Chelsea. The weekly number of cases under treatment was 40, 54, 50, and 53.

Fulham Cases.—(1) A domestic from 14, Farm Lane, C.C., on the 14th. She was sent home ill from the place of her service; she took it from 5, Langston-place, where a wake had been held on a fatal case. (2) A plasterer from 3, Rickett Street, C.C., on the 17th. A concealed case. (3) A charwoman from 6, Rickett Street, C.C., on the 20th. From a concealed case. These cases were discovered by house to house visitation. (4 and 5) Two sisters from 4, Hermitage Villas, ½ mile R., on

the 1st and 16th. (6) A labourer from 17, Fane Street, ½ mile R., on the 4th. Infected house. (7 to 11) A domestic from 5, Rear Gate, ½ mile R., on the 13th. Sent home ill from 8, Seagrove Road, an infected house and a baby farm. She gave it to the lodgers in the house, on the 22nd, 24th and 27th. (12) A tailor from 5, Langston Place, ½ mile R., on the 14th. The house in which a wake was held over a fatal case. (13 and 14) A carpenter from 31, Cornwall Street, ½ mile R., on the 25th. From a house opposite. (15) A fitter from 3, Edward's Cottages, ¾ mile R., on the 15th. By visiting friends in Church Street, Battersea. (16) A labourer from 20, Anselm Road, ¾ mile R., on the 19th. (17) A publican from 13, Star Lane, ¾ mile R., on the 27th. From a concealed case at home. (18) A navvy from 8, Kennett Road, 1 mile R., on the 14th. (19) A private case was treated in Vaunston Place, ½ mile R., reported on the 14th.

Kensington Cases.—(1) A female from 104, Adrian Terrace, C.C., on the 14th. (2) A painter from 36, Ifield Road, C.C., on the 21st. A fatal case occurred in the house in October last. (3) A painter from 5, South Street, C.C., on the 23rd. (4) A sick-visitor from 15, Redcliffe Gardens, ⅛ mile R., on the 3rd. Believed to have caught it at a public concert. (5) A domestic from 20, Coleherne Road, ½ mile R., on the 14th. (6) A carpenter from 18, Kempsford Gardens, ½ mile R., on the 23rd. (7) A labourer from 3, North Row, ¾ mile R., on the 3rd. By visiting infected houses either in Child's Place, or Hilmer Street, Fulham. (8 and 9) A mother and child from 18, Ashley Cottages, ¾ mile R., on the 9th. (10) A domestic from 38, West Cromwell Road, 1 mile R., on the 21st. From the infected clothing of her companion who was a patient in July last. (11 to 13) Two in 13 and one in 14, Child's Place, ¾ mile R. Infected houses. (14) A servant from Industrial School, suffering from measles took the disease in the hospital. (15 and 16) One each from Stamford Street, and Notting Hill Square, O.S.A.

Chelsea Cases.—(1) A labourer from 63, Blantyre Street, ¾ mile R., on the 10th. By visiting his father at 21, Seagrove Road. (2) A dressmaker from 10, Riley Street, ¾ mile R., on the 25th. (3) A domestic from 34, Church Street. Only two days at the address. (4) One from Elm Park Gardens O. S. A.

March.—Fulham Hospital admitted 23 acute cases, viz., 8 from Fulham, 6 from Kensington, 3 from St. George's, 2 from Strand, 1 from St. Giles's, 1 from Wandsworth, 1 from Paddington, and 1 from Westminster. The Medical Officers of Health reported 10 in Fulham, 7 in Kensington, and 1 in Chelsea. The weekly number of cases under treatment was 52, 44, 33 and 25.

Fulham Cases.—(1) A horse dealer from 6, Roxby Place, C. C., on the 6th. From a concealed case. (2) A dressmaker from 5, Little Stamford Street, ½ mile R., on the 2nd. Took it from 5, Rear Gate, where there have been cases. (3 to 6) Four from 19, Chesson Road, ¾ mile R., on the 4th, 5th, and 2 on the 21st. A case from the same house in January. (7) A baker from Richmond Place, ½ mile R., on the 11th. (8) One from 61, May Street, ¾ mile R., on the 27th. (9) A private case treated in Anselm Road, ¾ mile R.

Kensington Cases.—(1) A milkman from 15, Redcliffe Mews, ½ mile R., on the 3rd. (2) A domestic from 24, Eardley Crescent, ½ mile R., on the 5th. (3) A domestic from 5, Redcliffe Square, ½ mile R., on the 21st. (4 to 6) Three from O. S. A., viz., one each from Kensington Place, Stamford Road, and 109, High Street.

April.—Fulham Hospital admitted 27 acute cases, viz., 2 from Fulham, 6 from St. George's, and 3 from St. Giles's. The weekly number of cases under treatment was 18, 18, 17, 16 and 15. The three Fulham cases, including desperate case, occurred in O. S. A. The small-pox epidemic was on the decline in the metropolis during the year, and it followed the same general law in the S. A., for although we admitted 45, 62 and 23 acute cases in January, February and March respectively, it had no influence on the S. A. through air. It cannot be said that there were no susceptible individuals present there, because in the following year, when Mr. Power made his investigations, S. A. was specially infected as in the years 1878 and 1879.

May.—Fulham Hospital admitted 27 acute cases, viz., 2 from Fulham, 3 from Kensington, 1 from Chelsea, 2 from Paddington, 8 from Islington, and 7 from St. Pancras. The weekly number of cases under treatment was 11, 11, 16, and 23. The two Fulham cases were from Clarence Villas, 1 mile R., on the 27th. The Kensington and Chelsea cases were from O. S. A.

June.—Fulham Hospital admitted 26 acute cases, viz., 5 from Fulham, 2 from Kensington, 9 from Islington, 3 from St. George's, 2 from St. Giles's, 2 from Paddington, 2 from Marylebone, and 1 from St. Pancras. The weekly number of cases under treatment was 20, 24, 29, and 26.

Fulham Cases.—(1) One from Dawes Lane, ¾ mile R., on the 4th. (2) One from Model Buildings, 1 mile R., on the 29th. Infected house. (3) One from Grove Terrace, 1 mile R., on the 17th. (4 and 5) Two from Goldhawk Road, and West London Hospital, O. S. A. The two Kensington cases were, a domestic from 7, Bolton Gardens, ½ mile R., on the 12th, and one from Silchester Terrace, O. S.A.

July.—Fulham Hospital admitted 16 acute cases, viz., 3 from Fulham, 2 from Kensington, 8 from Islington, 1 from St. George's, 1 from Paddington, and 1 from St. Pancras. The weekly number of cases under treatment was 19, 15, 17, 17, and 14.

Fulham Cases.—(1) One from 32, Dieppe Street, 1 mile R., on the 3rd. (2) One from 4, Grove Terrace, ¾ mile R., on the 17th. (3) One from Portland Street, O. S. A.

Kensington Cases.—(1) A domestic from 7, Redcliffe Square, ½ mile R., on the 23rd. (2) A pupil teacher from 338, Fulham Road, ½ mile R., on the 12th. (3) A private case at 78, Cromwell Road, 1 mile R., reported on the 17th. He contracted the disease at Folkestone.

August.—Fulham Hospital admitted 10 acute cases, viz., 1 from Fulham, Elizabeth Cottage, ¾ mile R., 1 from Kensington, O. S. A., 4 from Islington, 2 from St. Pancras, 1 from Paddington, and 1 from St. Giles's. A private case was treated at 3, Eardley Crescent, ½ mile R. The weekly number of cases under treatment was 11, 12, 11, and 10.

September.—Fulham Hospital admitted 14 cases, viz., 1 from Fulham, O. S. A., 6 from Kensington, 1 from St. George's, 1 from Paddington, 1 from Marylebone, 2 from Islington, and 2 from St. Pancras. The weekly number of cases under treatment was 12, 12, 14, 18, and 10.

Kensington Cases.—(1) A domestic from 6, Redcliffe Gardens, ½ mile R., was sent home ill to 13, South Place, C. C., on the 30th. The following day she went to St. George's Hospital as an out-door patient, and on the 1st drove down in a cab to the workhouse, from which place she was removed to the hospital. (2 and 3) Two from 13, South Street, C. C., the house where the above case went home ill, one on the 13th, and the other walked to the hospital on the 15th. (4) A domestic from 3, Cathcart Road, ½ mile R., on the 11th. (5) A domestic from 1, Lily Terrace, 1 mile R., on the 8th. She contracted it in Paris, nursing her sister. (7) One from Edenham Street, O. S. A.

October.—Fulham Hospital admitted 3 acute cases, viz., 2 from Kensington, O. S. A., and 1 from Islington.

*

The weekly number of cases under treatment was 6, 9, 7, and 7.

November.—Fulham Hospital admitted 5 acute cases, viz., 1 from Fulham, O. S. A., 1 from Kensington (330, Fulham Road, ½ mile R.), 2 from St. George's and 1 from Marylebone. The weekly number of cases under treatment was 4, 3, 4, and 3.

December.—Fulham Hospital admitted 15 acute cases, viz., 10 from Islington, 2 from Holborn, 1 each from St. George's, St. Pancras, and Strand. There were 55 convalescents transferred from other hospitals. A case from Fulham, O. S. A., was sent to Stockwell Hospital. The weekly number of cases under treatment was 1, 1, 44, 38, and 63.

With the close of the year 1880 ends the history of the spread of small-pox in Kensington, Fulham, and Chelsea, between which three districts Fulham Hospital is situated, previous to Mr. Power's investigations. It has not been my intention to comment on his observations during the following three months, viz., January, February, and March, 1881. From my personal investigations during the years 1877–80, I had formed definite ideas how small-pox spreads in a commonplace manner, whatever mode it may be—through exposure of the sick, want of isolation, washing infected clothing in laundries, concealment of cases, mismanagement of hospitals, &c., and this has been abundantly testified in the narration of the history year after year. Those who have carefully perused Mr. Power's Report (Supplement to the "Tenth Annual Report of the Local Government Board, pages 302–358), will agree with me when I say that he bases his theory on assumptions and general statements—mere negation of the knowledge of the spread of the disease. I have clearly demonstrated that the incidence of the disease in Kensington, Fulham, and Chelsea, separately, is quite a different thing from admissions to the Metropolitan Asylums Board Hospitals. Again, the calculation of the incidence in the C. C. and surrounding rings, taking the houses collectively in the three districts in the respective areas at certain times, is erroneous; for I have shown that in those months when the disease was most prevalent in the S. A. of Fulham, it was not so in the S. A. of Kensington, and so on, irrespective of multifarious conditions favouring the spread of the disease narrated at the commencement of this paper.

Before I complete this paper I shall briefly notice Mr. Power's conclusions. At page 322, he states :—"It will now be convenient to sum up the results that have, up to this point, been established in the present inquiry. (1) There has been in each epidemic period an excessive incidence of small-pox on houses in the neighbourhood of the hospital as compared with more distant houses in Chelsea, Fulham, and Kensington. (2) The percentage of houses invaded in the neighbourhood of the hospital has become gradually smaller as the distance of the houses from the hospital has increased. This gradation has been very exact and very constant. (3) Houses upon the chief lines of human intercourse with the hospital have not suffered more than houses lying in other directions from the hospital. (4) In point of time, there has been a very marked relation between the varying use of the hospital and the manifestations of excessive small-pox in the neighbourhood. This relation has not shown itself while the use of the hospital has been for convalescents only. (5) The appearance of excessive small-pox in houses around the hospital has never been delayed until the hospital has become full or nearly full. It has been always most remarkable at the time when admissions to the hospital were beginning to increase rapidly. In the succeeding months of active operations, though the use of the hospital may have gone on increasing, the excess of small-pox upon the neighbourhood has habitually become less marked. (6) On comparison of different epidemics, an almost constant ratio is observed between the amount of the hospital operations and the degree of excess of small-pox on the neighbourhood."

In describing the conditions of the population and the houses in the S. A., I have clearly shown how his first three conclusions can be justified without having recourse to the theory of infection. His statement "that gradation has been very exact and very constant" is founded on inexact figures, varying with unequal admissions to metropolitan hospitals, with concealment of cases, private cases, and admissions to Highgate Hospital. As regards the fourth conclusion, it has been noticed that, with increasing use of the hospital, there has been to a certain extent increasing inter-communication between the hospital and the outer world. But there is one thing to be said, and that is, the existence of the disease was never fully ascertained from the beginning and primary cases isolated. We all know that the period of convalescence is not so infectious as the pre-eruptive and vesicular stages of the disease, as has been demonstrated by Panum, of Copenhagen, and Thomas, of Leipzig, and as has been narrated in my paper on "The Pre-eruptive Stage of Small-pox" (see *Medical Times and Gazette*, May and June, 1882). His fifth and sixth conclusions are meant to add force to his calculations based on unsound premisses. Further on he states :—"At the time of the opening of Fulham Hospital four years ago, the Managers of the Metropolitan Asylums Board were nowise unfamiliar with the accusations to which small-pox hospitals are liable, and they applied their experience with great intelligence and forethought. The hospital buildings are, as has been shown, thoroughly well enclosed and separated from populous parts of the district by wide intervals of open ground. Also, they are remote from traffic routes, so that few persons besides those having business at the hospital need to go near it."

It must be evident to every reader of this paper that Mr. Power's complimentary advocacy of the management of the Fulham Hospital is a grievous failure, and *would* lead one to speculation and philosophy. His description of the current doings of the hospital "from the first regulated with the express purpose of avoiding all needless communication with the outside," is, to say the least, a picture without the original after all, and not applicable to the years 1877–80. His last three conclusions are a sequence of his reasoning from the evidence placed before him, viz. :—"(7) The machinery of the hospital administration, with inclusion of defects in that machinery, does not account for the peculiarity of small-pox incidence within the three parishes of Chelsea, Fulham, and Kensington since the establishment of the hospital. (8) There must have been some condition or conditions operating to produce the observed distribution of small-pox around the hospital that have pertained to the hospital as such, and that have been in excess of the condition of small-pox extension as usually recognised."

"To these propositions it should be seen to be a corollary, that every detail in the machinery of the hospital that is within the province of the hospital administration becomes of more importance to the protection of the neighbourhood than ever before. The apprehension that, outside of conditions over which man has control, there may exist other conditions conducing to the spread of small-pox from a hospital to its neighbourhood should be a reason for increased and not for diminished watchfulness in the management of the hospital, in order that such other conditions may be deprived, as far as human foresight can deprive them, of the opportunity of exerting their influence."

"(9) During the present epidemic period, and most probably during former similar periods, there has

arisen in the atmospheric circumstances of the time peculiar facility for the dissemination in an undamaged state of any matter that may have been given off from the hospital."

Like the judge who asks the gentlemen of the jury to leave out of their mind all they might have known and heard of the accused and to give their verdict in strict accordance with the evidence produced before the Bench, Mr. Power, disregarding all the facts bearing on the history of the epidemic in the districts of Fulham, Kensington, and Chelsea because he could not have access to them; disregarding the variety of the conditions of the population in those districts, which tend to the spread of the disease; taking for granted that admissions to Metropolitan Asylums Board Hospitals represented the incidence of the disease; overlooking the mismanagement of the institution; and disregarding the spread of the disease through concealment, laundries, non-isolation, and other commonplace modes — asks us to believe in his statistics, calculations, and arguments, and join him in enunciating the hypothesis of aërial infection, stamped with the authority of the Local Government Board, as a compromise with the agitators against the metropolitan small-pox hospitals, and thus end the *protracted* litigations of the managers of the hospitals. His conclusions might satisfy, as they have satisfied, the legal mind, but that cannot be considered a solution of the scientific problem. Mere negation of facts is not scientific evidence. I have placed before the readers all the facts I can command, and I ask them whether they are prepared to accept Mr. Power's nine conclusions quoted above. I for one look upon his theory and arguments, speculative as they are, as not applicable to the years 1877–80 and contrary to facts and my experience.

SOME OBSERVATIONS ON THE ÆTIOLOGY OF DIPHTHERIA.[1]

By H. FRANKLIN PARSONS, M.D.

(Abstract).

The author sought to bring together the principal known facts concerning the causation of diphtheria together with some of the hypotheses which have been propounded towards the solution of this hitherto unsolved problem, supplementing them by a few observations of his own.

Diphtheria, though the name is modern, has been known from early times. Until the middle of the present century it had, however, for nearly 100 years, been met with in this country only in the form of sporadic cases and limited outbreaks. Appearing in several parts of the country in 1855, the disease rapidly increased until, in 1859, it caused a mortality of 53 per 100,000. The death-rate then declined, with the exception of a second lesser rise in 1863, to 12 per 100,000 in 1867, about which figure it has kept constant ever since, latterly showing a tendency to rise.

A diagram was exhibited in which the curve of the death-rate from diphtheria during the past 30 years was shown and compared with those from scarlet fever and "fever," both of which, after large fluctuations in the first half of the period, had steadily declined in the second half, doubtless owing to the operation of the Public Health Acts, and the growth of public opinion as to the importance of preventive precautions.

[1] Read at the Epidemiological Society, on June 11, 1884.

The Registrar-General's remarks were quoted as to the probably large number of deaths from diphtheria which are returned under the headings of "croup" and "quinsy." The mortality from diphtheria, like that from scarlet fever, is greatest in the fourth quarter of the year, and between the ages of 1 and 5; but, unlike scarlet fever, it is more fatal to females than to males, and in rural districts than in towns. These points were illustrated by tables. Of the modes in which diphtheria may be supposed to originate, infection from a previous case is perhaps the only one which is certainly established. Examples taken from the author's experience were adduced.

The susceptibility of the disease varies greatly among different people, often being great in particular families. The disease is infectious in an early stage, before its characters are pronounced, and also after apparent recovery. The infection also attaches itself with persistence to houses, and may be conveyed by persons living in an infected air, who have not themselves suffered from the disease. The attendance of children at school is a frequent means by which the disease is spread, and there is reason to believe that it may be propagated from cases of sore throat of a mild character, such as frequently are prevalent at the time of diphtheria outbreaks, but which do not themselves present the typical features of the disease.

The infectious nature of the disease is also shown by the good effects which have followed well-considered and carefully executed measures of isolation and disinfection. Cases were quoted showing the length of the incubation period to be from two to five days. The hypotheses of the conveyance of the infection by the wind and by milk were touched upon.

Granting the infectious nature of diphtheria, and the difficulties in the way of tracking it, arising from latent causes, &c., it must still be admitted that it is frequent—more so than with small-pox or scarlet fever—to meet with outbreaks which cannot be traced to an antecedent case; and hence it is probable that the disease may arise *de novo*.

Diphtheria and scarlet fever are often associated, and the one disease has often appeared to have been contracted from the other.

Instances from the author's experience were given, and the nature of the connection between the two diseases was discussed.

The one disease is not protective against the other, nor is one attack of diphtheria protective against another. Diphtheria, moreover, may arise as an intercurrent affection in the course of other diseases, as measles, enteric fever, and erysipelas.

It would seem, therefore, that diphtheria should be classed in an intermediate position between the specific zymotics and the common inflammatory diseases; like erysipelas and puerperal fever, which may arise otherwise than from specific infection, but which propagate themselves readily by infection under appropriate conditions.

It is known that diphtheria can be imparted to the lower animals, but are there diseases of the lower animals differing in appearance from diphtheria, which may be capable of giving rise to that disease in the human subject? This question, still unsolved, is of especial importance in reference to milk; a number of outbreaks of diphtheria having been observed to follow the distribution of a particular supply of milk, though no opportunity for contamination with specific infection could be traced.

"Garget," suggested by Mr. Power, in reference on the Kilburn epidemic, in 1878, and "foot and mouth disease," were referred to.

Many authorities consider diphtheria to occur most frequently on a wet retentive soil; others that it occurs indifferently on soils of various nature. Some consider

it to prefer low, damp situations ; others, high, bleak, exposed sites. The author had not been able to attribute influence to any particular soil or situation, having met with the disease on clay, sand, limestone, on high chalk downs, and in the fens.

Can diphtheria be caused or propagated by insanitary conditions ? Judging from statistics it cannot, for the death-rate from the disease is higher in healthy rural districts than in the most unhealthy towns ; nor has it fallen, like that of fever, in consequence of the sanitary amelioration of recent years.

On the other hand, in practice it is often found that unsanitary conditions are present in houses in which diphtheria has broken out, and the author had an impression that unsanitary conditions, such as the inhalation of drain air and fœtid effluvia, overcrowding and dampness, were not without influence upon the occurrence and course of the disease.

The cause of the disease had at different times been sought for in various low vegetable organisms, as fungi —especially the oidium albicans. More recently Oertel and other German observers had found a micrococcus abundantly developed in the affected mucous membrane.

It seemed probable that the immediate cause of the disease would ultimately be found to be some low organism, which, while capable of passing its existence outside the human body, and perhaps habitually doing so, could nevertheless, under certain circumstances, take on a parasitic habit, and acquire toxic properties.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

EPITHELIOMA OF THE SIGMOID FLEXURE —SUPPURATION AND PERFORATION OF ABDOMINAL WALL—DEATH—AUTOPSY.

Under the care of Mr. BERKELEY HILL, F.R.C.S.
Surgeon to the Hospital.

(For these notes we are indebted to Mr. Victor Horsley, F.R.C.S., Surgical Registrar.)

Sarah Q., aged 66, was admitted under Mr. Hill, on August 1st, 1883. Patient stated that she had always been a healthy woman until the present illness began, with the exception of complicated confinements. Four months previous to her admission she had experienced some severe cramp-like pains in her abdomen. They came on suddenly while out walking one day ; she was obliged to get home, and after resting in bed for a day or two they entirely passed off, and she remained free from pain for five or six weeks. Then she one day experienced some difficulty in passing her motions. This continued for about a week, and was accompanied with a pain, similar in character and situation to that just mentioned. A doctor was called in, who ordered her "powders" and castor oil ; these opened her bowels, and took the pain away. The patient remained free from pain for three weeks, when she was seized with the old pain and inability to pass her motions, from which she was still suffering at the time of her admission.

State on Admission.—The abdomen is flaccid ; there is a distinct tumour, situated in the abdominal wall, most prominent in the middle line, one-and-a-half inches below the umbilicus, and extending into the right iliac region, and down to the pubes. It is pyriform in shape, and exceedingly tender and dull on percussion in the lower parts, and is hard and tense ; but the upper and more prominent part is smooth, rounded, softish and tympanitic. It can be slightly moved from side to side ; but this causes pain. There is no distension of the sigmoid flexure. The tumour is easily mapped out. It appears to be situated in the abdominal wall, and fluctuation can be felt in it. There is no redness or œdema of the surface ; neither are the veins distended. The patient's general aspect is pale and anæmic. Her temperature is 102° F. Skin moist. Pulse 78. There is no vomiting. Her bowels have acted this day, and twice yesterday. Tongue clean and moist. No evidence of failing strength or prostration. An examination of the chest showed it to be normal. Urine contained a little pus.

August 3rd.—Patient is free from pain. The bowels have acted. Turpentine stupes have been applied to the abdomen. That part of the tumour which was dull on her admission, has now become quite soft, and the fluctuation is very evident ; gurgling can be heard with the stethoscope. There is less tenderness. Pressure on the tumour does not reduce its bulk. The urine is to-day full of pus.

August 4th.—Mr. Hill reduced a piece of gut at the lower part of the swelling ; it went back into the abdomen with the characteristic slip and gurgle. The tumour is now less distinct ; fluctuation is not so evident. Temperature 100° F. The urine still contains a quantity of pus.

August 7th.—The patient remains in about the same condition. The bowels have acted twice after an enema. Her temperature remains at about 100° F. She complains of a sense of tightness across her abdomen. The swelling is not tender on pressure. Urine as before.

August 9th.—There was some pain about the umbilicus.

August 13th.—The patient has had some rigors. There is pain across the abdomen. The urine is less foul, and contains less pus.

August 19th.—Patient has had another rigor. The temperature remains high. The griping pain in the abdomen recurs from time to time. The bowels have acted this day rather freely after a dose of castor oil. The tumour has increased in size ; it is neither tense nor red.

August 21st.—There is a patch of dusky-coloured skin in the centre of the tumour.

August 22nd.—The tumour burst at this reddened spot this morning, while the patient was defæcating, blood-stained fœtid pus being discharged, and afterwards some fæcal matters escaped. This rupture was not associated with either pain or shock.

August 23rd.—Under chloroform, the opening was enlarged, and found to communicate with both the bladder and the cæcum ; a quantity of fæcal-smelling pus was evacuated.

The woman's condition fluctuated between this date and September 12th, when she died of gradual exhaustion.

The autopsy was made by Mr. Horsley, and the following is an abstract :—

The brain was rather wasted, but the membranes and vessels presented no special signs of disease. The muscular structure of the heart was rather soft—large vessels atheromatous. The lower lobes of the lungs were œdematous. In the left upper lobe there was a gangrenous patch close beneath the surface, breaking down and containing foul pus. The liver was fatty and friable. Spleen soft and small. The kidneys were very cirrhotic. In the fundus of the bladder there was a ragged, yellowish, friable, nodular growth, perforated in its centre by an orifice which led in-

directly into the floor of the wound in the abdominal wall. The rest of the bladder was slate-coloured, and showed evidence of chronic congestion. The anterior margin of the growth merged gradually into the mucous membrane, while the posterior margin was separated from the level of the surrounding mucous membrane abruptly. The abdomen when opened contained about four ounces of bile-stained pus, mainly in the right flank. The great omentum was drawn down to the back of the wound to which it was firmly adherent by old adhesions. The transverse colon thus formed a V-shaped loop with its apex just below the umbilicus. The bottom of the wound when laid open was found to lead by two sinuous openings into a ragged cavity, surrounded by very hard, yellowish, nodular masses of new growth. A coil of ileum was firmly adherent to the posterior surface of the wound, and to the ragged walls of this cavity. The sigmoid flexure (which was also adherent to this cavity) and descending colon were considerably distended with scybalæ. The left wall of the cavity formed the anterior wall of an abscess which lay along the line of the left external iliac vein, and contained yellowish pus, but not fæcal. On slitting up the intestines, the large intestine opposite the cavity was found to be firmly adherent to a new growth projecting beneath the mucous membrane, but not ulcerating. The small intestine was firmly attached to the new growth, mainly by its mesenteric border, and ulcerated almost completely through opposite the centre of the cavity.

Remarks.—The general appearance of the tumour on admission, led to the assumption that the case was one of incarcerated hernia, and, as may be seen from the notes, this proved to be partly the case. It is not easy to understand the production of the hernia, except on the assumption that the abscess had begun very chronically around adhesions formed between the growth and the abdominal wall, and that the bowel above the seat of disease had prolapsed into the cavity. The fact that the skin did not become reddened until three days before it burst is strongly in favour of the above explanation, and the temperature at the same time was about 102° F. Probably some of the bowel forming part of the contents of the hernia was already perforated, and certainly the cavity of the abscess was shut off from the general peritonæal cavity by firm adhesions soon after the taxis, on August 4th. At the *post-mortem* it was found that these adhesions were so numerous and involved such numerous and distant portions of bowel that enterectomy would have been impossible. The bladder, when examined on August 23rd, did not seem to be infiltrated with growth as turned out to be the case at the *post-mortem*, but the mucous membrane felt soft and spongy when pressed with the steel sound.

Water as a Diuretic.—Dr. Lauder Brunton (*Practitioner*, May), tells us that it is impossible to explain the elimination of water drunk by a healthy man, by a mere increase in blood pressure, whether general or local. It increases tissue change, but removes the waste products as soon as they are formed. In persons who are accustomed to take too little water, the products of tissue waste, may be formed faster than they are removed, and by accumulating, may lead to disease. Fatigue is to be regarded as the imperfect response of muscles and nerves to stimuli, and such an imperfection in their action may be due either to their imperfect nutrition, or to the imperfect removal of the products of their waste. There are many people who awake in the morning feeling languid and more tired than when they went to bed. Though such persons are often well fed and sleep soundly, and though they get better after walking about a little, yet Dr. Brunton thinks their languor depends on imperfect removal of waste products from the body, and has found that a tumbler of water taken just before going to bed, often prevents this languor.

Medical Times and Gazette.

SATURDAY, JUNE 14, 1884.

There are at present two Government Bills in which our profession is especially interested actually before the House of Commons, namely, the Medical Acts Amendment Bill, and the Burgh Police and Health (Scotland) Bill. The former of these two measures has been sent down from the House of Lords, has been read a first time in the Lower House, and rests at that stage. Whether it shall be advanced any further, and if so, how far, depends entirely upon the amount of real interest taken in it by the Government; and it must be admitted that, judging by past inaction and practical indifference on the part of both the Government and the House of Commons, it seems very probable the Bill will meet with the same fate as did its predecessor of last year.

The Burgh Police and Health (Scotland) Bill was read a second time on Monday last, and was referred to a Select Committee. The Bill, which consists of some 558 clauses, is very largely a measure of consolidation and amendment; but it contains a great number of sanitary clauses, and, amongst these, provisions for making the notification of cases of infectious diseases compulsory upon the medical attendant throughout Scotland. This principle has met with very marked opposition from the profession in England, but has never yet been seriously considered by Government, or by either the House of Lords or the House of Commons. It has, however, been directly condemned by the British Medical Association, and arrangements have been made by the Parliamentary Bills Committee of that body, and the Lord Advocate, who has charge of the Bill, for securing that the whole question shall be fully discussed before the Select Committee. The Association will thus render excellent service to the whole profession; and we may expect to obtain a well considered and weighty decision on a much vexed and vexing question.

Dr. Cameron has obtained a very good place on the business paper of the House of Commons, for July 1st, for bringing forward his motion respecting the outbreak of smallpox in the Metropolis. Meanwhile the Metropolitan Asylums Board are doing their best to meet the necessities of the epidemic. The general ambulance system which has been instituted has worked very well, and has no doubt materially helped to lessen the spread of the disease by providing for the removal of all cases to hospital immediately on notice by telephone or telegraph. Sir E. H. Currie, to whose energy, watchfulness, and admirable good sense in all these matters the public are greatly indebted, has brought forward a further improvement in the method of dealing with fresh cases. At present they are all, on removal from their homes, sent to a district asylum, and thence distributed according to the severity of the attack. Sir Edmund proposes that each district

medical officer shall, on notifying a case to be removed, state its character, so that mild cases may be taken straight to the ships, and the severe ones to the district asylum. This has been objected to, apparently on the ground that the responsibility of differentiating the cases ought not to be thrown upon the district medical officers; but the Board generally felt no doubt as to the competence of those officers, and the re-arrangement of the removal of patients was referred to the General Purposes Committee. The Board have received authority from the Local Government Board to acquire compulsorily, by purchase, lands required at Long Reach, for the acquisition of the Poplar District (Infectious Fevers) Hospital at Upton, and for the formation of a second camp at Darenth.

The Committee appointed to enquire into the operation of the Act for the appointment of a Director of Public Prosecutions have reported that the system has, after more than four years' trial, proved to be an utter failure. Of course they do not express their opinion of it with such brutal frankness as that; but they say that it "requires modification and development;" and then they recommend changes by which the existing system will be entirely swept away. The duties of the Public Prosecutor are to be transferred to the Solicitor to the Treasury, whose title will then be "Director of Public Prosecutions and Solicitor to the Treasury," and he will be the responsible head of a department divided into two distinct branches, each presided over by an assistant solicitor, the one dealing primarily with civil, the other with criminal business; and the Department is to practically conduct as well as to decide upon public prosecutions. The condemned system has certainly disappointed nearly every one, and been responsible for some ghastly failures of justice, while the proposed new system, if well carried out, can scarcely fail to be beneficial; and at the worst we may feel sure that, after the action lately taken by the College of Physicians and the College of Surgeons, we need not fear any repetition of such a public scandal as the Bower and Keates persecution. The Committee of enquiry have shown in their report great anxiety to prove that the system they recommend will cost a few thousand a year less than the old one. They felt no doubt, that such "a material economy" of the resources of this impoverished country would have more weight with the Government than could arguments as to mere increase of efficiency.

At the meeting of the Ophthalmological Society on the 5th of June, two papers, possessing more medical than surgical interest, were read. The first of these, by Drs. Sharkey and Lawford, referred to a case of acute myelitis, in which optic neuritis was an early and prominent symptom; indeed, it made its appearance before any of the symptoms due to the myelitis were complained of. Such cases as this are far from common, and so carefully recorded an instance must be regarded as a distinct gain to our knowledge of this as yet unexplained combination. Mr. Nettleship made an important communication on the subject of amaurosis in infants, but as he was not able to give the details of his cases, it is a little difficult to feel sure that they all belong to one category; undoubtedly some of them were cases of meningitis, a group of cases by no means unknown to those of large experience amongst children, recovery from which, as far as the sight is concerned, is, we should say, the rule when the patient is not left permanently hydrocephalic. But it is probable that all Mr. Nettleship's cases were not of this nature, as he spoke of permanent blindness resulting sometimes, which in our experience would but rarely occur from an uncomplicated basic meningitis.

The report of the Committee on Blindness from Ophthalmia Neonatorum, and the resolutions embodied in that report which were adopted at the same meeting, deserve and demand the most serious attention of all interested in the general well-being of humanity. One fact which we understand came to light in the enquiry, though it does not appear in the report, is the absolute certainty with which blindness from this cause can be prevented, if the treatment be only prompt enough. The representatives of the Obstetrical Society who joined this committee in their labours, ascertained from one of the Lying-in Institutions, that of the last fifty cases of this affection that had occurred in their practice, there was not a single instance of any other result than complete recovery. When we bear in mind that somewhere about 30 per cent. of all the blind in this country have lost their sight from this eminently curable affection, it must be admitted that a very strong case has been made out for the action of the Local Government Board, either in the manner indicated in the report, or by some similar process.

The final meeting of the Session of the Royal Medical and Chirurgical Society was held on Tuesday last, when no fewer than five papers were disposed of, leaving several others on the list, which will have to stand over until the next session. Mr. Arbuthnot Lane brought forward the subject of spinal curvatures, founded on a careful study of specimens in the Guy's Museum, as well as of others recently obtained from the dissecting-room. Then followed two papers, illustrating the subject of cerebral localisation: the first by Dr. Broadbent, on a particular form of amnesia—loss of nouns; the second by Dr. Sharkey (which unfortunately had to be read in abstract), on embolism of the right middle cerebral artery, producing left hemiplegia and hemianæsthesia, with death and autopsy seven years later. Both these papers were of great interest, but owing to the amount of work which had to be got through during the evening very little discussion took place, that which followed on Dr. Sharkey's paper being chiefly an amplification of details not contained in the abstract. Dr. Matthews Duncan then read a short paper on albuminuria with parametritis, the chief object of the author being to show the absence of this complication in perimetric inflammation, and in other abscesses. A brief paper by Dr. Stephen Mackenzie on the weight of the thyroid body in 84 persons dying from various causes, brought the evening's work to a close. The President, in adjourning the Society until

next October, said a few valedictory words, and hoped to meet the Fellows after the vacation in renewed health.

At the Epidemiological Society, on Wednesday, Dr. H. Franklin Parsons read a paper on the "Ætiology of Diphtheria," an abstract of which will be found in another column. As one of Her Majesty's Inspectors he has had many opportunities of enquiring into the origin and propagation of the disease, especially in rural districts, and his experience leads him to believe that direct personal intercourse in the school, the public-house parlour, and the field, plays a more important part than some are disposed to attribute to it. In this we agree with him, but we cannot say the same of the intimate relations which he, although cautiously, puts forward as subsisting between this disease and scarlatina. The fact is, he reposes far more reliance on the causes of death published by the Registrar-General, than we should, knowing how often certificates are filled in by medical men, at best perhaps by no means careful in diagnosis, on the evidence of a single visit or on the report of an unqualified assistant, and we must confess to having but little better an opinion of the crude mass of "facts" accumulated by the Collective Investigation Committee of the British Medical Association. The discussion carried on by Dr. Squire, Dr. Thorne Thorne, and one or two others, was poor. Dr. Thorne, however, in a few well chosen words, vindicated the independent and specific character of scarlatina, contrasting it with diphtheria, which he considered as still in a process of differentiation, and, like erysipelas and puerperal fever, not having acquired a definite individuality. Dr. Wortabet, of Beyrout, had sent a paper on the "Epidemic Diseases of Syria," but there was not time to read it. We shall revert to Dr. Parsons' excellent and judicial summary of all that is really known of diphtheria on a future occasion.

The series of conferences which are to be held at the Health Exhibition opened on Wednesday in last week, the first three, held under the auspices of the Mansion House Council, being very properly devoted to the subject of the season, the London poor and their dwellings. Mr. G. B. Longstaff read a most interesting and elaborate paper bristling with statistics on "The Population of London and its Migrations." He maintained that everything ought to be done to discourage immigration into large towns. A paper by Miss Gertrude Toynbee followed, containing a plea for making the dwellings of the poor more homelike; and another by the Rev. A. Mearns dealt with the physical and moral results of overcrowding. The first conference closed with one of the speakers suggesting that before the discussion was closed Lazarus should be given an opportunity of speaking on the subject as well as Dives. The chairman promised that Lazarus should be heard. The second conference, held on the 5th, began with papers by Mr. James Hole and Miss Lidgett, the former dealing with suburban dwellings and cheap railway fares, and the latter with the influence of ladies working amongst the poor. Mr. H. W. Harrod then read a paper, in which he proposed that 2,500,000*l.* should be raised as a building fund, half to be lent by the State at 3 or 3½ per cent. With this he calculated that provision could be made for nearly 50,000 persons, whose payments for rent would allow of a dividend of 4 per cent. being paid on almost the whole capital. The Archbishop of Canterbury, who presided at this conference, made an admirable speech, concluding with the self-evident but frequently ignored truth that the poor are of the same flesh and blood as ourselves.

At the third conference, held on Friday last and presided over by Cardinal Manning, Mr. Shirley Murphy read a paper on the difficulty of sanitary administration in the metropolis. The sanitary authorities, he said, as at present constituted, existed rather for the removal of nuisances than for the prevention of disease. Thus, there was no sanitary authority to deal with the size, ventilation, and arrangement of rooms in the construction of buildings, even when these were altogether unsuited for the requirements either of health or decency. It was only after the house was built, and the inhabitants had suffered ill-health or loss of life, that the State gave the sanitary authorities power to act. The reason why so little thought had been given to the health of London had arisen from the numerous difficulties connected with its government. At present no sanitary administration deserving the name could be said to exist in the greatest city in the world. The 39 local sanitary authorities had no jurisdiction over many subjects of vital importance to the public health, and the authorities upon whom these duties devolved were not primarily concerned in the prevention of disease. Mr. Murphy's thoughtful paper was followed by others of less importance, and by a speech from Dr. Alfred Carpenter, who urged the advisability of separating the repression of disease in London from the relief of destitution. The speech with which Cardinal Manning closed the conference was well-informed and statesmanlike — the more statesmanlike perhaps in making no attempt to be startlingly original. The fourth conference was held on Monday, under the auspices of the Society of Medical Officers of Health, the Sanitary Institute, and the Parkes Museum. A fairly full report of this meeting will be found in another column.

Wednesday's conference, held under the auspices of the same societies, was devoted to industrial diseases, and there was a large attendance of medical men to hear Dr. Bristowe's paper on that subject. Dr. Bristowe took the widest possible view of industrial diseases, gathering under that category such widely diverse affections as grocers' itch, wool-sorters' disease, clergyman's sore throat, and writers' cramp; besides, of course, the many forms of metallic poisoning, more commonly recognised as the penalties of unhealthy trades. He said at the outset of his paper that the investigation of the causes of disease was a subject which would ever engage the choicest intellects in the profession of medicine, and the character of the speakers who subsequently engaged in the discussion of the

paper went some way to support his contention. The Conference was followed by a sparkling lecture in praise of wine, by Dr. Thudichum.

We are glad to see that the Epidemiological Society is to hold a conference at the International Health Exhibition, on the afternoons of July 24th, July 25th, and July 26th, from 2 p.m to 5 p.m. The President, Dr. Norman Chevers, will open the conference with an address on Health in India, and the following subjects have been selected for discussion:—Prevention of Epidemics; Change in type of Epidemic Disease; Influence of Climate on Epidemic Disease; Behaviour of Typhus in England during the present Century. Papers must not occupy more than twenty minutes, and each speaker taking part in the discussions not more than ten minutes.

At the meeting of the Society for the Study and Cure of Inebriety, on Monday, Dr. W. B. Carpenter read a paper on the Ætiology of Inebriety. Every sensation, he said, must have a physical antecedent, and the mental craving for alcohol was the product of a physical condition. This was evidenced by the craving for a fresh dose of alcohol on recovering from the depression induced by preceding excessive doses, the mental condition being this expression of the physical condition. Another evidence was the development of the craving after excessive hæmorrhage, especially in the puerperal state. In such cases, the diseased condition having arisen from a temporary disturbance and not yet being permanent, a cure might be hoped for. The difference between temporary loss of nervous power and permanent depravation of nutrition of the nervous system was clearly seen in the results of treatment. Bodily fatigue was a frequent antecedent cause of inebriety, the diminution of heart power and the consequent depression often calling for alcohol or some other nervine stimulant. It was clear that alcoholic heredity might act as the antecedent physical cause, the alcohol habit in the parents depraving the parental nervous system and then similarly depraving the nervous system of the offspring. Nothing was so certain to induce the drink crave as the habitual use of alcohol by persons susceptible to its action, and when once the nervous system had taken on that depraved form this remained as a diseased condition. Alcohol was a powerful paralyser of the will, and whatever moralists might say, once the diseased condition of alcoholic inebriety had become confirmed moral means were apt to fail, and the diseased state must be recognised and treated. Such were some of the physical causes of inebriety. The moral causes were such as nervous shock and depression from loss of property or friends. The depression from the moral cause was physical, and developed a longing for a nervine stimulant. In the early stage of inebriety, a moral impression could be met and overcome by a moral impression, but in the confirmed stage of inebriety, where there was a permanent depravation of nervous nutrition, the treatment of the diseased physical state must be resorted to. The paper was followed by a brief discussion which was adjourned till Tuesday afternoon, July 1st.

A most successful meeting was held on Tuesday, at the Mansion House, with the view of securing public support for the foundation of a convalescent home hospital by the Home Hospitals Association. The successful career of Fitzroy House, and the cordial support it has received from the medical profession, warrant one in expecting a similar success for the new convalescent hospital, which is quite as much if not more wanted. Sir Risdon Bennett, in one of the best speeches delivered at the meeting, pointed out the two-fold danger of the present system of sending convalescents to seaside lodgings, which are often as harmful to the patient as the patient is harmful to them. Another important point suggested by Sir Risdon Bennett, was that there should be inland convalescent hospitals as well as seaside ones. The first requirement of a convalescent home for infectious cases is, that it should be far away from holiday haunts, so that the patients may be able to expose themselves the livelong day to air and sunlight without the likelihood of mixing with healthy people. Such a requirement is more likely to be found inland, within easy reach of London—a prime necessity—than at the seaside. The association should be strong enough to be able to disregard the popular tradition, which prescribes sea-air for the scarlet fever patient when convalescent with the same insistence that it once prescribed a pile of bedclothes for him when the rash was out.

Besides the International Medical Congress at Copenhagen in August, the International Congress for Hygiene and Demography will assemble for the fifth time, from the 21st to the 27th of the same month, at the Hague. Judging from the programme, which has been published at great length in the French Medical Journals, many papers of the highest interest are likely to be discussed, among them, one by Dr. Pasteur, on "The Attenuation of Virus; on "Temperature within the House," by M. Emile Trélat; on "Water Supply," by Dr. Crocq, of Brussels; and "Science the Enemy of Disease," by Professor Corfield. The first section will be devoted to general and international hygiene; the second, to that of towns and rural districts; the third, to personal, and the fourth to professional hygiene. Information may be obtained from Professor Overbeck de Meijer, of Utrecht, the general secretary.

For some months past, writes a Glasgow Correspondent, there have been lively meetings of the Fellows of the Faculty of Physicians and Surgeons, at which the scheme of amalgamation with the Edinburgh Colleges, and the granting along with them of a complete licence in medicine and surgery have been considered. The scheme submitted has been finally adopted by the colleges concerned, and comes into operation in October. The attempt to produce a combination of the Faculty with the Royal College of Surgeons, with the object of forming a Royal College of Surgeons of Scotland, of which the Fellowship should be obtained only by examination, has not been successful. At the last monthly meeting of the Faculty it was announced that the negotiations had been broken off because the

representatives of the Edinburgh College insisted upon all the examinations being held in Edinburgh. The Faculty have now to consider the nature of the examination to be instituted for the Fellowship, of which the syllabus was submitted five months ago. Very little progress has been made towards the adoption of the various clauses, the principal ground of opposition being the too severe character of the examination. It is said that there is a probability of the scheme being sent back to the Council for further consideration.

The spirit of reform seems to be still rampant at the Glasgow Royal Infirmary. It is only five months since the rules and regulations "as revised by the managers," regarding the administration of anæsthetics, were issued to the members of the staff. It might have been supposed by anyone not acquainted with this hospital and its management, that a period of rest would follow. But since this time, as we have already announced, the number of physicians has been reduced from five to four, and a surgeon has been appointed to take charge of the Burn, Erysipelas, and Lock Wards. As compensation for the disagreeable and dangerous cases to which he must attend, the managers have attached a "salary," or honorarium, to the position, the amount being one half of that received by the other surgeons! Further changes are threatened, for having reformed the House Staff, the managers are considering the question of dispensary organization. In the midst of all this work it must be unsatisfactory to the managers to feel that the older members of the Hospital Staff are tiring of this incessant change and worry. At the quarterly meeting in August, a surgeon and a physician have to be elected to take the place of Dr. James Morton and Dr. J. D. Maclaren. The former's term of office expires: the latter does not seek re-election. There will be many candidates for both vacancies, and canvassing has already begun.

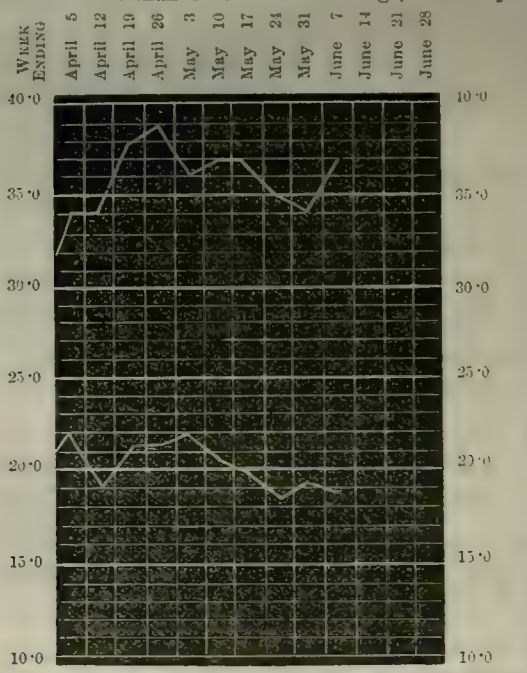
The important post of Secretary to Council in the Royal College of Surgeons in Ireland, vacant through the death of Dr. James Stannus Hughes, has been filled by the appointment of Dr. Archibald H. Jacob, whose ripe experience, unquestioned ability, and literary talent cannot fail to justify the choice of the members of Council who voted for him. Dr. Jacob's appointment will leave a seat vacant on the Council, and there can be little doubt that it will be filled by the election of Dr. Rawdon Macnamara, who obtained the next largest number of votes to those secured by the last on the list of successful candidates for the office of Councillor at the annual election, which took place on the first Monday in June. Should Dr. Macnamara be selected at the forthcoming election to fill the vacant seat upon the Council, the awkward *contretemps*, by which the representative of the College upon the General Medical Council ceased to be a member of the Governing Body of the College, will be satisfactorily set at rest.

The death of Dr. James Stannus Hughes may possibly lead to an amalgamation of the School of Surgery of the Royal College of Surgeons in Ireland with the Carmichael College of Medicine, Dublin. One of the chief stumbling-blocks hitherto in the way of this much-to-be-desired result was the fact that the chair of Surgery in both Schools was divided. In the School of Surgery, Dr. Hughes and Mr. William Stokes were Joint-Professors of Surgery. In the Carmichael College the duties of the corresponding chair were discharged by Dr. John Kellock Barton and Dr. A. H. Corley. It so happens that Dr. Barton's resignation as a Lecturer was handed in shortly before Dr. Hughes's death, so that in the event of Dr. Corley's coming forward and being elected as Professor Stokes's colleague, all difficulty would be removed as to the amalgamation of the Surgical Chair, one of the most important in the two Schools. If the union between these important Schools should become *un fait accompli*, the benefit to the Dublin School will be inestimable.

The action of the two Dublin Colleges with respect to the Medical Acts Amendment Bill is significant in point of contrast. The Royal College of Surgeons, at the statutory annual meeting of the Fellows, held on the Saturday preceding the first Monday in June, took up a position of uncompromising hostility to the Bill as at present framed. At that meeting the following resolution was adopted:—"That this College thoroughly disapproves of the proposed Medical Bill as it now stands before Parliament, and hereby recommends its incoming Council to oppose it by every constitutional means at their command, unless its provisions be amended in such a manner as the Council may consider to maintain the interest of the College." The King and Queen's College of Physicians, on the contrary, have petitioned the House of Commons to amend the Bill in certain important particulars. Of these the first is the question of representation on the Medical Board of Ireland. As the Bill now stands, Clause 9 proposes to grant *four* representatives on the Board to each of the Universities—the University of Dublin and the Royal University of Ireland, and only *three* representatives to each of the Corporations, the King and Queen's College of Physicians and the Royal College of Surgeons. The Colleges are by this arrangement hopelessly out-numbered, and are in danger of losing any representation whatever on the new Medical Council. Consequently, the College of Physicians have put forward a powerfully-worded and weighty line of argument in favour of an equality of representation on the Board. Other amendments proposed by the College of Physicians are:—(1) The transference of the framing of examination rules from the Medical Boards to the Medical Council; (2) The disposal of the Surplus Funds of the Medical Boards so as to secure the maintenance of the Corporations in full efficiency; and (3) A modification of the privileges proposed to be accorded to undergraduate candidates for the final examinations under the Bill. We cannot help thinking that in this instance the policy of the College of Physicians is wiser than that of the sister College.

If the number of deaths from zymotic diseases in London last week had kept to the ten years' average instead of being 55 above it, the general death-rate

would not have been more than 17·2. As it is, it was 18·9, the total number of deaths being 14 below the average. As the deaths from respiratory diseases were only 5 below the average, there must have been a considerable deficiency of deaths under other headings to counterbalance the excess of 55 caused by zymotic diseases. On looking through the tables it will be found that this deficiency is in great part furnished under the heading of "old age," which was certified as causing only 15 deaths as compared with an average of 45·5. Considering that the mean temperature of the week was more than 5° below the average, this escape



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the first ten weeks of the present quarter.

of old age is a little remarkable. Of the zymotic disease small-pox, measles, and whooping-cough were the most fatal, causing between them 213 deaths, or nearly three-fourths of the whole zymotic mortality. In the 28 great English towns, last week's death-rate was 19·6 per 1,000; while in the eight great Scotch towns it was 23·3 per 1,000. The zymotic death-rate in the former was 3·0, and in the latter 4·3.

By the Army Circular of May 1st, 1884, the War Office Authorities sanction the formation of ambulance classes for ambulance drill and instruction in first aid to the wounded, throughout the whole Army, Regular, Militia and Volunteer. The training of officers and men is to be carried out under orders of general officers commanding and principal medical officers of districts. Commanding officers are to afford medical officers undertaking the duty every facility for the formation and instruction of classes, and are to detail a competent non-commissioned officer to assist the medical officer in the drill, and to take charge of equipment and appliances. Details are given as to the number of drills and the inspection of the classes when instructed. Certificates of proficiency will be given only to Militia and Volunteer corps in which two men of the rank and file per company are told off as recognized stretcher bearers of the corps who will, as now, wear the Geneva badge on the right arm. But to secure efficiency and the retention of the right to wear the badge, the recognized stretcher bearers must attend four drills annually.

It is interesting to observe that the authorities look upon the ambulance movement with so much favour as to extend its instruction to the Regular Army and Militia. Originating among the Volunteers, thanks to the untiring energy of Lieutenant Maclure of the London Scottish, the ambulance drills are being generally adopted by most Volunteer surgeons in their respective corps, and their bearer companies are now recognized as a regular part of their regiments. A further development of the movement is the formation of the Volunteer Medical Association which will, if accepted by the War Office, represent the Army Medical Staff of the Volunteers. With respect to this last, its claims for recognition are under the consideration of the authorities, and it promises, if accepted, to render the Volunteer Army complete in its medical arrangements, leaving the Commissariat and Transport still unknown.

Volunteer Medical Officers have now a recognized position in their regiments and definite duties and drills to superintend and men to command and it is to be hoped that they will now accept their position with favour and drill their men in ambulance and stretcher work, thus taking their place among their working brother officers instead of being, as is the case in many regiments, merely ornamental appendages. In several metropolitan and provincial Volunteer regiments, the bearers are intelligent, well instructed and well drilled and considering their few opportunities for practical work they are wonderfully efficient and in all cases are zealous in their duties. We look upon this military ambulance work as a great advance and we trust that the Medical Officers of our Volunteer army will not neglect their opportunity.

It is stated that M. Parize, a French *savant*, has discovered swarms of bacteria in the very centre of a common house-brick. These all-pervading creatures had already been found in plaster walls and in wood floors, and doubtless before long they will be sought for and perhaps discovered in iron rails, iron not being, so far as we know, a disinfectant in its uncombined state.

Professor Gosselin, the acknowledged head of French surgery, since the death of Nélaton, has, by reason of advancing years and impaired health, found it necessary to resign his chair in the Paris Faculty, the labour of teaching and especially of examining, which is carried on on so large a scale at Paris, proving too severe a tax upon him.

The Committee of the Bower and Keates' Fund met at Sir William Jenner's residence on May the 30th.

It was reported that the second civil action had been decided in favour of the defendants,—the jury being so strongly of opinion that there was no case against Messrs. Bower and Keates that they did not desire to hear the witnesses for the defence; that notwithstanding this, Messrs. Bower and Keates' Solicitor had been served with notice of motion for a new trial, on the grounds of "non reception of material evidence, misdirection," &c. The Secretaries read a letter from Dr. Bower giving a detailed statement of the expenses that had been incurred in the defence, amounting to 1,006*l.*, and the Committee unanimously agreed to pay over on account 750*l.* out of the fund towards meeting the expenses.

We see in the papers an announcement of a *Matinée* at the Royal Avenue Theatre on Thursday, June 26th, at 2.30 p.m., in aid of the funds of the East London Hospital for Children. Besides its good object of giving much-wanted help to the Charity, this undertaking has a special interest of its own, the play that is to be performed being written, we understand, by a London doctor, and founded upon incidents of hospital life, with which he is intimately acquainted. "Sister Grace," the title *rôle* in this new and original drama, will be played by a well-known actress, who will be supported by a company of considerable strength. It is much to be hoped that the double interest in this entertainment will ensure a full house. Tickets can be procured, and any enquiries made for seats, &c., at the Theatre; and also of Mr. J. Scott Battams, the Resident Medical Officer at the Hospital, Shadwell.

A serious epidemic of typhoid fever has broken out at St. Albans, and the Local Government Board have commissioned Mr. Shirley Murphy, Medical Officer of Health for St. Pancras, to act for them in the investigation of the outbreak. More than 100 cases have already occurred, and Mr. R. C. Lloyd, one of the principal medical practitioners of the neighbourhood, has fallen a victim to the disease. The fever is believed to have been spread through the agency of milk.

It is reported from Cairo that the regretable dispute which has arisen in Egypt between Sir Benson Maxwell and Dr. Crookshank, of the Egyptian Prisons' Department, is likely to terminate in favour of the latter. Sir Benson Maxwell's interference with the Prisons' department has been reprobated by his superior officer, and he has been warned that his threats to prosecute Dr. Crookshank must cease.

The usual annual report made by the Home Office under the Vivisection Act, has just been issued. It states that during the year 1883, 44 persons held licences; and of these 32 performed experiments and 12 performed none. The total number of experiments of all kinds during the year was about 535. Of these, 256 were done under the restrictions of the licence alone; 55 without anæsthetics; 122 under certificates dispensing with the obligation to kill. Four or five experiments on dogs and cats were performed. The writer of the report is at great pains to prove that the suffering inflicted on animals under the Act was wholly insignificant. What he does not say is, that so long as the restrictions of the Act are maintained, it may be expected that the advance made in England in the direction of relieving human and animal suffering will be equally insignificant, compared with what it otherwise might be.

The following are candidates for the Council of the College of Surgeons at the Election in July next:—Mr. Thomas Smith (re-election), Mr. Lawson, Mr. Durham, Mr. Cowell, Mr. Pemberton, Mr. Berkeley Hill, Mr. Barwell, Mr. Allingham, and Mr. Gant. There are five vacancies, and we should like to see the first five candidates we have named successful. Mr. Berkeley Hill has, no doubt, a strong claim, but the Medical School to which he belongs is already fully represented on the Council.

BREAKING-UP.

With this week the academical year in that University of advanced medical teaching, constituted by our various societies, comes practically to a close, and the students will have a time for leisure and thought, before joining in those holiday exercises and contests in Belfast, Copenhagen and Montreal, to which many of them will no doubt be drawn. They have had a very useful and industrious session, the classes have been well attended, and the general progress has been satisfactory. It is true that there has not been any set disputation which can rival in magnitude or importance the debate on syphilis at the Pathological Society a few years ago, or that on diphtheria and croup at the Royal Medical and Chirurgical Society more recently; but it is very questionable whether these academical discussions do so much to extend or to crystallize knowledge, as might be at first sight expected of them. At any rate it will be generally admitted that it would be unwise of our advanced students to allow themselves to be too often tempted away from their ordinary unobtrusive labours to take part in these grand sham-fights. The past session, nevertheless, has witnessed some debates of decided interest. Surgeon-General Hunter's paper, on the "Outbreak of Cholera in Egypt," was followed by a discussion, which, from the number and experience of the speakers, must be admitted to be of value and importance. It is difficult to say that any definite advance has been made in our knowledge by it at present, as such diametrically opposed views were expressed on the mode of propagation of the disease, but independence of thought is always healthy, especially when preceded by and based upon a practical acquaintance with the subject. If Koch be right, then Sir Guyer Hunter and the large number of Indian doctors who think with him—and they include some of the ablest men in the service—have been working on the wrong tack, for according to present beliefs, insanitary conditions alone will not suffice for the production or evolution of a specific organism. The discussion on the cold water treatment of typhoid fever, at the Medical Society, brought out forcibly the proverbial differing of doctors, and showed once more how difficult and dangerous a thing it is to handle statistics. The evidence was not on the whole

strong enough to encourage the use of the bath as a routine treatment. Pneumonia formed the subject of debates at Liverpool and Birmingham, with especial reference to its ætiology, and its infectious character. The Irish Academy of Medicine, in their Surgical Section, discussed the radical cure of hernia at some length, and the same subject was also debated at Liverpool, the majority of speakers in both cases being distinctly in favour of operative interference of some sort or other. More recently the Glasgow Pathological and Clinical Society have discussed albuminuria in all its bearings, chemical, pathological and clinical.

Amongst the dissertations on surgical subjects, those on the treatment of fractured patella, by Sir Joseph Lister, at the Medical Society, and by Messrs. Heath and G. R. Turner, at the Clinical Society, are to be noted. It is clear, from these papers and from the remarks made upon them, that much better results are looked for and obtained than was the case ten years ago. Mr. Hutchinson departed somewhat from the beaten track in advising high amputation for gangrene, and Mr. Clutton added another to the list of triumphs of abdominal surgery, in his successful case of intestinal obstruction due to a diverticulum. Mr. Lawson Tait's communication on hydro- and pyo-salpinx to the Obstetrical Society, on which a dropping fire of discussion is still being kept up in these columns, deserves mention, as well as Dr. Fowler's paper on the same subject from a pathological standpoint, communicated to the Medical Society. At this Society too was read Sir Andrew Clark's paper on catheter fever, by which he incurred the opposition and criticism of nearly all the leading surgeons of London. The subject has since been under consideration at Glasgow, where, if we remember rightly, it met with a more favourable reception.

Turning next to medicine, it seems almost unnecessary to say that the Clinical Society have had an evening at myxœdema, for this is now an annual occurrence with them. Diseases of the nervous system always claim a large share of the time of our student teachers, and in this respect the past session has not differed from its predecessors. Dr. Ferrier, as Marshall Hall prizeman, gave an account of recent work in neurology at the Royal Medical and Chirurgical Society. Amongst the other communications on this subject, we may refer to Dr. Bastian's cases of hæmorrhage into the brain, and Dr. Althaus' case of syphilitic tumour of the meninges, both read before the Clinical Society, to Dr. Pye-Smith's case of tumour of the optic thalamus at the Pathological Society, to a paper by Dr. Sharkey on homonymous hemianopia at the Ophthalmological Society, and to a paper by Dr. Gowers on spasm of the ocular muscles, at the same Society. To these we must add the paper by Mr. Durham on trephining the lower jaw for neuralgia, and one by Mr. Chavasse on neurectomy of the second division of the fifth nerve for the same complaint.

Diseases of the circulatory system have been illustrated by Dr. Samuel West's papers on "Purulent Pericarditis," and the "Circulation through the Coronary Arteries," at the Pathological Society, and by papers on arteritis, by Dr. Hadden and Mr. Gould, at the Clinical Society; while aneurysms have received a fair amount of attention through papers by Mr. R. W. Parker, at the Royal Medical and Chirurgical Society, and by Drs. Turner and Kidd, at the Pathological Society. A paper on the "Ætiology of Tuberculosis," by Dr. Dawson Williams, at one of the earlier meetings of the Pathological Society, afforded Dr. Wilson Fox the opportunity of renouncing his former views, and of expressing his acceptance of the proposition that tubercle can only be set up by tubercle. Some interesting examples of tubercular disease of the tongue were shown by Messrs. Barker and Godlee, at successive meetings of the same Society. In conclusion, we ought not to omit mention of the valuable papers on bone disease in wild animals which Mr. J. B. Sutton has contributed to the Pathological Society from time to time, as the result of his unrivalled field of observation at the Zoological Society's Gardens.

All these exercises will have prepared our students, both young and old, and kept them in good fettle for the grand international contest at Copenhagen. There they will meet friendly antagonists trained in the studies and laboratories of Germany (with the help of methods which we in England have had to renounce) to a super-subtle refinement of intellect which they cannot hope to rival; they will have to match their powers of clinical insight with that lucid and logical form of mind which can see, or feign to see, order in every chaos. But though they have brought to their work less industry perhaps than the German, and less clearness of thought than the Gaul, we may be sure that they will fully maintain in the contest that reputation for robust common sense, which has always distinguished the British School of Medicine.

MILK *VERSUS* MEAT IN THE NURSERY.

Milk is, doubtless, of all articles of diet the most valuable and the most abused—abused, that is, in the sense of being violated as to quality. For all practical purposes the milk-supply of our own, as of most civilized countries, is derived exclusively from the cow; for the well-meant efforts of the British Goat Society have not yet attained that measure of success which they deserve, and which would justify us in reckoning goat's milk as a common article of consumption amongst that large class to whom the "poor man's cow" is unfortunately an unknown or an unappreciated blessing. The true story of the treatment and distribution of our milk is a strange and a somewhat disheartening one. In itself a nutritious, satisfying, all-sufficing food, milk is at once the hope and the despair of the modern food reformer. The inhabitants of large cities must not expect to obtain it both good and cheap; they are fortunate if it can be bought pure, fresh, and at a reasonable rate. On the other hand, there are large "country districts" in England where milk is rarely or never drunk by the peasant classes. These anomalies and disappointments are dependent on the source whence the milk is derived, as well as on the vicissitudes to which it is subjected in virtue of its position as a perishable article of commerce. Its natural quality and composition differ considerably according to the breed of the animal which yields it; and if the public, or individuals, prefer and demand milk of a particular appearance, the dairyman

or the purveyor is tempted to secure this by artificial means: and in such a case adulteration may be said to be initiated and fostered by the caprice, or ignorance, or want of reasonableness of the consumer.

Normal physiological processes in the cow produce corresponding changes in the mammary secretion. For some days after calving the milk acts as a drastic purgative upon the young child, as on the calf; and every two or three weeks, at the periods of recurrent œstral excitement, the milk is distinctly affected in character for a few days, after which it is again furnished of its usual quality, but in somewhat lessened quantity. And although the average quality of the daily yield of a large herd of cows may vary but slightly, it must be remembered that the milk of but two or three animals goes into each can, and that it is exceptional for the whole milking from all of them to be mixed together before it is placed in the cans and sent out for distribution. The quality and kind of food supplied to the animal produce effects which are often sufficiently noticeable in the taste and appearance of the milk and the butter. Brewers' grains, which are largely used by cow-keepers—especially by those in towns—increase the yield of milk, but make it thin and white. Some years ago a cow-keeper in a university town stated that he had given up the use of grains because, although they greatly increased the flow of milk, yet when his cows were fed on good hay and roots the milk not only kept better, but would "carry more than twice as much water." General disease, bad condition, and local disease and injuries of the udder are other important factors in determining the quality of the milk produced. But supposing the animal to be in perfect health and condition, and that every precaution has been used to ensure cleanliness during the milking, several other conditions must be observed if the consumer is to obtain the best possible value for his money. Not the least important of these is the maintenance of a proper temperature.

When drawn from the udder, milk has a temperature of about 100° F.; that most conducive to its preservation in good condition is about 50° F. A higher temperature, as that of the air in warm summer weather, or a colder, as during the frosts of winter—but especially sudden and repeated variations—are prejudicial. It is obvious that this implies elaborate and intelligently supervised arrangements for iceing or for heating during transit, to which most of the railway-borne milk, contracted for from small and scattered country farms, is not, and cannot be subjected. It is of course equally necessary that "churning" be prevented during the journey, and this is obviated by filling each can quite full up to the bung or stopper. Another essential of good milk is a rapid and regular distribution of the supply. Under favourable circumstances, milk will doubtless keep "fresh" for a period of seventy hours, or even longer; but it is not benefited by the process, and there can be little doubt that its deterioration has been in progress for some time before it turns distinctly sour. But if the evening's milking is kept until early morning before starting on a long railway journey to the city—a journey performed without any special precaution for regularly maintaining a favourable temperature—the limit of its endurance will have been well-nigh reached by the time it is delivered to the consumer on the morning of the following day; and this result will not be affected by the fact of its having been mixed by the city milkman with some portion of later arrival than itself. It is the custom in some dairies in large towns, to add a small quantity of borax to the milk which they receive; this serves to increase its keeping qualities, and appears to be in no degree harmful; it may easily be imitated by the country housekeeper with decided advantage in hot weather.

Seeing, then, the difficulties which attend, and the precautions which must be taken to ensure an initial supply of pure milk of good quality—having regard to the actual cost of its production, and to the difficulties which attend its collection, storage, transit and distribution in good condition; and allowing a minimum profit to the farmer, to the contractor, and to the retailer,—it is clear that good pure milk, although always a cheap food, can never be an inexpensive article of diet. In other words, what is true of other things is equally true of milk—if it is to be genuine and of first-rate quality, a fair price will have to be paid for it.

That, in this case especially, it is real economy to pay a good price for good value, will not be denied; it is only a matter of regret that the consumption of milk amongst our juvenile population is not greater than it is, and that its purchase is not always regulated by the principle which we have thought well to emphasize. The value of milk *versus* meat, as the staple of young children's food, is strikingly brought out on perusing some statistics lately published by the authorities of the Orphan's Home and Asylum, in New York. Children are admitted from three to eight years of age, and are kept in the institution until twelve years old. The dietary for children under eight years of age, comprises milk and cereals, with vegetables and fruit in suitably varied combinations, but meat and fish are both rigidly excluded. Children over eight years old have meat three or four times a week with their dinner, and at those meals milk is omitted. Under these conditions, the record for the past twenty-five years shows a remarkably low death-rate and an unusual freedom from disease of all kinds. These happy results are doubtless due in large measure to the superior sanitary arrangements adopted there; but the noticeably small number of cases of gastro-intestinal derangements which are recorded year by year, can only be explained in reference to the admirably devised bill of fare—plain, nutritious, bountiful, and yet unstimulating—which is so well adapted to the age and wants of the inmates. The year 1865 was the only one during which the children under eight had a meat diet; and in that year—the total number of inmates being 139—it is significant that there occurred 98 cases of gastric disorder (as against 25 only in the previous year with 124 inmates), and a total of five deaths, this number being exactly *one-fourth* of the total deaths recorded during the whole of the 25 years, 1859–82. In comparing the case of such children with that of others, it must not be forgotten that the majority of them are the descendants of those whose condition in life was so unfavourable to health,

that they are placed in the Home "already impregnated with the seeds of disease, sown by vice and violation of all sanitary laws." Such a diet cannot but be serviceable to the children of the present age, when adult life is carried on at high pressure, and disturbances of the nervous system are so rife. Not a few men and women may be said to owe their good health and success in life—if not life itself—to such a factor in the regimen of their early years. There is one more point which is too easily ignored to allow of its being passed over in silence. Unfortunate as the inmates of such an Orphan's Home may be in the loss of parental love and care, they are happy in being spared the ingestion of unwholesome and (for their age) indigestible food; and, without being cynical, we may say that, for the child of tender age, there is an inestimable advantage in the absence of the "indulgent parent" who would thoughtlessly tempt it with morsels of meat and other dainties quite unsuited to the capabilities of a digestive system which is still in the earlier stages of its physiological development. Such unkind petting is far too common amongst nurses as well as parents; but the tit-bit from Mamma's plate deserves a condemnation as severe as the anathemas which are justly launched against the "sip from Papa's glass." Such acts have no true kindness in them: they may afford a selfish indulgence to a thoughtless parent, but for the child they are cruelty, or worse.

CLINICAL PAPERS.

No. XII.—The Radical Cure of Hernia.

Within the whole range of operative surgery no more striking instance of return to ancient procedure is offered, than in the case of recent attempts to obtain the radical cure of hernia. The practice followed by the "Rupture Cutters" of the Middle Ages of removal of the entire hernial sac, has in a modified form under the influences of modern experience and antiseptic methods, regained the foremost place as the best operation in cases in which a radical cure is contemplated.

The following paper will deal briefly with the principle of, the different methods of performing, and the indications for, the operation; also with the immediate and ultimate prognosis in cases in which it has been performed.

The principle of the modern operation is a combination of those on which two of the older methods were based, viz., the obliteration of the sac, and efficient closure of the neck by the firm organisation of inflammatory products deposited as a result of the operation. The aid of a plug of pre-existing connective tissue, an important element in the methods of Wood and Wützer, is entirely dispensed with.

For the sake of simplicity the modes of operation may be placed under the following two heads.

1. Dissection out of the entire sac, with ligature of the neck.

2. Dissection out of the entire sac, and suture of the margins of the ring.

One of these two plans, with some modifications not worthy of consideration as distinct operations, is suitable for every case of rupture, and we will at once proceed to the consideration of their adaptation to the special forms.

The first method may be employed for the cure of any variety of hernia, but in inguinal and umbilical or ventral herniæ, where a definite fibrous ring exists, the margins of which are capable of approximation, the addition of sutures carried across this ring, as laid down in the second method, is always to be recommended.

In inguinal hernia the sac is exposed and laid open, existing adhesions are freed, and the contents are returned, or in the case of omentum usually removed, as in an ordinary case of kelotomy. The entire sac is then freed from its connections and removed, care being taken to cut through the neck at its extreme limit above, to ensure which, in ruptures that have only been recently developed, it may be advisable to lay open the still existing inguinal canal. This thorough removal of the neck of the sac is a most important point in regard to possible future re-development of the hernia; recurrence being the more likely, should a depression be left at the site of the old opening as a determining starting-point. Where the sac is of very large size or of the pre-peritonæal variety, the removal of an inch or more of the neck may be advantageously substituted for complete extirpation, since the latter often involves a considerable amount of immediate and some danger of recurrent hæmorrhage from the scrotal vessels, and in the case of a pre-peritonæal sac, dangerous interference with the peritonæum. When the sac is left, it should be drained from end to end to ensure its granulating up from the bottom. The sac or its neck having been removed, sutures are carried across the ring and its edges drawn together; they should have a firm hold, but care must be taken to avoid the epigastric artery. The stitches should be of silk or stout catgut cut short, and although their permanent efficacy is doubtful, they are unquestionably of immediate use if the patient has a cough, and of ultimate benefit as a means of provoking the deposition of a sufficient amount of inflammatory products in the neighbourhood of the ring, the all-important factor in the process of cure which antiseptic precautions rather tend to prevent than to favour. In this variety also arises the question of removal of the testis under certain conditions, *e.g.*, its situation in the inguinal canal, or an extremely intimate connection between the neck of the sac and the elements of the spermatic cord. In the former case, we are mainly influenced by the state of development of the organ: if it appear atrophied and useless, it should be removed, but if it be of fair size it, together with the cord, should be freed and lowered into the scrotum, so as not to interfere with the subsequent application of a truss. In the second case, where the sac has been forced down among the elements of the cord, some of these have in recorded cases been unavoidably divided, with the result of atrophy or gangrene of the organ; hence, if the *vas deferens*, or the spermatic vessels, have been accidentally cut during the operation, the testicle should be removed.

In crural or obturator hernia, the surroundings of the ring preclude the use of sutures; and here we must content ourselves with the first method, the neck either being ligatured *en masse*, or, preferably, in two halves. The sac should be drawn upon so as to ensure a high division of the neck, and then the latter is transfixed with a doubly armed aneurysm needle. The ligatures are tied on each side and the sac removed. This proceeding very materially diminishes the size of the crural opening, and yet allows temporary drainage from the peritonæal cavity, in many cases a decided advantage. The close proximity of the femoral vein has not in any recorded case given rise to trouble.

As to the propriety of employing drainage, in all cases where there is ascites, or where the state of the bowel is doubtful, a tube should be left so inserted as to drain the abdominal cavity; usually the tube should reach up to the ring only.

In considering the indications for the operation, a distinction must be made between strangulated and non-strangulated ruptures. Of the former, it may shortly be said that every case is suitable for the operation in which the patient and the strangulated bowel are in fair condition. The objections as to the enforced prolongation of the herniotomy, and the danger of cooling down a peritonæal surface, are, in ordinary cases, more than sufficiently counterbalanced by the advantages gained. The only contra-indications are such feebleness of the patient that the least prolongation of the operation might be fatal, or such a condition of bowel as to lead one to suppose the supervention of gangrene probable.

In the choice of cases of non-strangulated hernia, the exercise of a far greater amount of discretion is demanded, since here the operation is one of expediency, a serious one *per se*, in place of being a mere technical detail slightly lengthening an ordinary herniotomy. The principal points to be taken into consideration are the following :—

1. The age of the patient. As will be seen below, the operation should not be undertaken at either of the extremes of life. At both there is extreme difficulty in keeping the wound aseptic; old people are very liable to lung complication accompanied by cough, while in children it is difficult to ensure the necessary quiet.

2. The general health, as in the case of all operations of expediency, must be carefully gone into; a tendency to cough is naturally unfavourable.

3. The nature of the hernia. Many ruptures owe their origin to some radical defect in the conformation of the patient; as, for instance, general weakness of the abdominal walls, especially in the neighbourhood of the usual hernial openings, an excess of subperitonæal tissue with loosely attached or distensible parietal peritonæum, and perhaps abnormally long mesentery. Information on these points should be sought in careful examination of the patient, and enquiry as to the rapidity of development of the hernia, and evidence of such defects should carry considerable negative weight when the question of operation arises. Congenital herniæ, on the other hand, being unlikely to depend on any of these weaknesses of conformation, but simply arising from accidental patency of the inguinal canal, are *cæteris paribus* favourable cases for operative intervention.

The above points having been determined, the indications for operation are shortly :—(1) Excessive size, the hernia being beyond the control of a truss, and interfering materially with the patient's avocation; (2) Large size, with irreducibility, since if the operation accomplish nothing further, the hernia may at least be converted into a reducible one; (3) Irreducibility with troublesome intestinal symptoms, such as the vomiting sometimes observed in irreducible omental hernia; (4) Rupture in young patients, in whom its existence interferes with entrance into one of the public services, or into a public institution. Much care is necessary in the choice of cases coming under this heading, the state of the general health and the disposition being important considerations. The operation should not be performed on children below six years of age.

Lastly, as to the immediate and ultimate prognosis; here, as in the matter of indications, a hard-and-fast line must be drawn between cases of strangulated and non-strangulated hernia. The results quoted are derived from the statistics of Leisrink. The cases are of mixed nationality, but the results seem very much in accord with those observed by the writer of this article in a limited number of cases operated on in a London hospital.

First, as to strangulated hernia, Leisrink has collected 188 cases with 33 deaths, a percentage mortality of $17\frac{4}{3}$, which compares very favourably with that obtained in simple herniotomy. Recurrence is stated to have occurred in fifteen instances ($8\frac{1}{5}$ per cent.), and in 51 cases ($27\frac{7}{5}$ per cent.) no information was to hand on this point. These numbers appear to prove that the radical cure procedure in no way increases the danger of herniotomy; while, on the other hand, the necessity of opening the sac in all cases, entirely abolishing the dangers of "reduction *en masse*," or the reposition of strangulated or gangrenous gut—accidents occasionally met with in the days of extra-peritonæal operation—together with the disposition to early operation engendered by the advantages to be gained, would seem likely to still further improve its results.

Secondly, as to the results in non-strangulated hernia. Leisrink has collected 202 cases with fifteen deaths ($7\frac{2}{5}$ per cent.) In a smaller series of cases, not included in the above number, communicated to Leisrink by Dr. Benno Schmidt, we have 55 cases with 11 deaths (20 per cent.)

In cases coming into this category, we tread on new ground, since a radical cure, being the whole object of the operation, and not a secondary advantage gained in addition to the relief of strangulation, recurrence means absolute failure, and death, the loss of a patient who might otherwise have lived an indefinite period. It is, therefore, needful to carefully note the cause of death in Leisrink's cases. (In Benno Schmidt's we have no details.) Nine cases ($4\frac{1}{3}$ per cent.) of the whole number died from septic infection, a source of danger which should theoretically be *nil*, and in any case the percentage is too high. Of the remaining six, two died of embolism, one cerebral, the other pulmonary; one from an intercurrent attack of pneumonia eighteen days after the operation, and when the wound was

healed; and two others from internal hæmorrhage. Of these six deaths little can be said, as, with the exception of the two cases of hæmorrhage, the causes were such as may follow any operation of expediency. The two cases of hæmorrhage point to the necessity of care in the arrest of bleeding from the scrotal vessels (the writer of this article has known a case in which death occurred from the same cause, the blood flowing into the peritonæal cavity and into the large antiseptic dressing); and they considerably strengthen the reasons for excising the neck only rather than the whole sac in large herniæ. The non-occurrence of peritonitis is a striking fact, it is only noted three times in the whole number of cases. The percentage mortality may also be lowered to 5·9 by the elimination of cases below ten and above sixty years of age, an argument for the exclusion of cases beyond those limits.

Then, as to the question of recurrence. The total percentage reaches $33\frac{1}{3}$; for inguinal hernia $32\frac{1}{3}$, for crural 38, for umbilical and ventral $37\frac{1}{2}$. These numbers seem to correspond as to relative success in the different varieties with what has been observed in London hospitals; the only debatable point is the relative success in inguinal and crural herniæ, while the success in cases of umbilical hernia is striking when the high mortality of operations on strangulated ones is remembered. As in the question of recovery, so here it is evident that a too favourable prognosis should not be given. The only redeeming point as to this high percentage of recurrence lies in the fact that in a large number of cases the hernia could be retained by a truss, when that had been impossible before the operation. In the case of children under ten years of age the statistics are far from encouraging as to either point, in nineteen cases the percentage mortality was $10\frac{5}{6}$ (against $7\frac{1}{2}$ in adults), and of recurrences 21. This number of cases is, however, much too small to allow a definite judgment to be made, and it only remains to reiterate a hope, already expressed in this journal, that in the course of the present year a sufficient number of cases may be published by English surgeons to allow definite opinions to be formed, both as to the indications and as to the all-important point not touched upon, viz., the length of time for which a truss must be worn subsequently.

REVIEWS AND NOTICES OF BOOKS.

THE REGISTRAR-GENERAL'S REPORT FOR 1882.[1]

For any one who has a love of statistics there is no more fascinating or suggestive volume published than that which yearly issues from the General Register Office. The nation's internal history—its marriages and its child-bearings, its illiteracy, its carelessness and folly, its diseases and its accidents, its loss of life and its surrender of life—are all so vividly exposed in this Annual Blue Book, that the man must have the imagination of a broomstick who can see nothing in it but mere figures. The Registrar-General does his best to make it interesting, and in his introductory report points out many of the questions of vital importance suggested by a consideration of the succeeding tables. Few men, however, we fear, even in our own profession, quite realize the amount and value of the work done at Somerset House, and fewer still take an intelligent interest in it. And yet the compulsory collective investigation, which has been carried on at Somerset House for over forty years, is one of the most important works that the State is engaged in; and as the years and decades glide by may be expected to furnish us with ever more and more trustworthy guidance in matters affecting the social welfare. To take only a single instance of the sort of help that may in the future be expected from the General Register Office, in the course of last year the Registrar-General was asked by the Educational Department whether the statistics of his office showed any deterioration of health in the children of school age. He was asked, in fact, whether the belief as to the deleterious effects of educational over-pressure had any more substantial ground than the *ipse dixits* of the doctors, and the reports of scattered cases. And with the assistance of Dr. Ogle, he was able to show that while the general death-rate of children between the ages of 5 and 15 had fallen from 6·3 per 1,000 in the years 1861–70 to 5·1 in the years 1871–80, and the zymotic death-rate had fallen from 2·9 to 2·1, that from nervous diseases had remained stationary at 0·5. There has been a further fall, he also shows, in the two former categories in the years 1881 and 1882, but no fall in the category of nervous diseases. So far then the statistics, which, we may add, have been further elaborated by Dr. Rabagliati in last week's *Spectator*, tend to support the theory that there is a real injury to children from over-schooling; but the Registrar-General is compelled to add the caution that we must be very guarded in drawing conclusions from these figures; for "the causes of death to which children succumb are far from being stated in medical certificates with such care and precision as would justify us in attaching much practical importance to slight fluctuations under one or another heading."

This, indeed, has been the complaint in many succeeding annual reports, and though Sir Brydges Henniker admits a progressive improvement in accurate diagnosis and specification of causes of death, he finds it necessary to again appeal, as he did last year, to medical practitioners to use still greater care and precision in filling up death certificates. Every one will admit that this appeal is justified, and most will deplore that it should be necessary. In the year under consideration, for instance, the cause of death was simply stated as "dropsy" in as many as 1,852 certificates, and it must at once occur to the medical reader that where the diagnosis was of such a very amateur character, the treatment can hardly have been of a much higher order. Much of this inexact certification may, no doubt, have been due to carelessness, or to a deficient recognition of responsibility; but a layman would be warranted in assuming that some at least of these 1,852 cases would not have appeared any the sooner on the death register if they had been altogether deprived of the

[1] Forty-fifth Annual Report of the Registrar-General of Births, Deaths and Marriages in England. (Abstracts of 1882). London, Printed by Eyre and Spottiswoode.

advice of their medical attendants. In other cases the theory of carelessness is less tenable. In 453 cases, for example, the cause of death was certified as pyæmia or septicæmia, without further specification. The Registrar-General took the trouble in all these cases to send out letters of enquiry requesting further detail, and he succeeded in eliciting the information that 123 of these cases were connected with parturition, while 170 were due to diseases and injuries. The same process was gone through in the case of 432 deaths of women of child-bearing age, certified as due to peritonitis, and it was ascertained that in 179 the peritonitis was connected with parturition. The whole result of these letters of enquiry was to add no less than 428 deaths to those assigned to puerperal fever or to other incidents of childbirth, and to obtain a puerperal mortality of 5·09 per 1,000 children born, instead of the lower figure of 4·61, at which the carelessness and reticence of medical practitioners, if uncross-examined, would have left it. In connection with this subject the Registrar-General points out that there has been during the last two years a marked increase in the mortality from puerperal fever, with, at the same time, an increase in the mortality from erysipelas. "This coincidence" he adds "deserves careful consideration on the part of those engaged in midwifery practice." The increase is disappointing. The conscience of the members of the profession as to their share in the production of puerperal septicæmia has been so deeply moved of late years, and the teachings of both the carbolic and the cleanly schools have been so widely impressed, that we should naturally expect to find a diminution rather than an increase in the cases of puerperal infection. Sir Brydges Henniker's figures show either that the utility of antiseptic precautions in midwifery practice is overrated—possibly they make men bold to do things which they would not have done but for the fancied security derived from them—or else that the Listerian doctrine has not yet penetrated very far down in the profession. A well-known London accoucheur once said in our hearing that antisepticism had abolished all anxiety from midwifery practice. We doubt very much whether some at least of the unfortunate practitioners who recorded the 2,564 deaths from puerperal fever in 1882 would speak with so light a heart.

There are other points in which the want of precision in medical certificates of death interferes with the usefulness and trustworthiness of the Somerset House statistics. Some of the vagueness is no doubt due to the fact that science has not yet made up her mind on certain points, and cannot give authoritative teaching upon them. The average medical mind, for instance, is quite a chaos with regard to the proper nomenclature of cases of pellicular sore-throat, and the Registrar-General complains that it is not uncommon to find all the fatal cases of throat disease in some one medical man's practice in a small area returned as cases of diphtheria, while all those in the same area in a second man's practice are returned as ulcerated sore-throat or simply as sore throat. Hence all comparative statistics as to the prevalence and fatality of diphtheria are entirely untrustworthy. In the case of other diseases in which there is now a fair amount of precision in diagnosis, the vagueness of past records prevents us from drawing any reliable comparison. Thus we find in one of the most interesting tables in the present volume (Table 31, p. lx.), that since the years 1858–60, the mean annual mortality from cancer per 1,000,000 persons living has increased from 335·7 to 532, that from diabetes from 25·7 to 47, and that from diseases of the urinary system from 218 to 394. Such a bald statement would be a little startling were it not borne in mind that in the meantime the mortality from ill-defined and not specified cases has fallen from 2,290 per 1,000,000 to 1,154, and that some at least of this decrease must have contributed to swell the increase under the head of diseases so frequently overlooked as those we have mentioned. Another heading under which there has been a marked and progressive increase of mortality during the last quarter of a century, has been that of "premature birth," the statistics of which have risen from 379·0 in 1858–60 to 473·4 in 1876–80, the rate of 1882 being 471. The mortality from congenital malformation has also risen from 57·7 in 1858–60 to 85 in 1882. Now it is pointed out by the Registrar-General that much of this augmented infantile mortality *may be* connected with the marked increase in the employment of women in industrial occupations. That he cannot say *must be* instead of *may be*, is due to the fact that the certification of the causes of death in the case of infants has always been extremely vague, and that the apparently increased mortality from premature birth and congenital malformation may be really due to the transference of deaths from one cause to another. We think we have said enough to show how much the return for the work and money spent on the Registrar-General's Office depends on the careful and conscientious co-operation of the medical practitioner, how greatly it has been injured by careless certification, and how incumbent it is on all of us conscientiously to give what help we can towards making the Somerset House reports as trustworthy as possible. There are many other points suggested by the present volume which are well worthy of mention, had we space enough. But we must refer the reader to the book itself, which, with its predecessors, ought to be carefully studied by every medical reader.

ABSTRACTS AND EXTRACTS.

PHARMACOLOGY AND THERAPEUTICS.

The Excretion of Mercury.—A series of experiments undertaken by Dr. Schuster, of Aix la Chapelle, to determine the exact mode in which the excretion of mercury takes place after its continued medicinal employment, was published by him in 1881. He found that after treatment by inunction, the mercury was slowly but regularly excreted for as long a period as six months, being traceable both in the fæces and in the urine. In the latter, however, he occasionally failed to find any traces of it, although after a short interval it would appear again as freely as before. A fresh series of investigations recently recorded by him in the *Centralblatt für die Medicinischen Wissenschaften* (No. 16, 1884) have proved that this apparent irregularity of excretion was in reality due to the method of investigation, which he subsequently found to be in-

sufficient to detect known quantities of mercury which had been added to healthy urine. An improved chemical process employed by Dr. Schridde, capable of detecting one-tenth of a milligramme in a litre of urine, has proved that the excretion of mercury goes on continuously, with the urine as well as with the fæces, and by its means Dr. Schuster is still in a position to prove that this excretion does not continue for more than six months after the discontinuance of the use of the drug.

The Treatment of Lupus.—Believing that lupus is just as much a manifestation of scrofula as phthisis, or bone or gland disease, Mr. J. W. Taylor (*Birmingham Medical Review*) makes certain suggestions in accordance with that belief for the treatment of this disorder. The residence should be in a warm and dry climate, the house should be well ventilated, but free from draughts, out-door exercise should never be taken when the weather is cold and wet. The food should be good and varied. Cod-liver oil, when it can be taken, is strongly recommended, and Parrish's food has proved very useful. For local treatment Mr. Taylor recommends scraping with the curette in preference to caustics or scarification. It is best to attack a small part at a time, and remove the disease thoroughly; this treatment is best adapted to those cases where the new growth and ulceration proceed equally; when the latter is in excess, the disease generally gets well without any local remedy; when the former is in excess, free removal is the best treatment.

Iodide of Sodium *versus* Iodide of Potassium.—Not long ago we had occasion to advert to the use of the bromide of sodium, in lieu of its potassic congener; and now Dr. Berg, in the *Archives of Medicine*, April, 1884, enters a plea in favour of the iodide of sodium. Both from theoretical considerations and practical experience, he urges its substitution for the potassium salt, making the following claims for it: (1) It can be used therapeutically for almost all, certainly the chief, purposes for which the potassium salt is used, and, he believes, with similar beneficial effects. (2) It is more assimilable by the digestive organs locally and by the general system. (3) Many of the local and general undesirable effects produced by the potassium salt do not follow the use of sodium iodide. Dr. Berg therefore appeals to those having extensive opportunities to give it a fair trial.

Protracted Lethargy after large doses of Bromide of Sodium.—In the *Boston Medical and Surgical Journal*, March 13th, Dr. E. G. Cutler reports the case of a patient who, in trying to carry out an advertised "cure" for the morphia habit, had taken, according to directions, *sixty* grains of sodic bromide three times a day for the first day; three doses of seventy grains each on the second day; three of eighty grains on the third day—and so on, until, when one hundred and twenty grains had been taken thrice a day, the cure was to be complete. This programme was carefully followed out for a whole week, on the last day of which he could scarcely be made to swallow the prescribed doses. In four days later his lethargy was complete: no reflex action of any kind could be excited: nothing could be swallowed: respiration was slow and shallow: temperature slightly sub-normal: urine was secreted (but not voided) at the rate of about one ounce a day. The treatment comprised —enemata of milk, beef tea, with small doses of alcohol, of strychnia, and of nitre, and general faradization. On the fifteenth day the conjunctiva was found to be sensitive to touch: on the seventeenth he could be made to swallow, but only slowly, and after much persuasion: on the twentieth day he began to waken, and urine was, for the first time, voided without the aid of the catheter. The power of movement returned in the legs before the arms, and such complicated actions as feeding himself, buttoning the collar and the like, could not be performed for more than a fortnight after he had become thoroughly awake. No cutaneous eruption was observed. The patient was temporarily broken of his morphia craving, but ultimately resumed the habit. Similar cases, in one of which two and a-half ounces of the bromide were taken, and one which ended fatally, are also referred to.

Nitrate of Silver in Spinal Irritation.—Dr. Betz (*Memorabilien*, January,) strongly recommends this as a means of relieving the attendant pain, whatever may be the primary cause of this. A solution of 1 part of nitrate of silver to 100 of alcohol is thoroughly applied twice a-day not only to the painful parts, but also for some distance beyond these, and, when necessary, along the whole spinal column. The liquid penetrates quickly, and soon dries up, producing an agreeably cool sensation, and very seldom gives rise to any irritation of the skin. This painting the parts will have to be continued for weeks, or even months, especially if there is any disease of the spine itself present.

Surgical Employment of Iodoform.—At a discussion on this subject at the Riga Medical Society, Dr. Miram observed that iodoform did not merit the renown it had obtained as a panacea in all surgical maladies; for while its striking antiseptic qualities and handiness were acknowledged, its employment had its shady side, as when it gave rise to poisoning, to prevention of immediate union, and to the formation of iodoform abscesses. It required adaptation, in fact, to individual cases. In ophthalmology, Dr. Stavenhagen had found it useful in phlyctenæ, conjunctival ulceration, and affection of the lachrymal sac; but had been disappointed with it in pannus and blenorrhagic affections. Several speakers gave but a very qualified approval of its employment.—*St. Petersburger Medicinische Wochenschrift*, May 10.

Sulphate of Iron in Hemorrhoids and Proctocele.—Dr. Wimpelberg recommends an ointment, containing twelve grains of the subsulphate to the ounce, to be applied night and morning. In cases of proctocele, he uses the persalt internally, in doses of two grains, three times a-day, in conjunction with the local use of the ointment.—*New York Medical Journal*, April 12th, 1884.

The Treatment of Whooping-cough.—The *Midland Medical Miscellany*, of April 1st, contains an interesting paper on the treatment of whooping-cough, by Dr. Dolan, whose Fothergillian Essay on Pertussis is probably familiar to our readers. The whole of the remedies in common use, as recently compared in a paper by Professor Heubner, are considered, and tabulated as to results. Belladonna for general results, and salicylic acid, in the form of spray (½ to ½ per cent.), for immediate relief, are credited with the best average of efficacy. Dr. Dolan deduces, with some force, from this conclusion (the salicylic acid having, in his belief, merely a germicidal action) a support to the theory advanced in his previous essay of the fungoid origin of pertussis. The special form of microbe, rejoicing in the name of the bacillus pertussis, and believed to be pathognomonic of the disease, has been described and shown by Professor Berger. Dr. Dolan observes, however, that we must "recognise, as in phthisis, that the finding of the bacillus is only the first link, experiments must determine the connection between the organism and the disease." So obviously and readily contagious is pertussis, that such experiments, when performed, ought soon to furnish a definite conclusion.

Iodoform in Erysipelas.—There would seem to be no limit to the uses to which iodoform may be put in restoring the human form divine to its pristine vigour. In the May number of the *Practitioner*, Mr. Clark Burman commends it for erysipelas. He used a solution of one part of iodoform in ten parts of collodion, and found that after a single application of this the pain and heat were relieved, and that the tendency to spread ceased. This good result could not be attributed to the internal treatment adopted, nor to the collodion, because Sir James Paget expressly states that it does not check the spread of the disease.

REPORTS OF SOCIETIES.

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, JUNE 5TH, 1884.

JONATHAN HUTCHINSON, Esq., F.R.S., President, in the Chair.

The Prevention of Blindness from Ophthalmia Neonatorum.

THE SECRETARY read the following report by the Committee appointed to investigate this subject:—

In answer to a very large number of enquiries from private persons, ophthalmic and lying-in hospitals, and from Institutions for the Blind, we have received 23 statistical replies, all of them from Institutions for the Blind.

Four of these, viz.: those of the Belfast Deaf, Dumb and Blind Institution, the London Society for Teaching the Blind to Read, the Blind School at York, and the Blind Institution at Hull are decidedly superior, being tolerably explicit. Moreover, the answers appear to us from other evidence to be trustworthy. In the first (Belfast), 30 per cent. of the persons concerned owe their blindness to Ophthalmia Neonatorum. In the second (the London Society, &c.), 20 per cent. are certainly blind from this disease, but from the extremely frequent occurrence of "congenital cataract" and "cause unknown" in cases of blindness from birth, we are of opinion that at least another 10 per cent. should be added, thus making again 30 per cent. In the third (the Yorkshire School), 41 per cent. are blind from this cause. And in the fourth, that at Hull, five cases out of fourteen personally examined by Dr. Rockliffe, 35 per cent., are with certainty attributable to the same disease.

The statistics of the other Institutions are so inexplicit as to be of little direct value, but their figures, so far as they go, point to about the same results. It will be observed that these numbers agree substantially with those of foreign investigators, notably those of Reinhard, who, on investigation of 22 German Blind Asylums, found 658 blind from this disease among a total of 2,165, = 30½ per cent.

The Committee also recommend the adoption by the Ophthalmological Society of the following resolutions, which they have slightly modified from those originally suggested by Dr. David McKeown.

(1) That the purulent ophthalmia of newborn infants being the cause of a vast amount of blindness, mainly because of the ignorance of the public regarding its dangerous character and the consequent neglect to apply for timely medical aid, it is desirable to instruct those in charge of newborn children by a card, in substance as follows:—

Instructions Regarding Newborn Infants.

If the child's eyelids become red and swollen, or begin to run with matter, within a few days after birth, it is to be taken without a day's delay to a doctor. The disease is very dangerous, and, if not at once treated, may destroy the sight of both eyes.

This to be distributed through the medium of the Poor-law and Birth Registration organisations of the United Kingdom. In England the Relieving Officer, and in Scotland the Inspector of the Poor should, in every case of labour under the Poor-law system, read to and leave with the person obtaining the order for medical aid, or the persons in charge of the patient, a copy of the card. In Ireland the card should be attached to the order for medical aid in such cases, and the person who gives the order and card should, before doing so, read the card to the applicant. The Registrar of births should read and hand to each person registering a birth a copy of the card.

(2) That the advocacy and aid of the medical press be solicited in drawing general attention, and especially that of the authors of text books on midwifery, of the lecturers on the same subject for students and midwives, and of the various institutions which train, and charitable institutions which employ midwives, to this important subject.

(3) That a copy of the first resolution be forwarded to the respective Presidents of the Local Government Boards of England and Ireland, and of the Board of Supervision in Scotland, and such other persons, if any, as may be necessary, and that a deputation be appointed to wait upon the said Presidents and other persons, if necessary, and urge upon them the official adoption of the views therein expressed, and to take such other steps as they consider necessary.

Signed, FREDK. MASON,
Chairman of the Committee.

This report having been adopted, the following members of the Society were appointed to take charge of the report, in accordance with Resolution 3, viz., Sir William Bowman, Bart., F.R.S.; Mr. Jonathan Hutchinson, F.R.S.; Mr. Brudenell Carter, Mr. Tweedy, Dr. David McKeown and the Secretaries.

On the motion of the President, a vote of thanks was accorded by acclamation to the Committee who had drawn up this report, and to the representatives of the Obstetrical Society who had given valuable aid to that Committee.

Exhibition of Cases, Specimens, &c.

Dr. P. H. MULES exhibited a coloured drawing of a typical example of miliary tubercle of the choroid, as seen with the ophthalmoscope, as well as microscopical sections of the tubercles. The patient was a girl, aged 10, who died of acute miliary tuberculosis fourteen days after the apparent commencement of her illness. After death, miliary tubercles were found in the lungs, kidneys, liver, spleen, and cerebral meninges, as well as in the choroid. The drawing shown was made two days before death; there was double optic neuritis, and surrounding the disc in each eye were eight or ten circular nodules, yellowish white at the centre, and passing gradually at the periphery into the colour of the natural choroid. The surface of several of the choroidal tubercles was traversed by a retinal vessel. The tubercles had been examined for bacilli, but none were found. Dr. Mules thought that the ophthalmoscopic appearances, taken alone, were hardly sufficiently diagnostic of tubercle to separate it from other choroidal affections, notably the very early stage of choroiditis disseminata, but, taken in connection with other symptoms, they afforded valuable confirmatory evidence.

Mr. TARGETT showed, for Dr. Brailey, a man, aged 56, who exhibited in a remarkable manner the phenomena of the case described by Messrs. Gunn and Anderson at the last meeting of the Society. He had on the right side paralysis of the external rectus, with dilatation and immobility of the pupil. He gave a clear history of uniocular diplopia on this side, but only in the outer half of the field of vision. Now that the optic discs had become atrophic, this symptom was no longer noticeable. Perception of red and green was wanting. The right knee-reflex was much weaker than the left. Without any local cause he had nocturnal incontinence of urine. He had none of the usual symptoms of locomotor ataxy. He was probably suffering from constitutional syphilis.

Mr. ADAMS FROST exhibited, for Mr. Waren Tay, a case of serous cyst of the iris, in a man, aged 28. Twenty-four years ago the eye had been injured by a fork, and the development of the cyst dated from that time. Ten years ago an iridectomy was performed. The cyst occupied the upper and inner quadrant of the anterior chamber, extending quite up to its periphery, and reaching about halfway across the pupil. The lower part of its posterior surface was lined by a layer of uveal pigment. The cyst itself was sufficiently transparent for a fundus-reflex to be obtained through it in several places. The pathology of the affection was discussed, and the papers by Mr. Hulke (*Ophthalmic Hospital Reports*, vol. vi.), and M. Wecker (*Gräfe-Saemisch Handbuch*, vol. iv., p. 540) referred to. As bearing on the question of treatment, it was mentioned that, in one of Mr. Hulke's cases, the increased size of the cyst gave rise to sympathetic irritation in the other eye, which subsided on excision of the cyst. In other cases, on the other hand, its excision had been followed by loss of the eye from suppuration. As the cyst in this case was in contact with the cornea and lens, and extended quite up to the periphery

of the anterior chamber, its removal would probably be a matter of difficulty and danger.

Messrs. CRITCHETT and JULER exhibited a living case of disseminated choroiditis occurring in a woman, aged 46. There was a distinct history of syphilis, acquired five years ago. The case was chiefly interesting on account of the great number of large and small yellowish-white patches distributed over the fundus, including the yellow-spot region of the right eye. The left eye had become totally blind three years ago, presumably from the same cause. Very little pigment was to be seen, and the visual acuteness and visual field of the right eye were normal.

The PRESIDENT observed that the form of choroiditis was very unusual, owing to the small size and large number of the white patches. He recalled one case which he had seen, where the patches were similar but not quite so numerous. It occurred in a young lady, aged 15, whose father had suffered from syphilis. There was no other trace of hereditary taint, but the patient recovered rapidly under anti-syphilitic treatment.

Messrs. CRITCHETT and JULER also showed a boy, aged 14, who had sustained a severe wound of the scalp on February 7th. Four days after this accident the eyes became convergent, and he suffered from double vision. There was no loss of consciousness at any time. He made an excellent recovery from the scalp injury, but the squint remained. The convergence was at first attributed to paralysis, but on examination the patient was found to be hypermetropic (5 D). Both the primary and the secondary deviations were equal. The left field of fixation was normal, and the right only indicated a deficiency in the power of the external rectus. The squint was therefore considered to be chiefly concomitant.

In reply to Mr. NETTLESHIP, Mr. JULER said that there had been diplopia, showing that the squint was recent.

The same gentlemen also showed a boy suffering from lamellar cataract, on whom iridectomy had been performed in one eye, and iridodesis in the other.

Messrs. COWELL and JULER exhibited a glycerine jelly preparation and microscopic sections of a case of sarcoma of the choroid occurring in a woman, aged 37. The case was shown at the meeting of the Society in March last, when the tumour could be seen with the ophthalmoscope in the upper and outer quadrant of the fundus. After the March meeting, the whole of the retina became detached, and the eye was excised. Up to the present time there had been no recurrence of the disease.

Acute Optic Neuritis associated with Acute Myelitis.

Dr. SHAKESBY read a paper, prepared jointly by himself and Dr. J. B. Lawford, on this subject. The patient, a girl, aged 17, was admitted into the Royal London Ophthalmic Hospital, under the care of Mr. Streatfeild, on November 26rd, 1883. There was nothing noteworthy in the patient's previous history, and there were no grounds for suspecting syphilis. Her vision began to fail without evident cause on November 9th, and by November 13th she was quite blind. She had neither headache, sickness, paralysis, nor fits, but simply loss of sight. She was a fairly healthy-looking girl, but on examination severe double optic neuritis was found, and she had no perception of light. Thirty-three days after her vision failed she began to complain of paralysis, with loss of sensation, first in the left leg, then in the right. Anæsthesia gradually spread up the trunk and involved the arms, and she had incontinence of the evacuations. During the latter part of her illness she was under Dr. Bristowe's care, in St. Thomas's Hospital. Cystitis came on, she passed offensive purulent urine, and the temperature reached 105° Fahr. Finally she died of peritonitis 62 days from the time when her vision first failed and 29 days after the first appearance of paralysis. At the necropsy, peritonitis, cystitis, and suppurative nephritis were found. To the naked eye, the brain and its membranes and the cerebral sinuses appeared healthy, but there was softening and great congestion of the cervical region of the spinal cord over a space two or three inches in length. The rest of the spinal cord and its membranes seemed healthy. Microscopic examination revealed the presence of acute inflammation in the softened cervical region, in the columns of Goll above it, and in the lumbar enlargement, as well as in the optic nerves, discs, chiasma, and tracts. There was slight inflammation of the meninges about the chiasma, and on the under surface of the frontal lobes. The interest of the case, in the opinion of the authors, lay in the association of acute optic neuritis with acute inflammation of the spinal cord. It had long been known that slight changes occasionally occurred in the fundus of the eye in cases of injury to the spinal column and cord. But it was only comparatively recently that attention had been called to the association of acute optic neuritis with myelitis, independently of injury. Clifford Allbutt, Sequin, Noyes, Steffen, and Erb had noticed its occurrence, and more recently Dreschfeld and Chisholm. The conclusion which Dr. Gowers and Dr. Dreschfeld drew with regard to these cases was, that the optic neuritis and the myelitis were associated phenomena due to a common cause, but that neither depended directly on the other. The case detailed supported this view, for the optic neuritis preceded the myelitis by a month, and there was no evidence at the *post-mortem* examination of any anatomical connection between them. Clinically, such cases were of great importance, as they simulated disease of brain; and their occurrence, however rare, detracted somewhat from the significance of acute optic neuritis as a sign of intracranial disease.

Mr. MULES was able to recall one of the cases referred to, as it had been under his own care at one time. The patient had been taken into the hospital under the impression that it was an example of neuritis due to intracranial disease; subsequently, when incontinence of urine and evacuations began to be troublesome, the patient was transferred to the care of Dr. Dreschfeld.

Recovery from Amaurosis in Infants.

Mr. NETTLESHIP read a paper founded on a number of cases of temporary blindness, or partial amaurosis, observed in infants. He dwelt especially on the question of prognosis, and pointed out that there was a fairly well defined group of cases where the amaurosis was not recovered from; sight was absent or defective from birth, several children of the same parents were often affected, and the parents were often akin. Some of the patients were idiotic, others stupid or weak, others quite intelligent; the optic discs were either healthy or atrophied; in the milder cases, where sight was partly retained, there was often total colour-blindness; in cases of absolute blindness, the pupils still re-acted to light, which appeared to show that the centre of pupillary action in or near the corpora quadrigemina remained intact, although higher centres were absent or atrophic. In cases of amaurosis, in which recovery was probable, the history was of great assistance: it was generally stated that the child could see well for some months, or even years after birth, and then it lost its sight during an illness with cerebral symptoms, often diagnosed as meningitis; the optic discs, in the great majority of cases, were either healthy, or showed merely some slight doubtful pallor; frequently the power of walking, standing, or even sitting, was lost during the same illness. The blindness appeared to last from one to six months, and recovery took place slowly. He thought that in all these cases intracranial inflammation certainly took place, and perhaps spinal mischief as well. The mode by which blindness was produced must remain in doubt until ophthalmoscopic exa-

INTERNATIONAL HEALTH EXHIBITION.

CONFERENCE ON PUBLIC HEALTH.

Monday, June 6th.

Dr. T. J. Dimmock in the Chair.

Dr. Dixon read a paper on "The Compulsory Notification of the Movements of Persons Suffering from Infectious Disease."

Dr. Dixon said that the object of the paper was to show that the present system of compulsory notification of infectious disease was inadequate, and to suggest a remedy. The present system was defective in that it did not provide for the notification of cases of infectious disease occurring in persons who were not permanently resident in the district in which they were living at the time they were taken ill. Persons who were visiting or staying in a district, or who were passing through it, were frequently taken ill with infectious disease, and the fact was not known to the local authority. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey. Cases of infectious disease occurring in persons who were not permanently resident in the district in which they were living at the time they were taken ill were frequently not notified to the local authority, and the fact was not known to the local authority. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey. Cases of infectious disease occurring in persons who were not permanently resident in the district in which they were living at the time they were taken ill were frequently not notified to the local authority, and the fact was not known to the local authority. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey.

Dr. Dixon read a paper on "The Compulsory Notification of the Movements of Persons Suffering from Infectious Disease."

Dr. Dixon said that the object of the paper was to show that the present system of compulsory notification of infectious disease was inadequate, and to suggest a remedy. The present system was defective in that it did not provide for the notification of cases of infectious disease occurring in persons who were not permanently resident in the district in which they were living at the time they were taken ill. Persons who were visiting or staying in a district, or who were passing through it, were frequently taken ill with infectious disease, and the fact was not known to the local authority. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey. Cases of infectious disease occurring in persons who were not permanently resident in the district in which they were living at the time they were taken ill were frequently not notified to the local authority, and the fact was not known to the local authority. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey. Cases of infectious disease occurring in persons who were not permanently resident in the district in which they were living at the time they were taken ill were frequently not notified to the local authority, and the fact was not known to the local authority. Such persons were a source of danger to the inhabitants of the district in which they were living at the time they were taken ill, and also to the inhabitants of the districts through which they passed on their journey.

which was in most places carried out on the same plan as when dust was a marketable commodity. Circumstances had entirely changed, and the Sanitary Authorities should everywhere be their own scavengers, and not trust to the contractors. The neglect by the dust-men of those streets where the people were too poor to fee them for removing it, was a great hardship. Combined drainage of several houses was a source of great inconvenience and danger, since the stoppage of the drain in one house affected others at the same time.

Dr. ALFRED CARPENTER urged the inspection of sanitary arrangements not only at the time of building, but periodically afterwards, and also the employment of all means, especially of gas for cooking, by which the accumulation of dust and consequently the cost of its removal might be diminished.

Capt. GALTON considered that in all new streets a passage giving access to the rear of the dwellings would greatly facilitate the removal of dust, besides giving greater opportunity for the circulation of air, and he regretted that this had been ignored in re-building over old properties. To this defective circulation of the air, he attributed the well known higher death-rate observed in densely peopled localities. And yet, in a block being erected by the Metropolitan Railway Company in the Minories, a closed central court was to be divided by a cross block into two wells of sunless stagnant air!

Dr. Bartlett, Dr. Bernays, Dr. Slater, Mr. Robbins, and other gentlemen also took part in the debate, Dr. BERNAYS insisting that water for drinking should always be drawn from the main. The water supplied by the companies was really as good as could be reasonably demanded, by far the greatest amount of pollution occurring in the storage.

OBITUARY.

PROFESSOR SAMUEL D. GROSS.

To the notice of the death of this celebrated surgeon which we have already given, we may add a few particulars of a career which has been so active and so influential in the United States. It is true that his works have never attained in this country the authoritative position which they hold in the United States, but all must admire his fertile industry, and the admirable use which he made of the opportunities of a long and active life. Quite independently of his reputation as a skilful surgeon, his high principles and ready eloquence raised him to the position of the representative of American Medicine, and in that position he was received and honoured whenever he visited Europe.

Born at Easton, Pennsylvania, in 1805, Samuel D. Gross had the good fortune to become one of the pupils of Prof. McClellan, of Philadelphia, who was greatly interested in the foundation of Jefferson Medical College, at which Gross graduated, and in which he was hereafter to become celebrated as a teacher for twenty-six years. Before this came to pass, however, he filled posts of importance at Ohio, Louisville, Cincinnati, and New York, always pushing, wherever the centre of professional activity, either by publishing his own works or the translations of others, and by the encouragement or foundation of various medical institutions. At Cincinnati he delivered the first course of lectures on pathological anatomy ever heard in America, and his "Elements of Pathological Anatomy" was the first systematic work on the subject that appeared there. Soon after returning to Philadelphia, the first edition of his "System of Surgery" appeared; this has since gone through five other editions, and will be the work through which his name will remain one of authority. He produced various other works of less importance, as his treatises on "Diseases of the Urinary Organs," "Wounds of the Intestines," "Foreign Bodies in the Air Passages," &c., and his contributions to the medical periodical press have been very numerous. His eminence as a surgeon and as a representative man was freely acknowledged in this country, wherein he has received honours from both our universities, and just before his death from that of Edinburgh, and the principal medical societies. After a laborious career as teacher of surgery, extending over forty-two years, he resigned his chair at Jefferson College in 1882. "As a teacher, a lecturer, and an operator," the *Philadelphia Medical News* observes, "Dr. Gross was greatly admired. He was an untiring student, systematic and economical of his time, and while punctually fulfilling his engagements as professor and practitioner, he was enabled to keep himself thoroughly informed in medical and general literature. His extensive knowledge of disease, added to a great faculty in diagnosis, enabled him to grasp at a glance the salient features of a case. He was never satisfied unless his work was thoroughly done, and felt that in every case he had a triple duty to perform—first, and above all, to his patient, secondly to his pupils, and lastly to himself. He was always a warm advocate of a higher grade of education, and a more thorough course of instruction for the students. Whether as surgeon, author, or lecturer, the stamp of his individuality has been indelibly impressed upon the history of science in America. He was never content simply to keep pace with the stride of scientific research, but has often been the pioneer to open up unexplored regions. With him science and humanity have gone hand-in-hand, and, as a result, the technical and general literature of the country has been enriched by his works, and humanity made happier by the greatness of his heart."

Dr. Gross died on May 6th, in the 78th year of his age having during the preceding three months exhibited failing strength, which was attended with derangement of his digestive power, and consequent death from exhaustion. At the autopsy there was found marked gastric catarrh, with irregular thickening of the mucous membrane, fatty heart, and a large cyst of the kidney. The brain weighed 48 ozs.; its convolutions were numerous, and its sulci deep. His remains were cremated at Washington, Pennsylvania, and then brought back to Philadelphia, under the escort of the family and friends of the deceased. The ashes, weighing about 7 lbs., were hermetically sealed in a tin box and placed in the coffin in which the body had been carried. On reaching Philadelphia, they were enclosed in a marble urn, unornamented and without any inscription, and placed in the Woodland Cemetery. The Jefferson Medical College intends establishing a Gross Professorship of Pathological Anatomy, and the American Medical Association will erect a statue to his memory.

GENERAL CORRESPONDENCE.

THE SANITARY CONDITION OF NICE.

[To the Editor of the Medical Times.]

SIR,—It may, I think, be of interest to your readers and to all those who are in any way concerned for the prosperity of the health stations on the Riviera, to be furnished with an accurate account of the epidemic of typhoid fever at Nice, in the autumn of last year. To the exaggerated reports which appeared in many newspapers, both in England and the Continent, it was in great measure due that the visitors to Nice and along the whole of the Riviera last season were far fewer than usual.

It is to be regretted that the Medical Society of Nice did not at once make known the results of the enquiry they instituted, since that would, I think, have done much to quiet the general anxiety on the subject. They have now, however, published them in their organ, the *Nice Médical*, and I ask for space to print the report in a condensed form, at the same time that I forward to you a copy of the original. On November 23rd, 1883, a sub-committee was nominated to draw up a set of questions, which were sent to all the medical men practising in the city, to which 63 returned replies. Eight stated that they had observed a greater number of cases of typhoid fever than usual in the previous autumn, and 16 others added that they had, during the same time, seen several instances of fever of a remittent type, similar to, though not identical with, typhoid.

In the town itself 156 cases of true typhoid had been noted in private practice, 73 in the Civil Hospital, and 38 in the Military Hospital; or altogether 265. In addition to these, 43 cases of remittent fever had been observed in general practice in the town. A few only of these cases had occurred in June, July and August, but the greater number in September and October. The disease reached its maximum of prevalence in October; it still continued, though with lessened frequency in the first half of November, but diminished with great rapidity in the second half of that month. Out of the 156 cases, 84 occurred in persons in comfortable circumstances, 20 among the working-classes, hospital cases, of course, excluded. Of the 156, 116 took place among the resident population, or among strangers resident in Nice for more than six months, and 12 among persons who had dwelt there for a shorter time. The cases were pretty equally distributed throughout the whole city; the barracks, on the Place St. Dominique, being the only spot that could be regarded as a focus of the disease.

The general sanitary condition of the dwellings in which fever cases occurred, is stated in 132 out of the 156 cases, and is said to have been good in 65 instances, apparently good in 6, tolerable in 38, and positively bad in 23. In 18 of these last cases, the bad condition of the privies, or water-closets, is especially noticed. The majority of cases were isolated; but once 3 cases occurred in the same family, 2 in five, and 2 four times in the same house, though not in the same family. With reference to the general character of the fever among the cases occurring in the town, it was benign in 53, moderate in 9, severe in 24, and dangerous in 31 out of 120 in which this point is referred to. The mortality in the town was about 16 out of 156, or 10 per cent.; 10 in 73 in the Civil Hospital, or 13 per cent.; and 3 in 38 in the Military Hospital, or 8 per cent.; or in other words, the total mortality was 29 in 265, or 11 per cent. If one assumes the number of cases not reported by the few medical men who made no report to have been 35, we arrive at a total of 300 cases, and a mortality of about 33; neither a large number nor a high mortality for a city whose population, exclusive of visitors, is between 70 and 75,000. It will, moreover, be observed that the epidemic began at a time when those who resort to Nice in quest either of health or of amusement, had already quitted it, and that it had almost ceased before the return of the greater number; for at the time of the publication of the report on December 7th, only 6 cases had occurred in the town since the 14th of November, and none at all in the Military Hospital.

At Nice, as often happens elsewhere, good has come out of evil. The conviction has forced itself on almost all, that perfect frankness is invariably the best policy, and that the endeavour to conceal a known evil issues only in gross exaggeration of its extent.

It has further awakened the authorities of the city to a perception of the need for immediate action, in order to improve in all respects the sanitary condition of the town. The eminent engineer M. Durand-Claye has been called in to advise as to the thorough drainage of the town, an enterprise the difficulty of which will be at once appreciated by all who bear in mind that the Mediterranean is a tideless sea.

A special sub-commission of the municipality has been formed, under the name of "*Commission d'Hygiène et de Publicite*," to study all questions connected with the sanitary state of Nice, and the publication of its vital statistics. The creation of a *Bureau d'Hygiène* has been resolved on, such as exists at Havre, Rheims, Nancy, and other towns in France, and which answers to the Sanitary Authority in England, and controls the work done here by the Medical Officer of Health and his subordinates.

It must not be forgotten that sanitary science, and boards and officers of health were unknown in this country fifty years ago. We must not then criticise too severely the imperfect projects of our neighbours, nor wonder that the steps of those to whom a road is altogether new should sometimes falter. But more than this, we are bound, at least to my thinking, to do our best to help every effort, and not, when in quest of health or of pleasure we go to regions where both are proffered with a lavish hand, act as though we owed nothing in return, and murmuring at ignorance we do nothing to enlighten, and complaining of defects we do not seek to remedy, waste in idle dissipation or ignoble sloth the wealth and time and talents lent to us for others as well as for ourselves.

I am, Sir, yours, &c.

C. WEST.

Bolton Row, W., June 6th, 1884.

HYDRO- AND PYO-SALPINX.

[To the Editor of the Medical Times.]

SIR,—In reply to Dr. Horrocks, permit me to say that two classes of cases are evidently mixed up in his mind, those in which rupture takes place and proves fatal by general peritonitis (and this I fancy must be confined to pyo-salpinx), and those cases in which rupture does not occur, but where the sufferers go on year after year unrelieved, wandering about from hospital to hospital. I gave him a case of that sort, and gave him names of men who had had the patient under care, and if he has not been able to identify her it is no fault of mine.

I said at the Obstetrical Society, and I say again, that it is extremely probable that few of the cases of rupture followed by acute peritonitis are got into hospital. I had no idea that the disease was so prevalent or so fatal that in one hospital, the Middlesex, fifteen such cases could be found, with one-half of them fatal, in three years. Therefore, I said in my letter that I had clearly under-estimated the fatality of the disease. We can form no idea yet, perhaps we never shall, as to the proportion between the total number of cases of the disease and those in which fatal rupture occurs, but it is perfectly certain that the total number of cases wandering about the world is very large. At the discussion on the subject at the London International Medical Congress, Sir Spencer Wells expressed the opinion that they must all go to Birmingham. Though there is more truth in this than he intended, it is perfectly clear that they exist abundantly in New York, Liverpool, and elsewhere, when they are properly looked for, and they cannot be rare at Guy's Hospital. I believe they constitute about two per cent. of the total number of out-patients at a special hospital, and I have not the slightest doubt but that there are fifteen or twenty such cases attending the out-patient department of Guy's Hospital under Dr. Horrocks' care at the present time. Dr. Horrocks claims to have found one at last and to have cured it without the knife. He may be perfectly correct, but he must forgive me if I doubt him. When he has had more experience in these matters, he will be less certain of his diagnostic powers. For my own part, I am never sure of my diagnosis until I have the diseased appendages outside. I have now had a very large experience of cases that have not got well without operation, but I have not had a shadow of reason to believe that I have ever seen a case get well in any other way. I do not deny that they may, they possibly do in large numbers, but I have seen none, and the physical conditions of the disease certainly make such a result look very improbable. At any rate, when a woman has, in her opinion, and the opinion of her medical advisers, suffered sufficiently from what Dr. Horrocks calls "local applications and internal remedies" at the unavailing hands of the physicians, she had better be turned over to the surgeon for the removal of her diseased appendages, and if she has the history and record of symptoms which I have over and over again indicated, the chances are four out of five that she has occluded and distended tubes, curable by nothing short of surgical interference. Dr. Horrocks clearly has either forgotten or has never read the statement I have often made, that all these cases, without exception, have been long under either my own care or the care of others, and that the "local applications and internal remedies" have proved useless—often they have proved disastrous.

I am, Sir, &c.,

LAWSON TAIT.

Birmingham, June 9th, 1884.

THE ETHICAL COMMITTEE OF THE METROPOLITAN COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

[To the Editor of the Medical Times.]

SIR,—Towards the end of last year a complaint was made by a medical officer of one of the smaller hospitals of London as regards the conduct towards him of two of his colleagues. The matter was referred to the Arbitration of the Ethical Committee of our branch, and after bestowing on it much time and care, an award was arrived at which was subsequently considered and confirmed by the Council of our branch, and signed by me as Chairman of the Committee and as President of the branch.

This award was communicated to the three parties specially interested, and it was hoped that the result would be that all past differences would be forgotten, and that for the future complete forbearance would be shown by the several parties concerned towards each other.

I extremely regret to find that this award has been recently—after a lapse of five months from the time it was made—reprinted and extensively circulated, not only in England but in Scotland, without any word of explanation as to who issued it; and my name being attached to it, the circular has the appearance of being forwarded by myself, and with the sanction of the Council.

I am in consequence obliged to state that the reprinting of the award has been done, and the circulation of it has been made, entirely without my sanction or knowledge, and without the sanction or knowledge of the Council; and at the meeting of the latter yesterday, I was unanimously requested to state that it was never intended that the award should be used in such a manner as it has been, and that the reprinting and circulation of it have the complete disapprobation of the Council.

I am, Sir, faithfully yours,
CHARLES J. HARE, M.D.,
President of the Metropolitan Counties Branch of the British Medical Association, and Chairman of the Ethical Committee of the Branch.

Berkeley House, Manchester Square, W.,
June 7th, 1884.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE ordinary meeting of the Council was held on Thursday last. The election of Conservator of the Hunterian Museum (in succession to Professor Flower) was postponed until Thursday next. The Examiners in Medicine and Midwifery were re-elected. A vote of thanks to the President for representing the College at the Tercentenary Festival of the Edinburgh University was passed. The nomination of candidates to the various professorships was next proceeded with: Mr. Wood and Mr. Lund in Surgery; Professor Schäfer as Arris and Gale Lecturer on Physiology: Messrs. W. K. Parker, Brailey, Hill, and Treves to the various lectureships in connection with the Museum. The proposal for scheduling the physiological subjects for examination was referred to the Nomination Committee to report upon.

Mr. Heath gave notice of motion "That an extraordinary meeting of Council be held to consider the mode of electing the President, and the alterations to be made in the method of proceeding in that election."

A letter was read from Dr. Edwin Morris, suggesting, among other things, that alterations in the charters which do not give equal electoral rights to Fellows and Members would not be generally acceptable; that the President be elected from among the general body of Fellows and Members by the Council. It was decided that the letter be acknowledged, and that the writer be thanked.

The Council then adjourned.

ASSOCIATION OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

AN influential meeting of Fellows of the Royal College of Surgeons was held on Thursday afternoon, at the Rooms of the Medical Society. Mr. Paul Swain (Plymouth) was voted into the chair. He remarked that the immediate cause of the formation of the Association was the rejection by the Council of the College of Surgeons of the resolutions which were passed on March[29th last. He felt that the old Association, after the statement made by Mr. Wheelhouse at the College on that occasion, had practically ceased to exist. It appeared to him, therefore, needful to start a new Association, and up to the present time, no less than 200 Fellows had joined. The reasons why such an Association should be formed were twofold. First, to extend and maintain the rights of the Fellows; secondly to promote necessary reforms. With regard to the first, he considered it advisable that they should have the right to discuss the annual report, if not to elect the President. At any rate, the President should no longer be elected by rotation. There were many matters requiring reform, *e.g.*, at the present moment all the Members of the Court of Examiners were on the Council. This was an unfair preponderance, and five should be elected from outside that body. They should not be eligible for re-election at the end of five years. With regard to the members, he thought they had certain corporate rights which should be recognised, and he advocated their admission to meetings, with the right of speaking at them.

Mr. Tweedy moved, and Mr. Allingham seconded, "That a Society be formed to promote the general interests of the Fellows, and to consider all matters relating to the constitution, government, and administration of the College, whether in its corporate, examining, academical, or political capacity, and that this Society be called 'The Association of the Fellows of the Royal College of Surgeons of England.'"

This resolution was passed unanimously. Office bearers were then appointed—President, Mr. G. D. Pollock; Treasurer, Mr. Willett; Hon. Secretaries, Mr. Morgan and Mr. Bruce-Clarke, and a large committee was elected.

Mr. Pollock now took the chair, and the formal business of the meeting was entered upon.

It consisted chiefly in considering and re-affirming the following resolutions, which were passed at the meeting of Fellows and Members at the College of Surgeons in March last:—

(1) "That in the opinion of this Association it will materially conduce to the welfare of the College that the Fellows and Members should be invested with a larger share of its management."

(2) "That it is desirable that no alteration in the constitution or relations of the College shall be effected without the consent of the Fellows and Members convened to discuss such alteration."

(3) "That there shall be an annual meeting of the Fellows and Members, at which the annual report of the Council shall be presented, discussed, and if approved, adopted."

It was then moved by Mr. John Morgan, and seconded by Mr. Swain, "That a request be forwarded to the Council of the Royal College of Surgeons of England to receive a deputation from this Association, and that a Sub-Committee be formed to represent the opinions of this Association to the Council of the College, and to take such steps as may seem desirable to further the objects of this Association."

It was unanimously decided that each associate should contribute five shillings towards the expenses of organization.

UNIVERSITY OF CAMBRIDGE.—First examination for M.B. Degree. The following have been examined and approved:—

Arkwright, Trinity; Armitage, Trinity; Barker, Catharine's; Barnard, King's; Barton, Caius; W. H. Beaumont, Down; Bickersteth, Trinity; Blaikie, Caius; Blaker, Cavendish; Bond, John's; Bowen, King's; Bradley, Caius; Brooke, Pembroke; E. Browning, Clare; Bulstrode, Emmanuel; Burd,

Caius; Carey, Emmanuel; Carter, Pembroke; Cautley, King's; Cocksedge, Caius; Colclough, Caius; E. Hunt Cook, John's; Cooper, Caius; Copeland, King's; Fox, Trinity; Cresswell, Cavendish; Crisp, Caius; G. H. S. Daniell, Caius; Danials, Trinity; De Jersey, Pembroke; Dickenson, Caius; Dickenson, Down; Dickson, Jesus; Douty, King's; W. H. Dumergue, Corpus; Duncan, Caius; A. C. Dupp, Corpus; England, Caius; Evelyn, Caius; Ferguson, Caius; Fitzgerald, Caius; M. G. Foster, Trinity; H. A. Francis, John's; Gervis, Trinity; Goodman, John's; Hamer, Christ's; Hardwicke, non-coll; Harrison, John's; Heberden, Jesus; Hewer, non-coll.; Heley, Pembroke; Holden, Caius; Hopkinson, Emmanuel; Hounsell, Caius; Howard, Trinity; E. L. Jones, non-coll.; H. R. Jones, John's; W. Kayess, Caius; Kent, Caius; Kidd, Trinity; King, Cavendish; Lambert, Pembroke; C. W. Leaf, Trinity; Ledlie, Christ's; Light, Clare; Lipscombe, Caius; G. T. Lloyd, John's; Luard, Catherine; H. H. Maclure, Pembroke; M'Conkey, Caius; Macdonald, Jesus; Macpherson, Trinity; Major-Brown, Downham; W. Malden, Trinity; Manby, Catherine; Manners, Pembroke; A. L. Marshall, Clare; May, Trinity; Michell, Caius; Miley, Trinity; Morrice, Trinity; Newton, Pembroke; Neilsen, Caius; Ogilvie, King's; Olive, John's; Panting, King's; Parker, Catharine's; G. H. Pearce, Cavendish; Penny, Queens'; Pearson, Trinity; C. S. Pollock, Trinity; Prowse, non-coll.; Punch, John's; Redmayne, Trinity; Renfry, Christ's; R. J. Roberts, non-coll; Rowe, Pembroke; Rutherford, Trinity; G. R. Sauaders, Caius; F. W. Saunders, Trinity; Savory, Cavendish; Scott, Caius; Servaes, King's; Shore, John's; Sibley, Pembroke; Skelding, Caius; Smyth, King's; Sprigge, Caius; M. H. Spencer, Trinity; D. P. S. Stephens, Selwyn; Tatham, Clare; E. Taylor, Pembroke; Van, Caius; Weber, Trinity; Webster, Caius; F. Westcott, Peterhouse; Whitby, Emmanuel; Wilde, Clare; Williams, A. H. John's; Roll Wingfield, Christ's; Wynne, Catharine's; Yeoman, Pembroke.

ROYAL COLLEGE OF SURGEONS.—The following members of the College having undergone the necessary examinations for the Fellowship, at meetings of the Court of Examiners, on the 29th, 30th, and 31st ultimo, were reported to have acquitted themselves to the satisfaction of the Court, and at a meeting of the Council yesterday, the 12th instant, were admitted Fellows of the College, viz.:—

Messrs. George Pearce, M.D., St. Andrews, Leicester, diploma of membership dated April 25th, 1862, and J. S. Kaeser, M.D. Bâle, Queen Anne Street, W., April 14th, 1882, students of St. Thomas' Hospital; Thomas Thyne, M.D. Edinb., Twickenham, July 28th, 1863, of the Edinburgh School; Henry Briggs, M.B. Edinb., Liverpool, July 24th, 1877, of the Liverpool School of Medicine; J. W. Sanders, L.R.C.S. Lond., Bethnal Green, November 17th, 1878; R. Howell Perks, L.R.C.S. Lond., Hampstead, July 24th, 1881, and L. Albert Dunn, M.B. Lond., Brighton, April 20th, 1882, of Guy's Hospital; W. George Evans, L.R.C.S. Lond., Colchester Street, S.W., May 20th, 1880, and E. Hermus Holthouse, M.B. Cantab., Helidon, Northampton, January 21st, 1881, of King's College Hospital; G. C. Robins Bull, L.R.C.P. Lond., Dover, July 21st, 1880, of St. Mary's Hospital; C. Egerton Jennings, L.R.C.P. Lond., Malmesbury, April 19th, 1881, of the London Hospital; Charles Stonham, Gower Street, W.C., November 17th, 1881, of University College Hospital; J. Macdonald Rogers, L.S.A. Berners Street, W., January 26th, 1883, and J. Bland Sutton, L.R.C.P. Lond., Gower Street, W.C., April 4th, 1882, of the Middlesex Hospital; R. L. Knaggs, B. A. Cantab., and L.R.C.P. Lond., Putney, November 14th, 1883, and Walter Fowler, M.A. Cantab., Old Burlington Street, November 15th, 1883, of the Cambridge School; Sinclair White, M.D. Dub., Sheffield, of the Galway School of Medicine, and J. Follett Bullar, M.B. Cantab., Southampton, July 30th, 1880, of St. Bartholomew's Hospital.

Three other candidates were reported to have passed their examinations to the satisfaction of the Court, and on their attaining the legal age of 25, will receive their diploma. Seven candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for twelve months. Twenty-eight were examined as compared with eighteen at the corresponding period of last year. At the same meeting:—

Mr. W. J. Collins, M.D. Lond., Albert Terrace, N.W., July 28th, 1880, of St. Bartholomew's Hospital;

who passed in November last, having since attained the legal age of 25, was also admitted a Fellow of the College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 5th, 1884:—

Lewis Brown, 28, Chorley Old Road, Bolton, Lancashire; James Russell Watson, 31, Moore Street, Chelsea.

The following gentlemen also on the same day passed their primary professional examination:—

Philip Henry Hensley, King's College; Frederick William Berry South, Guy's Hospital.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The following have been admitted Licentiates:—

Edmund Barry Denby, Dublin; Thos. Brown Cross, Scarborough; George Samuel Pollard, Norfolk; Thos. Benjamin Luscombe, Teddington; Edward Tongue Yeates, Balbriggan; Wm. Chas. Glasier Collins, London; James Newton, Manchester; Henry John Clarendon Godfrey, London; Roger David Delahaye Williams, Swansea; Gerald Cæsar Hawkins, Teignmouth; George Philip Longman, Southampton; Arthur Richard Rackham, Old Calton, Norfolk; Sydney Robert Lidiard, Hull.

ROYAL COLLEGE OF PHYSICIANS.—Dr. Hare Philipson, Newcastle-upon-Tyne, Professor of Medicine in the University of Durham, has been appointed to deliver the Bradshawe lecture, at the Royal College of Physicians, London, on August 18th.

NETLEY HOSPITAL.—It is stated that the drainage works in the neighbourhood of Netley Hospital have been discovered to be in such an unsatisfactory condition that a War Office inquiry is to be held.

LONDON HOSPITAL.—The Governors have decided to spend 8,000*l.* in building a new wing to the present Nurses' Home, to accommodate 100 nurses. The Baroness de Rothschild has given 10,000*l.* towards the funds of the hospital.

KING'S COLLEGE HOSPITAL.—This hospital is again in serious pecuniary difficulty. During the last six years the Committee have had to sell 48,000*l.* of stock in order to pay their way. Their last available stock will shortly have to be disposed of, and unless there is a large accession of funds, some of the wards will have to be closed.

THE ADULTERATION OF FOOD AND DRUGS.—A circular has just been issued by the Local Government Board, calling upon the various sanitary authorities throughout the country to take more efficient steps to enforce the provisions of the Sale of Food and Drugs Act, 1875.

NAVAL MEDICAL DEPARTMENT.—The following appointments have been made at the Admiralty:—John E. Penn, Surgeon, to the *Woodlark*; Henry J. Madders, M.D., Surgeon, to the *Duke of Wellington*; John L. Thomas, Surgeon, to the *Hector*; Francis M. Puddicombe, Surgeon, to the *Neptune*; Henry J. Gordon, Surgeon, to the *Shannon*; John H. Thomas, Surgeon, to the *Excellent*; James L. Smith, M.B., Surgeon, to the *Asia*; Frederick J. Lilly, Surgeon, to the *Indus*; George F. Dean, Surgeon, to the *Royal Adelaide*; George Welch, Surgeon, to the *Pembroke*.

INDIAN MEDICAL DEPARTMENT.—Bengal Medical Establishment: To be Deputy-Surgeon-General, Brigade Surgeon Alexander John Cowie. To be Brigade Surgeons, Surgeons Major William Roche Rice, M.D.; Henry Cayley; James Champion Penny, M.D. Surgeons to be Surgeons-Major, Alexander Crombie, M.D.; William Reed Murphy; Charles Henry Joubert; Edgar Geer Russell; John Scully, Geoffrey Craythorne Hall; Gopal Chunder Roy, M.D.; Adam Scott Reid; William Andrew Durnford Fasken, M.D.; Edward Lawrie; Joseph Wilson, M.D.; Edward Mulvany; John Manook Zorab; Russick Lall Dutt, M.D.; Girdharlál Ratantál Daphtary, M.D.; John Thomas Brownrigg Bookey; Alexander McGregor; James Young; Joshua Duke; Bankabehari Gupta; John McConaghey, M.D.; Edward Palmer; Alfred Henry Williams; Robert Andrew King Holmes, M.D.; John Edward Charnock Ferris. Madras Medical Establishment: Surgeons to be Surgeons-Major, Arthur Mudge Branfoot; Christopher John McNally, M.D.; William Edward Johnson, M.D.; Stanley Lockyer Dobie; George Frederick Bevan; Andrew Francis Dobson; Charles Little, M.D.; Thomas Mayne; John Crofton Lawrenson.

THE QUEEN'S COLLEGES (IRELAND) COMMISSION.—Having concluded their labours in the case of the Queen's College, Belfast, the Commissioner, Mr. R. P. Carton, Q.C., Chairman; Dr. George Johnstone Stoney, F.R.S.; the Rev. Gerald Molloy, D.D.; Dr. Jack, and Deputy-Surgeon-General John Marston—proceeded to Cork at the end of last week, and have since been engaged in holding an inquiry in the Examination Hall of the Queen's College near that city.

PROXY VOTING AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the Annual Meeting of the Fellows held on Saturday, May 31st, the following resolution was passed:—Resolved, "That it is to be regretted that the resolution of the College, passed without a division on the 4th June, 1883, recommending that the Fellows shall in future have the right of voting *in absentiâ*, by means of voting papers, for

the President, Vice-President, and Members of Council, has not been put into force; and that the incoming Council be requested to take immediate steps to have such alterations made in the Charter of the Royal College of Surgeons of Ireland as will enable the provincial and other Fellows of this College to vote at the election of the President, Vice-President, and Council by voting papers or otherwise."

THE ROYAL UNIVERSITY OF IRELAND.—At a largely attended meeting of the Senate of the Royal University of Ireland, held on Thursday, May 29th, the following were elected Fellows in the Department of the Natural Sciences:—Robert O. Cunningham, M.D., F.L.S., Professor of Natural History, Queen's College, Belfast; George Sigerson, M.D., F.L.S., Professor of Botany and Zoology, University College, Stephen's Green. The following examiners were re-appointed for one year:—In Medicine—Stephen M. M'Swiney, M.D. In Midwifery—John A. Byrne, M.D.; H. MacNaughton Jones, M.D. In Medical Jurisprudence—E. W. Davy, M.D. In Materia Medica—F. J. B. Quinlan, M.D.; J. Seaton Reid, M.D. The Senate also appointed Dr. Michael M'Hugh, one of the Examiners in Medical Jurisprudence, in succession to the late Dr. Matthias O'Keefe, of Cork. The Senate decided with regard to the Dr. Henry Hutchinson Stewart Scholarships, that one scholarship of the annual value of 50*l.*, tenable for three years, should be offered in the autumn of 1885 for competition among medical graduates of not more than two years' standing, for proficiency in mental diseases; and that a second medical scholarship of the annual value of 10*l.*, tenable for three years, should also be offered in the autumn of 1885, for competition in the subjects of the second examination in medicine. In order to be eligible, candidates must present themselves after the lapse of not more than one academical year from the time of passing the first examination in medicine.

THE IRISH MEDICAL ASSOCIATION.—The annual general meeting of this Incorporated Society, was held on Monday, the 2nd inst., at the Royal College of Surgeons in Ireland. Dr. Archibald H. Jacob, as President, occupied the chair. Dr. Chapman (hon. sec.), read the annual report of the Council, which alluded to the Medical Act Amendment Bill, the Union Officers' Superannuation Bill, the Labourers' (Ireland) Act, and the remuneration to which Medical Officers of Health were entitled for their services in connection therewith, the notification of infectious diseases, the payment of substitutes for prison surgeons during their temporary absence from duty on Crown or official business, and the exclusion of dispensary medical officers from the Commission of the Peace in Ireland, recently brought under the notice of the House of Commons by Mr. Sexton, M.P. Resolutions were adopted dealing with these various topics, and a very successful meeting was brought to a close by the taking of the second chair by the incoming President of the Association, Dr. W. D. Hemphill, of Clonmel. The annual dinner of the members took place in the evening, in the Albert Hall of the Royal College of Surgeons, Stephen's Green.

THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The forty-second annual meeting of this Society was held on Monday, June 2nd, in the Hall of the King and Queen's College of Physicians, Kildare Street, Dublin. Dr. William Moore, President of the College, took the chair at 4 p.m. Dr. J. W. Moore (hon. sec.) read the report of the Central Committee, which stated that the Society continued in a fairly satisfactory condition, and had during the past year been able to assist a very large number of applicants, although the amounts granted were necessarily very small. During the year ending May 31st, 1884, the sums that passed through the treasurer's hands amounted to 2,535*l.* Of this 1,104*l.* had been added to the funded property of the Society, in accordance with the wish of the donors. The sum of 1,230*l.* had been distributed, leaving a balance of 201*l.* in the treasurer's hands to meet the working expenses, &c. Of the sum distributed, 205*l.* was to medical men, 930*l.* to widows, and 95*l.* to orphans. Dr. Thomson (hon. treasurer) stated that the total assets of the Society for the past year amounted to 2,821*l.* 14*s.* 5*d.* The funded capital now amounted to 6,140*l.* 9*s.* 9*d.*, in stock of the Bank of Ireland, representing 20,640*l.*

INTERNATIONAL HEALTH EXHIBITION.—The Library Sub-Committee, of which Mr. J. L. Clifford Smith is secretary, have now held eleven meetings, and as a result of their labours they have succeeded in bringing together a valuable collection of books, periodicals, and government reports of many nations, bearing on the groups of the two great divisions, Health and Education, into which the Exhibition is divided. The number of books at present received is about 6,000, and these are now being catalogued by Mr. Carl A. Thimm, the librarian appointed by the Executive Council. It is proposed that the Library and Reading Room, which under certain regulations will be free to all visitors to the Exhibition, shall be opened on Monday, the 16th instant.

VOLUNTEER AMBULANCE WORK.—Sir Andrew Clark, M.D., presided, on the 5th instant, at a largely attended meeting of the students of the London Hospital, held for the purpose of forming a Volunteer Ambulance Company. Surgeon-Major Evatt gave an address, in which he pointed out that the only way to make the Army Medical Service efficient was to form a special corps of men experienced in medical science, and to do this they must have recourse to the medical students. It was unanimously resolved that a company entitled the "London Hospital Volunteer Ambulance Company" be formed, the members to be students of the hospital.

THE JAFFRAY SUBURBAN HOSPITAL, BIRMINGHAM.—The memorial stone of a new suburban hospital for chronic cases, presented to this town by Mr. John Jaffray, was laid on the 4th instant, at Erdington, near Birmingham, by Lord Leigh. The hospital building, designed by Mr. Yeoville Thomason, is in the Queen Anne style, and is built of red brick, with terra-cotta mouldings, string courses, cornices, and window archings. It will afford immediate accommodation for 50 patients, with a capacity for 50 more by adding wings to the rear. The hospital is two stories high, and the entrance is by a central porch facing a curvilinear carriage-drive and lawn. Upon the ground-floor there is an entrance-hall 17 feet by 13 feet, and beyond it, running right and left, a spacious main corridor leading to the wings.

CARDINAL MANNING ON PROVIDENT DISPENSARIES.—At the Annual Meeting of the Camden Provident Dispensary, held on Monday, Cardinal Manning, who occupied the chair, said that he was thoroughly convinced that the Provident Dispensary movement was a most wise, salutary, and solid one. It was founded upon a principle which has been well tested by experience and so certain in its results that he believed it ought to be applied far more widely than it yet had been—it was, in fact, nothing more than the principle of insurance, applied, not to life and property, but to the vicissitudes of human health and human sickness. There were three classes of persons in London. One was that class of persons who could and who ought to pay doctors' fees and doctors' bills; another was that class of persons who, through poverty, were quite unable to pay doctors' bills. But there was another class, which came between the two others, and this class of persons could just manage to pay the doctor, but with great privation to themselves. For this intermediate class the Provident Dispensary was established.

THE CONTAGIOUS DISEASES ACTS.—On Monday a deputation, representing all the towns in which the Contagious Diseases Acts were in force, waited upon Sir William Harcourt to present a memorial requesting that the provisions of the Acts which were withdrawn last year should again be put in operation. The memorial stated that the withdrawal of the metropolitan police had been followed by an increase of vice and disorder in the streets. Sir William Harcourt said, in reply, he was aware that to a great extent the opposition to the Acts had come from places that had not had experience of their working, while those places where the Acts had been in operation were in favour of their continuance. The Government had

endeavoured to make some provision for retaining the indirect advantages which had been derived under the Acts, and had introduced a Bill into the House of Lords which, if passed, would afford some means of restraining vice, and would directly arm the police with powers for the maintenance of decency and order in the streets.

WHEATLEY MEMORIAL FUND.—It is proposed to close this Fund at the end of the present month; the Treasurer will therefore be glad to receive all subscriptions before that date.

THE ANTI-VIVISECTION QUESTION IN AMERICA.—At the annual meeting of the Medical Society of the State of Philadelphia (*Philadelphia Medical News*, May 17th), Dr. Wen Mitchell, as chairman of a committee to which an appeal by the American Anti-Vivisection Society had been referred for consideration, mentioned its report. This pointed out the bad effects which the interference of a similar English society had produced by securing legislation hostile to scientific investigation. The law in England had put an end to physiological research. One eminent physician there, who has been investigating snake-poison there, has been obliged to give up his enquiries, and this in face of the fact that from 25,000 to 30,000 people are killed every year in India by snake-bites. The Indian Government has actually sent snake-poison to Philadelphia, and money also, to secure investigation, not being able to have such researches made in England. He appealed to all the members that efforts would be made to pass a law, and each of them ought to see that such a bill is defeated, and not have our great medical schools crippled as they are in England. At one of the meetings of the American Medical Association, resolutions were passed in favour of "Experimental Medicine," one which was unanimously adopted being in these words: "That in view of the attempts that have been, or may be, obstructed by restrictive legislation, in the progress of experimental medicine, this Association desires to express its earnest conviction that experimentation on animals is a most useful source of knowledge in medical science; that its direction and supervision can be properly entrusted only to members of the medical profession, and that its restriction or prohibition by law would inevitably retard the advancement of medical science, and the improvement of the medical art." There is a peculiar fitness in these resolutions at a meeting where one of the principal papers, that on "Gunshot Wounds," was based almost entirely on experimental work.

MORTALITY STATISTICS OF NEW YORK, FOR 1883.—Dr. Nagle communicates the following return to the *Medical Record* for April 26th. The deaths during 1883 amounted to 34,011, representing an annual death rate of 25·81 per 1,000 of the population, which was estimated in the middle of the year at 1,317,691. Of the 34,011 deaths, 9,011 were ascribed to zymotic diseases, 7,575 to constitutional diseases, 13,049 to local diseases, and 2,150 to developmental diseases, while 1,326 were due to violence. The deaths from some of the most prominent causes, are as follows: small-pox, 12; measles, 716; scarlatina, 744; diphtheria, 1,009; membranous croup, 644; whooping-cough, 327; erysipelas, 125; typhus fever, 15; typhoid fever 471; cerebro-spinal fever, 223; puerperal diseases, 416; diarrhœa in children under five years old, 2,897; diarrhœa (all ages), 3,398; inanition and want of breast-milk, 229; alcoholism, 222; cancer, 678; phthisis, 5,200; bronchitis, 1,435; pneumonia, 3,409; heart disease, 1,693; scrofula and marasmus, 831; hydrocephalus, meningitis, and encephalitis, 1,309; infantile convulsions, 514; sunstroke, 83; diseases of liver, 350; diseases of brain and nervous system, 2,810; diseases of kidney, 1,854; suicides, 161; drowning, 245; surgical operations, 39; deaths of persons of 70 years and upwards, 2,345; of children under one year, 8,671; under two years, 11,325, and under five years, 13,856. The total number of deaths taking place during the year in institutions, was 6,955; in tenement houses, 18,359, and in private houses, 7,770.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination of Local Surveyors and Inspectors of Nuisances held on the 5th and 6th instant, 23 candidates presented themselves. The Institute's Certificate of Competency to discharge the duties of Local Surveyors was awarded to W. H. Radford, J. B. Wilson, C. Gilby, W. Tattersall; and to discharge the duties of Inspectors of Nuisances, to R. Gibbs, G. W. Joblings, Kenneth Cameron, T. S. Ainge, T. Turner, R. Jeffery, J. Parker, J. Mallinson, W. A. Shaddrake, W. C. Beck, F. T. Poulson, J. Whyte, A. Suctliffe, C. J. Easton, and T. Haslam.

APPOINTMENTS.

ANDREWS, A. G., M.R.C.S.—House Surgeon to the London Hospital.
FLOOD, F. P., M.R.C.S.—Honorary Surgeon to the Leeds Public Dispensary, *vice* W. H. Brown, resigned.
GUNN, R. MARCUS, M.A., B.M. and M.S. Edin., F.R.C.S. Eng.—Ophthalmic Surgeon to the Great Northern Central Hospital.
LE CRONIER, J., M.D.—Consulting Surgeon to the Jersey General Dispensary.
MASON, WILLIAM, L.R.C.S. and L.R.C.P. Edin., and L.A.H. Dub.—Medical Officer to the Second District, St. Austell Union.
PHILIPPS, S. R., M.D.—Medical Superintendent of the Asylum, St. Ann's Heath, Chertsey.
SINCLAIR, JOHN, L.K. and Q.C.P. Ire., L.F.P. and S. Glas., and L.M.—Medical Officer to the Slaidburn District, Clitheroe Union, *vice* W. M. Seabrook, deceased.
RENDELL, H., M.B., C.M. Edin.—Assistant Physician to the North-Western Hospital, Haverstock Hill.
RICHARDS, THOMAS, M.B. Edin.—Honorary Physician to the Birmingham and Midland Free Hospital for Children, *vice* F. Marshall, M.B. Lond., resigned.
ROBERTSON, T. M., M.B., C.M. Edin.—House Surgeon to the Durham County Hospital, *vice* Melburn, resigned.
RUSSELL, R. H., M.R.C.S.—House Surgeon to the Salop Infirmary, Shrewsbury, *vice* W. Dowson, M.B., resigned.
WOOD, G. B., M.B., C.M. Edin.—Resident Medical Officer to the Jersey General Dispensary, *vice* Fredk. A. Hyne, M.R.C.S.

VACANCIES.

BOSCOMBE PROVIDENT INFIRMARY, BOURNEMOUTH.—Resident Medical Officer. Salary, £60 per annum, with board, &c. Candidates must be duly registered, and unmarried. Private practice prohibited. Applications, with copies of recent testimonials, to be sent to the Honorary Secretary, before June 28th.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD.—House Physician. Residence and attendance, with coals and gas, are provided, and an allowance at the rate of £80 per annum is made in lieu of board. Candidates must be registered under the Medical Act, and must not engage in private practice. Applications and testimonials to be sent to the Secretary, from whom further particulars may be obtained, by 12 noon, June 17th.

QUEEN'S COLLEGE BIRMINGHAM.—Professorship of Anatomy. Salary £262 10*s.* per annum. Applications with testimonials, to be sent to the Secretary, Joseph Lewis, 21, Paradise Street, Birmingham (from whom further particulars can be obtained), on or before June 30th.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY.—Honorary Physician. Candidates must be either F. or M.R.C.P. Lond., or Graduates in Medicine of one of the Universities of the United Kingdom. Applications, with diplomas and testimonials, to be addressed to the Medical Committee, at the Dispensary, 60, King Street, Golden Square, W., not later than June 25th; and candidates must attend personally at the Dispensary on June 26th, at 4.30 p.m.

TOWER HAMLETS DISPENSARY.—Medical Officer. (*For particulars see Advertisement.*)

TOWN OF CALCUTTA.—Health Officer. (*For particulars see Advertisement.*)

WEST LONDON HOSPITAL, HAMMERSMITH, W.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London, and not practising as apothecaries. They are requested to attend a meeting of the Medical Council on July 1st, at 3.30 o'clock p.m. The election will take place on July 7th. Applications and copies of testimonials to be sent to the Secretary not later than June 30th.

WILLITON UNION.—Medical Officer for the Stogumber District, in succession to Mr. Jonathan Crocker, resigned. Area, 14,003 acres. Population, 3,011. Salary, £30 per annum.

WHITBY UNION.—Medical Officer for the Fylingdales District, in succession to Mr. T. Finley, whose term of office has expired. Area, 13,010 acres. Population, 1,448. Salary, £30 per annum.

YORK COUNTY HOSPITAL.—Assistant House Surgeon. Salary, £50 per annum, with board and residence. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons in the United Kingdom, registered under the Medical Act, and unmarried. Applications, stating age, accompanied by testimonials, to be sent to Secretary's Office, 5, New Street, York, on or before June 21st.

DEATHS.

DICKSON, J. B., Inspector-General of Hospitals, retired, Bengal Medical Service, at the Albany, Piccadilly, on June 11th, aged 78.
GAMBLE, R., Deputy Inspector-General, M.A., M.D., at Brompton, on May 28th.
LLOYD, R. R., M.R.C.S., at Boroughfield, St. Albans, on June 1st, aged 41.
ROGERS, Dr. H., F.R.C.S., at Boursault, Curepipe, Mauritius, on April 16th, aged 48.
STRANGE, G. H., F.R.C.S., at Lyonsdown, New Barnet, on June 2nd, aged 64.
WALTER, JAMES KING, Surgeon-Major, retired list, Indian Army, at Mansfield House, South Hampstead, on May 28th.
WODSWORTH, C. G., Staff Surgeon, R.N., at the Royal Naval Hospital, Haslar, on May 23rd.

NOTES, QUERIES, AND REPLIES.

Fellow Elect.—You cannot record your vote at the Annual Election of Fellows into the Council of the College of Surgeons until you have signed the bye-laws. Write at once to the Secretary, who will let you know at what meeting of the Council you can attend for that purpose.

Dr. H. Sorley, Wanganui, New Zealand.—Letter and enclosure received with thanks.

COMMUNICATIONS RECEIVED—

Dr. James Copland, New Zealand; The Hon. Secretary of the West London Medico-Chirurgical Society, London; The Secretary of the Belgravia Dairy Company (Limited), London; Dr. J. Pedlow, Weymouth; Dr. Hare Philipson, Newcastle-on-Tyne; The Secretary of the International Health Exhibition, London; Mr. Lawson Tait, Birmingham; Mr. H. C. Burdett, London; Mr. St. Vincent Mercier, London; Dr. J. W. Langmore, London; Mr. T. J. Barnardo, London; The Secretary of the Apothecaries' Society, London; Dr. Charles West, London; The Chairman of the Vestry of Hampstead, London; Dr. G. E. Herman, London; The Sanitary Commissioner of the Punjaub, Lahore; Mr. T. M. Stone, Wimbledon; The Editor of the Sanitary Engineer, New York; The Registrar-General for Scotland, Edinburgh; The Secretary of the Society of Medical Officers of Health, London; Dr. C. J. Hare, London; Dr. Norman Kerr, London; The Secretary of the Sanitary Institute of Great Britain; Mr. John Tweedy, London; Dr. Willoughby, London; Our Dublin Correspondent; Dr. Shelly, Hertford; Messrs. H. R. Williams & Co., London; The Secretary of the University College, London; Inspector-General of Chinese Imperial Maritime Customs, London; The Secretary of the Wheatley Memorial Fund, London; Mr. G. W. Hind, London; Dr. Alexander Meighan, Glasgow.

BOOKS RECEIVED—

Analysen-Tabellen der gebräuchlichsten Mineralbrunnen und kohlensauren Heilwasser—The "J. E. M." Guide to Davos-Platz, by J. E. Muddock—Notes on Books, by Messrs. Longmans & Co.—On Visceral Neuroses, by T. Clifford Allbutt, M.A., M.D.—Report on the Health of the Borough of Gateshead, during the year 1883—The Sanitary Past, Present, and Future of Calcutta—Edinburgh University Tercentenary Festival, 1884—Sleep-Walking and Hypnotism, by D. Hack Tuke, M.D., LL.D.—Recent Materia Medica, by F. H. Lescher, F.C.S.—Hospital Construction and Management. Part II. By F. J. Mouat, M.D., F.R.C.S., and H. Saxon Snell—Wharton and Stille's Medical Jurisprudence. Vol. ii.—The Continued Fevers of Great Britain, by Chas. Murchison, M.D., LL.D., F.R.S.—The House of Lords, by Sir John Bennett—Reports of the Medical Officers to the Chinese Imperial Maritime Customs Service, from 1871 to 1882—Influence of Constant Use of High-heeled French Shoes upon the Female Form, &c., by S. C. Busey, M.D.—Lehrbuch der Auscultation und Percussion, von Dr. C. Gerhardt—Mittheilungen aus der Chirurgischen Klinik zu Kiel, von Dr. Friedrich Esmarch—The Action of Certain Remedies in the Treatment of Hygro-Neuralgia, &c.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Révue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Louisville Medical News—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medicin—Philadelphia Medical News—Le Progrès Médical—New York Medical Journal—Students' Journal and Hospital Gazette—New York Medical Record—The Edinburgh Clinical and Pathological Journal—The Philadelphia Medical Times—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—Maryland Medical Journal—Weekblad—The Otago Daily Times, April 5th—Société Médicale—The American Psychological Journal—The Medical Bulletin—The Australian Medical Gazette—Nice-Médical—Revista de Medicina—Journal of Cutaneous and Venereal Diseases—Revista Internazionale—The Indian Medical Gazette—The Canada Lancet—Night and Day—Popular Science News—The Western Medical Reporter—Scienze Mediche—The Practitioner.

APPOINTMENTS FOR THE WEEK.

Friday, June 13 (*this day*).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Royal College of Surgeons of England, 4 p.m.—Professor Sir Henry Thompson will deliver his Second Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

Royal Institution, 8 p.m.—Prof. Dewar, "Researches on Liquefied Gases."

Saturday, June 14.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, June 16.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Royal College of Surgeons of England, 4 p.m.—Professor Sir Henry Thompson will deliver his Third Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

Tuesday, June 17.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Wednesday, June 18.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Royal College of Surgeons of England, 4 p.m.—Professor Sir Henry Thompson will deliver his Fourth Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

Thursday, June 19.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, June 20.

Royal College of Surgeons of England, 4 p.m.—Professor Sir Henry Thompson will deliver his Fifth Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

ON INDUSTRIAL DISEASES.[1]

By J. S. BRISTOWE, M.D., F.R.S.,

Physician to St. Thomas's Hospital and Medical Officer of Health for Camberwell.

THE investigation of the causes of disease is a subject which has ever engaged, and still engages, the choicest intellects in the profession of medicine. For not only does it present the highest scientific fascination, but it is fully recognised that it is in the discovery of the causes of disease that our best hopes of dealing successfully with diseases, either in curing, in mitigating, or in preventing them, reside. When it was proved that scurvy, that direful scourge of sailors in by-gone times, was due simply to deprivation of vegetable food, both the means of preventing it and the method of curing it became obvious. When once it was established that certain fatal infectious diseases of the lower animals were due to specific vegetable organisms, which could be separated from the tissues of the body and cultivated apart from them, the possibility naturally suggested itself that by appropriate methods of cultivation they might be so far robbed of their virulence as to impart or inoculate milder forms of disease, which (in accordance with the analogies afforded by the relation of cow-pox to small-pox, and the protection which one attack of any infectious fever generally gives against subsequent attacks of the same disease) should hold their subjects harmless for the future. I need scarcely remind you of the brilliant results which, by the skilful pursuit of this idea, M. Pasteur has achieved in relation to the anthrax fever of cattle and chicken cholera, or remark on the promise which they give that other human diseases besides small-pox shall some day be robbed of much of their loathsomeness and danger. When also it became apparent that septicæmia and pyæmia, the frequent causes of death after accidents, after operations, and in the lying-in room, were due alone to the inoculation of the system through the wounded surfaces with the septic organisms of bacteria, which abound everywhere and are the agents in putrefactive processes, the need of absolute cleanliness and of the most careful protection of susceptible parts from accidental inoculation from without followed as a corollary. And the introduction of so-called Listerism into surgical practice has deprived the gravest operations of much of their danger, and has rendered possible the frequent successful performance of operations which formerly one scarcely dared to attempt.

As civilisation has advanced, and manufacturing and other processes have developed in order to meet the growing wants of mankind, dangers formerly unknown have arisen, accidents of special kinds have become common, and diseases new to our nosology have sprung

[1] Read at a Conference at the International Health Exhibition on Wednesday, June 11th, 1884.

up amongst us—accidents and diseases dependent on the new conditions under which, in certain circumstances, men have found themselves placed. I do not, of course, mean to say that civilisation has tended to increase sickness and shorten life, for the reverse of this is known to be the fact. No doubt many causes of disease and injury to which our savage, or less civilised, ancestors were exposed, have wholly, or in part, ceased to be operative, and by so much have we been the gainers; but, none the less, new and often unsuspected sources of mischief have, from to time, appeared in association with conditions, mainly beneficial, determined by our progress in art, in science, and in luxury.

Among the dangers here referred to must be included: first, accidental injuries, such as mining accidents, accidents caused by machinery, accidents due to the ignition of explosive compounds, and the like; second, the dangers arising from the temptations to which special occupations expose the persons engaged in them, such as those of alcoholic intemperance incidental to pot-men and commercial travellers; and, third, diseases due to poisonous or other influences incidental to certain occupations, and which can only be escaped, if escaped at all, by the adoption of special precautionary measures. It is this last subject with which alone I have to deal on the present occasion.

One of the most interesting groups of industrial diseases is that in which injurious effects arise from the slow action of metallic or other inorganic substances, or their derivatives upon the system.

Chronic Lead-poisoning.

Metallic lead is probably inert; and even its salts, though generally regarded as poisons, may, for the most part, be taken even in large quantities without material injury to the taker. It is very different, however, with respect to the salts of lead habitually received into the system, even in minute proportion. It would be difficult to enumerate all the conditions under which chronic lead-poisoning is apt to occur. All those who have to do with metallic lead, such as lead-miners, plumbers, type-founders, and manufacturers of lead toys, occasionally suffer. All persons concerned in making glass, in glazing pottery and the like, in which operations the oxides of lead are employed, are liable to become affected. But the chief sufferers are those who manufacture, or employ in their work, the carbonate of lead; especially therefore, painters, plumbers, glaziers, glazed-card manufacturers and lacquerers. It is important to note, however, that lead-poisoning is not limited to operatives in lead, but that owing to the extensive employment of this metal, and of its derivatives, the general public are by no means free from danger; and that isolated cases, or groups of cases, of plumbism, referable sometimes to the drinking of water stored in lead cisterns, sometimes to the use of hair-washes or cosmetics containing lead, sometimes even to the long-continued employment of lead as a medicine, and to other sources of contamination which need not now be specified, are often brought under the notice of medical men.

The symptoms of chronic lead-poisoning are for the most part very striking, and generally quite unmistakable. The most common, and on the whole the most important, are a peculiar form of affection of the bowels, and a peculiar form of paralysis. Lead colic (as it is termed) is usually the earlier in its advent. It is characterised by intense griping abdominal pain, coming on in paroxysms, and associated with hardness and retraction of the abdominal muscles, nausea or sickness, and almost insuperable constipation. Lead palsy, in its simplest form, attacks those muscles of the forearm which extend the wrist, the thumb, and the first joints of the other four fingers, so that, when the forearm is held out prone the hand drops powerless at the wrist, and the fingers droop so as to form nearly a right angle with the rest of the hand. This condition is known as "dropped wrist." Further, the affected muscles are tender and irritable, and rapidly waste. The palsy, however, is not in all cases confined to these muscles. Sometimes the upper arm suffers as well as the forearm; sometimes the muscles of the legs are implicated; and occasionally indeed the muscles of the trunk, including those of respiration, become involved. But, besides these chief consequences of chronic plumbism, other phenomena due to the same causes are observed. A peculiar form of cachexia, characterised by anæmia or bloodlessness, a sallow or earthy tint of the skin, derangement of the digestive organs and debility, is generally present in a greater or less degree; and in connection therewith may be mentioned the fact of the occurrence of a characteristic blue line along the margins of the gums at the junction with the teeth. Occasionally also, late in the progress of the disease, blindness, epileptiform fits, dementia, or some other form of madness makes its appearance. A curious but very important fact was observed by Dr. Garrod some years ago, and its truth has been confirmed by subsequent observers, namely, that there is a remarkable relation between gout and chronic lead-poisoning; that the victims of the latter affection become disproportionately liable to gout, and that persons of gouty tendency are specially prone to suffer from exposure to lead.

The immediate cause of the various phenomena above described is the entrance of lead in some one of its forms into the system; its deposition in the tissues; and its specific deleterious action on the organs which chiefly suffer. The poison gains access either by the respiratory organs, owing to the inhalation of vapour or dust; or by the stomach, in consequence of the impregnation of food or drink; or, possibly also, in certain cases, by cutaneous absorption.

In most instances the injurious effects of lead are readily recovered from if the case be taken early, and if the sufferer give up the employment which exposed him to danger. If, however, he persist in exposing himself, either the colic may prove fatal, or the paralysis becomes established and spreads; and finally, he dies either from the effects of cachexia, from extension of paralysis to vital parts, or from the supervention of symptoms of cerebral disease.

It is probably impossible that workers with at any rate some forms of lead should be rendered wholly free from liability to lead-poisoning. But it is clear that much may be done to minimise danger. "The first principles in lead-works are the inculcation of cleanliness; avoiding eating with unwashed hands, or in working clothes, or in workshops; moist-grinding; free ventilation; precautions against dust rising, or wearing flannel respirators when this is unavoidable; with occasional doses of sulphate of magnesia, acidulated with sulphuric acid." Similar precautionary measures should of course be taken by painters, and by all who are habitually exposed. It is seriously worth while for those who inherit a tendency to gout to consider twice before entering upon occupations which expose those who follow them to lead-poisoning.

Chronic Copper Poisoning.

Pure copper, like pure lead, is probably inert. But the salts of this metal are much more poisonous than those of lead; and acute poisoning by them is not only characteristic in its symptoms, but liable to end fatally. It is somewhat curious, therefore, that characteristic poisonous effects from the long-continued absorption of cuprous compounds are not nearly so common as those due to lead, and indeed that by some their occurrence is

denied. It is certain that copper salts gain entrance into the system by the same routes and methods as lead salts, that they become deposited in the tissues, and that a characteristic greenish or purplish line, somewhat resembling that due to lead, is apt to appear at the edge of the gums. But here all positive knowledge ceases. It is said, and seems not improbable, that workers exposed to the fumes or dust of cuprous salts are liable to suffer from nausea, sickness, diarrhœa, and other symptoms of gastro-intestinal irritation; and there is good evidence that brass-founders are subject to periodical febrile attacks in which colic or intestinal disturbance is followed by rigors, and to which the name of "brass-founder's ague" has been given. But it is held that the symptoms are due, not to copper, but to the zinc or arsenic which is combined with the copper. The subject of chronic copper poisoning derives a special interest from the fact that copper is—or, perhaps I should rather say, has often been—designedly mixed with pickles and preserved vegetables to give them colour. I believe that no clear evidence has yet been adduced of the injurious effect of copper taken under such circumstances. Nevertheless, it must always be borne in mind that copper salts are poisons; that, if they be taken accidentally in excess, acute and even dangerous symptoms may result; and that hence it is probably as important, in the case of copper as in that of lead, that those who are exposed to danger should adopt the precautions of cleanliness and the like which have already been specified.

Chronic Arsenical Poisoning

Is not uncommon in consequence of the inhalation of arsenical vapours or arsenical dust. "Those who are chiefly exposed to this form of poisoning are persons employed in the manufacture of pigments, paper-hangers and decorators, artificial flower manufacturers, milliners, persons exposed to the fumes of heated metals, particularly zinc and brass, manufacturers of dyes, and leather-dressers." Further, persons living in rooms papered with arsenical paper are very liable to suffer. The substance to which chronic poisoning is mainly due is arsenite of copper, commonly known as Scheele's or emerald green, which was formerly largely used as a pigment, and is still thus used to some extent. Dr. Guy, in the year 1862, investigated the effects of this preparation as they were shown in the industries in which they were chiefly employed, and ascertained that it was mainly in connection with the colouring of paper and of artificial leaves, fruits, and flowers that chronic poisoning occurred. The main symptoms are congestion or inflammation of the conjunctivæ, with intolerance of light and œdema of the eyelids; a sense of heat and tightness in the throat; a feeling of heat and pain in the pit of the stomach; together with more or less feverishness, thirst, loss of appetite, and nausea. Following on these or associated with them may be developed salivation, sickness and diarrhœa, dryness of skin, with erythematous or eczematous eruptions, œdema of the extremities, nervous disturbance, feebleness and tremor of the limbs, gradual emaciation, and finally death. The disease, however, rarely proves fatal, inasmuch as its nature is generally recognised long before the symptoms have become dangerous, and the proper means of arresting it have been adopted in time. Yet occasionally the symptoms (which are liable to variation) are misleading; and if at the same time the source of poisoning be not detected, serious consequences are likely to ensue. It may be added that cutaneous symptoms are among the earliest and most common of the effects of arsenic, being produced by local irritation, and that, although not generally dangerous, they are a source of infinite discomfort and annoyance. There seems to be no doubt, on the other hand, that persons may readily accustom themselves to the habitual use of arsenic in increasing quantities, until so much is taken at a time as would poison any ordinary person, and that under such circumstances, not only are there no symptoms of poisoning, but the health and strength and complexion are all improved. The chief evidence in relation to this subject (and the evidence appears to be unimpeachable) comes from the arsenic works of Styria and some parts of Austria. No doubt amongst arsenical workers cleanliness is of great importance; not improbably improvements in process of manufacture have been and may be made beneficial to the workpeople; but as a general rule those who are specially liable to suffer and those whose exposure is only accidental will do wisely to escape danger by its avoidance.

Chronic Mercurial Poisoning.

The per-salts of mercury, like all preparations of arsenic, are very potent irritant poisons. And all salts of mercury, after having been taken for a longer or shorter time, produce characteristic effects, the most prominent of which are salivation, swelling and tenderness of the gums, loosening of the teeth, and fœtor of breath, in association, with more or less cachexia, and disturbance of the digestive organs. Further, ulceration and gangrene of the parts about the mouth are apt to ensue. But chronic poisoning occurs among the workpeople who are habitually exposed to the vapour or dust of mercury, or its salts, especially, therefore, amongst those employed in quicksilver, mining, water-gilders, the manufacturers of looking-glasses, barometers and thermometers, furriers and persons engaged in the packing of furs, which have been brushed over with solution of nitrate of mercury. Yet, curiously although such persons may present the symptoms commonly observed in patients who have been subjected to mercurial treatment, for the most part their symptoms are of quite a different character, being of a paralytic nature, and referable to the nervous and muscular systems. The condition is, in fact, known by the name of metallic, or mercurial, tremor. The first signs of its presence are:—a general tremulousness of the hands and arms, which come on gradually; numbness, and tingling in the hands and feet; and occasional pains in some of the joints. Such symptoms are common amongst workpeople exposed to the vapour of mercury, and may continue for years without materially interfering with their capacity for work or their general health. But, sooner or later, they tend to get aggravated; they not only become more violent, but gradually extend to all parts of the muscular system, so as to involve at length hands, arms, legs, head and neck (including the muscles of expression, speech, and swallowing), and trunk, with the muscles of respiration. Then the violent trembling of the hands and arms renders the sufferer incapable of using these organs; he cannot lift a glass of water to his lips, or feed, or dress himself; the agitation of his legs becomes so great that he is unable to walk without being supported on either side; the convulsive action of the muscles of the head and neck causes constant tremulous movements of these parts, while that of the muscles of expression reveals itself in grimaces, and that of the lips, tongue, and muscles of mastication causes tremulous and indistinct utterance, and difficulty in chewing; the involvment of the respiratory muscles induces dyspnœa. These convulsive movements are generally absent when the patient is making no muscular effort; but sooner or later they do not wholly cease even when the patient is in bed or asleep. And at length, possibly, as in the later periods of lead palsy, vertigo, headache, loss of memory, deli-

rium, epilepsy, or distinct paralysis comes on. It is remarkable that the symptoms above enumerated are by no means necessarily associated with other indications of mercurial poisoning, or signs of ill-health. But such symptoms sometimes attend the onset of the palsy, or arise during its progress; and probably always towards the end the patient gets sallow, emaciated and weak, loses appetite, and presents a general failure in his corporeal functions.

In order to prevent the occurrence of mercurial tremor the same rules with respect to ventilation and cleanliness as have been laid down for workers in lead should, of course, be followed. It is probable, too, that in some of the occupations which entail exposure, modification of process might be advantageously introduced. But it is quite certain that all persons who are habitually exposed, as some of the workers must be, to mercurial fumes, are liable to suffer. Fortunately for them, if they be treated early, and especially if they give up their dangerous occupations, a cure is probably always possible.

Chronic Phosphorus Poisoning.

Shortly after the introduction of phosphorus in the manufacture of matches, it began to be observed that a peculiar affection of the jaw was apt to come on in those who were engaged in the match factories. The first person to call attention to the subject was Dr. F. W. Lorinser, of Vienna, who in 1845 published an account of 22 cases of jaw disease, of which the earliest had occurred as far back as 1839. In 1847 Drs. Von Bibra and Geist published jointly an elaborate work on the subject, in which they gave an analysis of 68 cases, which up to that time had occurred in Germany. During the next few years many cases of the disease were recorded in England, France, and other countries, and several works on the subject were published. And in the year 1862 it fell to my lot to make, for the Medical Officer of the Privy Council, an exhaustive report on the subject, so far as it related to the phosphorus industry in England. I ascertained at that time that at least 61 cases of the disease had happened in this country; and that, without exception, all the cases had occurred amongst the operatives in match factories.

The disease consists in a slowly progressive inflammation of the periosteum of the under or upper jaw, or both, resulting sooner or later in the necrosis or death of the bone, which ultimately (if the patient survive so long) is thrown off, or comes away. The patient, in fact, loses the whole, or a part of the upper or lower jaw, as the case may be; and, besides incurring all the distress and danger which attend a long-continued, foul and enfeebling disease, emerges from his malady permanently, and often hideously deformed. I quote the following account of the affection from my report just referred to:—"The disease, it was noticed, began usually with aching in one of the teeth. At first, this was probably mistaken for an ordinary tooth-ache, and would indeed at times intermit. Sooner or later, however, recurrence of pain necessitated the extraction of the tooth, and the pain and annoyance for a time probably ceased. The wound in the gum, however, was found not to heal; offensive matter began to ooze from it, and ere long a portion of the alveolus became exposed. Occasionally the portion of bone thus denuded came away, bringing with it, perhaps, one or two of the neighbouring teeth, and the disease made no further progress. More frequently, however, the disease continued to spread, and, sometimes slowly, sometimes rapidly, more and more of the jaw-bone became denuded; the gums grew spongy and retreated from the alveoli, the teeth got loose and fell out, the fetid suppuration became more and more copious, the soft parts around grew swollen, tender and infiltrated, and often the seat of sinuses. And thus the disease continued to progress, till in the course of six months, a year, two years—it might be even five or six years—the patient sank from debility, or from phthisis, or from some other consequence of the local affection; or, having lost piece-meal, or in the mass, large portions, one-half, or even the whole of the upper or lower jaw, returned to his original state of good health, but the victim of a shocking and permanent deformity. During the earlier and more acute stages of the disease, constitutional disturbance, as might be expected, generally showed itself, indicated by febrile symptoms, loss of appetite, thirst, constipation, a sallow, pasty condition of the skin, and these were often associated with intense pain in the affected parts, and consequent sleeplessness. After a while, however (especially in cases that were tending to a favourable issue), pain and constitutional symptoms diminished, and the patient sometimes recovered the aspect of health, even while necrosis of the jaw was still progressing."

The disease occurred only amongst such as were largely exposed to the fumes of phosphorus, and was generally confined to those whose duty it was to dip the matches in the melted phosphorus paste. Occasionally, however, in crowded and ill-ventilated factories, others besides dippers were affected. It was clear (although that point has been disputed, and was not originally held) that the disease was due to the local influence of the phosphorous fumes, and not to constitutional contamination; for there was no evidence whatever that persons exposed suffered in the slightest degree in their general health; and indeed the subjects of the phosphorous necrosis were always in good bodily health, until they began to suffer from the injurious effects of their local malady. It was thought by many that the disease only attacked those who had decayed teeth, and that the phosphorus exerted its immediate influence upon them. This view, however, was not entirely confirmed by observation. It seems, indeed, that, though the malady affected in largest proportion those with carious teeth, the special condition which made persons liable to attack was soreness or ulceration of gum, no matter how produced.

In speaking of phosphorus necrosis, I have spoken mainly in the past tense, because, although not improbably, it even now prevails in some parts of the world, and especially in overcrowded, ill-ventilated factories in which the cheaper forms of matches are still manufactured, I believe that owing to the precautionary measures which have been adopted, and especially to the large use of the amorphous phosphorus, which yields no injurious vapour, the disease has largely, if not entirely, disappeared from among us. At any rate, very little has been heard about it for some years, and no case has come under my own observation.

Effects of Irritants applied to the Skin.

From the group of affections just considered, due to the poisonous action of certain mineral substances, to which in various industrial processes workmen become exposed, I pass on to give a brief consideration to the direct irritating influence on the skin of certain matters which are generally regarded as inert, and in fact generally are inert. It is well known that grocers, bakers, washerwomen and others, are liable to inflammatory affections of the skin, mainly and primarily of the hands, commonly known as grocer's itch, baker's itch, washerwomen's itch and so on. These affections are not itch in the proper acceptation of the term, but eczema, or a variety of eczema, induced and kept up by the irritant effects in the first case of sugar, in the second of flour, and in the last of soap, or rather of imperfectly made soap or of the soda which is so constantly employed in washing. Most persons are acquainted with the fact that some delicate and irrit-

able skins are readily irritated and inflamed by even the purest soaps. Common soaps, in which alkali is in excess, or the ingredients are insufficiently mixed, are injurious to most skins. It is a phenomenon of the same kind which washerwomen at times present; but the simple irritation of the skin tends to become, in consequence of the constant use of soap and soda, a veritable inflammation of the skin, and before long results in vesication and excoriation. The above eruptions, which present little difference among themselves, are of course readily cured by the avoidance of the conditions to which they are due.

In relation with this subject I may briefly refer to two other kinds of skin disease which are determined by occupation, the one the so-called "*chimney-sweeper's cancer*," the other a somewhat analogous disease, sometimes termed, though inappropriately termed, *verruca necrogenica*, or, if one may translate the name into English, *the dissector's wart*.

In former days, when chimney-sweepers used to go up chimneys, and their occupation led to their being constantly begrimed with soot, it was observed that they not unfrequently became the subjects of a form of cancer of the skin now commonly known as epithelial cancer or epithelioma. This disease is not special to chimney-sweepers, but in them it affected parts of the body which are not usually attacked in other persons; and the relative frequency with which it was observed in them acquired for it from the distinguished surgeons who first observed it, the distinctive name which we have quoted. I believe that what was called chimney-sweeper's cancer is very rarely met with now, and that its infrequency is due to the practical discontinuance of the conditions which were believed to engender it.

The dissector's wart is special to persons whose hands are constantly employed in the dissection or cutting up of dead bodies. Hence it is common among persons engaged in pathological researches, in those who frequent dissecting rooms, and I believe also it is met with among butchers and knackers. It is a curious kind of circumscribed thickening of the knuckles, associated with the formation of pits or excavations, and the accumulation of crusts or scabs on the surface. The affection slowly spreads, and, so far as I know, never dies out, unless either it be destroyed by strong caustic applications, or the sufferer renounce the duties which first excited it.

Effects of Irritants applied to the Lungs.

But the irritant effects of matters, which are not poisonous, are not limited to the skin. Occupations which habitually expose the workmen to the inhalation of abundant solid particles, that are incapable of solution or removal by the animal tissues or secretions, in many cases induce chronic diseases of the lungs, which are known as the asthmas or consumptions of the several occupations referred to, and tend very materially to shorten life among those engaged in them. Workers in coal mines and in copper mines, grinders, millstone makers, and flax-dressers, are perhaps especially liable to suffer from such causes. It is marvellous how tolerant the bronchial tubes and lungs are of foreign particles which are drawn into them with the breath. Wherever smoke impregnates the atmosphere, as in London and other manufacturing towns, its particles are conveyed in greater or less abundance into the lungs; whence some are expelled with the expectoration, which presents, consequently, a slaty or black appearance, while some get absorbed, and becoming deposited in the tissues of the lungs, produce in them that black mottling which increases with advancing years, and is well known to pathologists. Yet as a general rule, the soot-studded organs remain practically healthy, and no clinical evidences of pulmonary disease manifest themselves. The same remarks doubtless apply to the inhalation of the silicious particles of ordinary dust. The effects are different, however, when such matters are inhaled in large excess. In coal-miners the lungs occasionally become almost as black as coal; and the excessive accumulation of carbonaceous matter induces a chronic inflammatory condition of the organs, associated with induration, and occasionally with the breaking down of the pulmonary texture. Among copper-miners something of the same kind occurs; but in this case the sooty matter is associated with a large proportion of silicious particles, which are far more irritating than simple carbon, and more rapidly induce chronic inflammatory changes than it. In grinders and mill-stone makers, the inhaled particles are mainly stony or silicious particles, and the injurious effects ensue with greater rapidity. Among flax-dressers the pulmonary mischief is of the same kind. It appears, indeed, that the particles which are absorbed exert no specific influence; that whether they be carbonaceous, silicious, or of any other nature, their effects are simply irritative, and to produce chronic inflammation or fibroid change; and that the only appreciable distinctive characters are such as are due to the quality of the particles imbedded in the lungs, and to the greater or less rapidity of progress of the disease. The symptoms under which the sufferers labour have some resemblance to those of chronic phthisis, some to those of chronic bronchitis and emphysema, for either of which they may well be mistaken. They consist in gradually increasing shortness of breath, lividity of surface, feebleness of circulation, and cough, with more or less abundant expectoration; to which, at a later period, general dropsy and hæmoptysis may be superadded. There is generally a total, or almost total, absence of fever. The only methods, so far as I know, by which the irritative diseases of the lungs, just considered, can be lessened or prevented, are by providing good ventilation, and (when possible) by adopting methods to prevent the diffusion of particles or dust in the atmosphere which the workmen have to breathe. It is obvious, too, that since the diseases are insidious in their progress, and increase in proportion as the inhaled particles accumulate, it would be well for persons who present early traces of them to seek at once some other kind of employment. Much of our knowledge of the subject just considered is due to the labours of Dr. Headlam Greenhow.

Phthisis in connection with Sedentary Work and Defective Ventilation.

But quite apart from the inhalation of solid particles which irritate the lungs into disease, it is certain that many occupations tend to the production of pulmonary phthisis and fatal bronchial affections. I will quote the remarks made by Mr. Simon, in reference to information which his inspectors had obtained concerning the lives of straw-plaiters, lace-makers and glovers at Berkhampstead, Tring, Towcester, Newport Pagnell, Nottingham, Radford, Barford and Yeovil; the lives of watch-makers at Coventry; the lives of button-makers, jewellers, and various knick-knack makers at Birmingham and Sheffield; the lives of stocking-makers at Lincoln, Nottingham, Radford, Basford and Hinckley; the lives of pottery artisans, especially of the decorators of earthenware, at Stoke and Wolstanton; and the lives of factory operatives employed on cotton, silk, flax, and wool at Preston, Leeds, Bradford, Pateley Bridge, Macclesfield, Leek, Stroud, Melksham, Coventry, and Blackburn; "The concurrent testimony," he says, "of these most various illustrations is —that commonly, where many persons are employed together at any indoor industry, the ventilation of the work-place is likely to be so bad as to convert the employment, which perhaps is not in its own nature of

*

hurtful tendency, into an employment seriously dangerous to health. Here lies the explanation of a fact most deplorable for the working classes of our country—that, *in proportion as the people of a district are attracted to any collective indoor occupation, in such proportion, other things being equal, the district death-rate by lung-diseases will be increased.* For the bad ventilation which, as a rule, belongs to the place of employment, tends to develop among the workpeople a large excess of phthisis, and probably also some excess of other fatal lung disease." It was further proved, by evidence obtained by Dr. Edward Smith in reference to printers and tailors, and by Dr. Ord in reference to dress-makers, and published in the appendix to the report from which I have been quoting, that the mortality from pulmonary diseases was also very high among them. Dress-makers appeared to suffer least; but printers, and above all tailors, whose hours of work were much prolonged, and whose work was largely conducted in over-crowded ill-ventilated apartments or work-shops, suffered severely. The document from which I quote appeared just twenty years ago. It is probable that in many cases much sanitary improvement has taken place since then.

Spread of Infectious Fevers in connection with certain Industries.

There are a few occupations which render those who carry them on liable to contract infectious diseases accidentally brought to them by what are technically termed *fomites*, that is, by articles which have become impregnated with, or contaminated by, the virus or poison of the diseases in question.

Seeing how virulent the contagia of most infectious diseases are; how they cling to clothing, to wall-papers, to filth, and even to most things brought into relation with them whose surfaces are porous or rough; how such diseases are apt to be conveyed by healthy persons passing between the sick and those who are susceptible, by the transmission of articles of apparel, by books, by letters, by milk, and other articles of food, and in many ways, some of which are scarcely suspected; it seemed reasonable to believe that the spread of disease might be due in no inconsiderable degree to rags collected here, and imported, for the purposes of paper-making. In the year 1865, I made an extensive enquiry into the question of the spread of infectious diseases by rags, and more especially among the work-people engaged in paper-making. The result was to a considerable extent reassuring; for it appeared in the first place that no disease special to foreign countries had ever been introduced amongst them by the agency of foreign rags, and that as regards native rags the only disease that was ever spread by them was small-pox, and this only rarely. A recent enquiry by Dr. Parsons has, in the main, confirmed the conclusion at which I had arrived, but shows, I think, that small-pox is somewhat more frequently spread by rags than my own enquiries had led me to believe. There are many reasons for the comparative safety of the rag trade which I need not now discuss.

But the most interesting facts, in relation to the spread of infectious disease by the use of materials impregnated with morbific virus, are those which have been collected during the last few years, in reference to the affection known in Bradford as the "Wool-sorter's disease." I may state at once that this has been ascertained to be the anthrax fever, or splenic fever of cattle—a very fatal bovine disease, which prevails in many parts of the Continent, and also in Asia and America, and is known to spread readily from cattle to other animals, and to man. Anthrax fever is one of the few diseases which have been clearly proved to depend on the entrance into the system, and the growth in it, of specific forms of living vegetable organisms, or bacteria; and it will, perhaps, be recollected that it is one of the affections the virus of which M. Pasteur claims to have attenuated, or rendered less virulent by cultivation, so that by inoculation of animals with the cultivated products a mild form of the disease is imparted which protects from future more virulent attacks. The disease has some resemblance to glanders in the fact that it commences, sometimes, as an external or superficial disorder, sometimes, like most other specific fevers, as an internal or constitutional complaint. In the former case an inflammatory swelling arises on some part of the surface exposed to the air, which is attended with much redness and brawniness of surface, and in the centre of which soon appears an area of gangrene, or sloughing. This affection is commonly known as malignant pustule. In some instances the disorder remains purely local, and recovery takes place with the subsidence of the local mischief. But not unfrequently death ensues, either from constitutional disturbance due to the severity of the local inflammation, or with the usual symptoms of constitutional anthrax. The internal form of the disorder is the more common, and also the more fatal. Its period of incubation is uncertain. At its commencement the patient complains of feverishness, with weakness, chills, and usually perspirations. After a short time the symptoms become almost suddenly aggravated; the temperature rises, the pulse and the respirations become rapid, difficulty of breathing with precordial anxiety comes on, the surface gets cold and livid, and the patient falls into a condition of prostration or collapse. Sometimes there are signs of local congestions of the lungs, or of the abdominal organs, and hæmorrhages are not unfrequent; and very often delirium, coma, and even convulsions occur before the fatal termination. The disease is fatal in large proportion, and death usually ensues in the course of four or five days.

Now anthrax fever has never prevailed as an epizootic in this country, and British medical practitioners and veterinary surgeons have as a rule had no experience of it, and have hence been almost certain to overlook or to misinterpret isolated cases of it. In the year 1878, however, the attention of Dr. Russell, the Medical Officer of Health for Glasgow, was called to a group of mysterious attacks of disease, attended with a high mortality, which occurred at a factory in that town, among workers in Siberian horse-hair. He ascertained that this mysterious disease was anthrax fever, and concluded that the workmen had contracted it from handling affected horse-hair. Two years later the attention of the Local Government Board was directed to the existence at Bradford of a disease frequently fatal, but only imperfectly understood; and Mr. Spear was directed to inquire into the subject. The following quotation from Dr. Buchanan's report for the year 1880 summarises the results then arrived at: "Mr. Spear found that, in sequence to a large number of occasional cases, the nature of which had at the time of their occurrence been matter of suspicion, some thirty or forty cases, definable as anthrax, had occurred in eleven months among woolsorters in Bradford and neighbouring districts, and that no less than twenty deaths had to be ascribed to this cause. The disease, whether it showed itself more by external or internal symptoms in the persons of the affected woolsorters, was found by pathological observation to be uniformly characterised by the presence of the bacillus anthracis in the blood and organs; and the material of the disease had been received, it appeared, into the body of the worker, now by the way of the skin, now through the lungs or stomach. Experiments, conducted by Dr. Greenfield, in aid of Mr. Spear's enquiry, showed that in all cases where decomposition did not interfere with the result, the fluids derived

from fatal cases of the disease were capable of producing the same disease in mice and guinea-pigs into which those fluids were inoculated. An unintentional experiment on cows and sheep was made by the irrigation of certain fields with the washings of wool from a factory near Keighley, with the result of producing unexpected deaths among the animals pasturing on the fields; their disease having characters similar to those observed in the human subject, particularly in the presence of the same bacillus anthracis in the fluids of the body."

"Not all wools and hairs were found equally capable of producing the disease. The dangerous wools were foreign wools, and the most dangerous of all was a kind of mohair coming from the Van district of Armenia. There appeared reason, moreover, for believing that the infective quality resided more especially in the 'fallen fleeces' of a woolbale; in that portion, namely, of the wool which had been shorn from dead animals, and which forms about five per cent. of the whole."

In the report of the Local Government Board for 1882, are comprised the results of a further enquiry by Mr. Spear, with respect to the occurrence of the same disease among persons engaged in the London hide and skin trades. It would take too long to consider the details of this very interesting report. But it shows conclusively that anthrax fever, in both its forms, is of not unfrequent occurrence amongst those concerned in the industries referred to; and that, as might be supposed, the chief sufferers are the persons who have to handle the raw hides coming from abroad, namely, wharf-labourers, sorter's labourers, and tanner's labourers. No evidence of the occurrence of the disease could be traced amongst fellmongers. It is an interesting fact, too, as further proof (if need were) of the nature of the disease amongst the workmen in London, and of its virulence that in consequence of the removal from a tannery, in which there had been special recent prevalence of anthrax, of refuse for manurial purposes to a farm near Guildford, a destructive outbreak of anthrax occurred among the farm horses and cattle, just as had occurred previously in connection with the Bradford epidemic. These several enquiries show conclusively that the workmen who have to do with foreign hairs and hides incur a serious risk of contracting anthrax. There can be no doubt that many such attacks have been overlooked up to the present time, and it is satisfactory to know that now at length the danger is generally appreciated, and that precautionary measures against it are generally adopted.

There are still two or three diseases which may, I think, be fairly called industrial diseases, to which, before I conclude, I should like to advert: one is the so-called "clergyman's throat," another is the affection known as "writer's cramp," or scrivener's palsy. Clergyman's throat is not limited to members of the clerical profession; but is an affection to which all habitual or professional speakers and singers are liable. It is a form of follicular pharyngitis, which is caused by the constant over-exertion of the voice, especially if that over-exertion be continued at times when the patient is suffering from catarrh, and which, if the over-exertion be continued, is apt to become chronic and incurable and to incapacitate the sufferer from his duties. Scrivener's palsy is a peculiar affection to which clerks and persons who have to do much writing are liable. It consists in a kind of momentary loss of power or spasm, which affects the muscles of the thumb and fingers engaged in writing, which in advanced cases involves the muscles of the arm as well, and which either causes the writer to drop his pen, or to make some sudden movement that checks or mars his writing. In a large number of cases the disease is progressive, and finally renders continuous writing wholly impossible. Sometimes its development in one hand has compelled the sufferer to learn to write with the other hand. Unfortunately for him, however, the affection is apt to spread from one side to the other. Scrivener's palsy is only the best known, and perhaps the commonest, of a group of spasmodic or paralytic affections to which persons who have acquired skill in the use of particular groups of muscles are liable. The pianist, the swordsman, and others whom it is needless to enumerate, suffer from analogous disorders.

The sketch of industrial diseases which I have given is short and necessarily incomplete. I cannot pretend that I have consulted all the literature on the subject which has accumulated during the last few years; and my personal studies are limited to two or three enquiries which I conducted many years ago for the Medical Officer of the Privy Council, and to the casual material which has been afforded me by my position as an officer of health and physician to a large hospital. It is probable, therefore, that there are some well-known industrial diseases with which I have no acquaintance; and, with respect to some of those which I have brought under your notice, I cannot speak with any certainty as to what their present prevalence is as compared with their prevalence years ago. Moreover, I have not ventured to enter at any length on the important question of their prevention. I console myself, however, with the consideration that it would have been utterly impossible for me, even if my knowledge of the subject had been profound, to give an adequate account of industrial diseases in the limited time placed at my disposal; and that my paper will be completed and corrected by the observations it will doubtless elicit from those whose knowledge, of at any rate particular parts of the subject, is much more intimate and much more recent than mine.

ON COWS' MILK AS A VEHICLE OF INFECTIOUS AND EPIDEMIC DISEASE.[1]

By W. N. THURSFIELD, M.D.
Medical Officer of Health to the Shropshire Combined Districts.

To fully consider the above subject would involve questions in comparative and human pathology of themselves more than sufficient to occupy the time at my disposal on the present occasion. I shall therefore endeavour to confine my remarks to generally acknowledged facts, and to suggest such remedial measures as shall be equally efficacious and advisable, whatever technical views may be held as to the extent and precise mode in which cows' milk becomes a vehicle of human disease.

The subject is one with reference to which it is specially desirable on the one hand not to create undue alarm, and on the other hand not to make light of or pass over apparent sources of disease, however improbable they may appear at first sight.

The greatest risk of danger from milk lies in the fact that the chief consumers are of an age when the body is most susceptible of taking disease, and the consumption of unboiled milk may literally be said to bring the consumer into close connection with the animal from which the milk was drawn, and, always to some extent and often most intimately, with the family and domestic arrangements of at least one household and often two.

When we consider to what extent milk is a reflection of the bodily condition of an animal and of its food,

[1] Abridged from a paper read at a Conference at the International Health Exhibition on June 12, 1884.

and how very absorbent milk is of volatile matters in the atmosphere, and how prone to undergo septic changes, the wonder is not that so many but that so few bad consequences have been hitherto traced to its use.

To Dr. Michael Taylor, of Penrith, is, I believe, due the credit of having in the year 1858 first recorded a milk epidemic in an account of an epidemic of typhoid fever. The subject appears not to have attracted much attention until Dr. Ballard's well-known report of an epidemic of typhoid fever in Islington in the year 1870, since when records of about a hundred epidemics, alleged to be traceable to milk dissemination, have been published, and others not published have been noted.

The connection of an epidemic with milk supply is a matter with regard to which the statistical method, unless applied with scientific accuracy and rigorous impartiality, may readily lead to a wrong inference, and a coincidence be recorded as a consequence, and this would doubtless apply to some of the epidemics recorded.

Making allowance for all doubtful cases, it may, I think, be accepted as an absolute fact that epidemics of typhoid fever and scarlet fever have been repeatedly disseminated by milk, and that there is very strong evidence that diphtheria has been so disseminated, and instances have been adduced by most competent observers. Other infectious diseases have been alleged to have been so transmitted, but the cases are not so numerous, nor the evidence so clear. If, however, we accept the transmission by milk of the diseases above named, we are justified by our knowledge of the nature of infectious diseases generally, in assuming that to a certain degree the same danger may exist in the case of all infectious diseases, and should be guarded against.

With a view to propose efficient preventive measures it is necessary to consider the probable mode in which milk becomes a vehicle for the germs of infectious disease. I am certainly expressing my own opinion, and I believe also the opinion of the majority of those who have carefully studied the subject, that this is a point on which we have as yet very little accurate knowledge. In the case of the majority of milk epidemics investigated, typhoid fever has been the disease involved, and in the majority of such cases, specifically contaminated water added to the milk has been regarded as the source of the evil. This doubtless has been the case in many instances, but this theory does not appear to satisfactorily explain all the epidemics of typhoid fever, nor the epidemics where scarlet fever or diphtheria has been the disease involved. Another possible explanation is that the milk may be a simple carrier of the disease in the same way that articles of clothing convey the germs of disease. This may explain some cases. There still, however, remain a considerable number of epidemics in which the above explanations do not suit the observed facts. Another explanation is that milk itself may become specifically infected and serve as a nidus for the disease germs, in other words may itself catch the disease. Certainly milk is specially calculated by its composition to act as a cultivation-fluid for germs proper to the human body, though it is difficult to believe that it would readily so act at the ordinary temperature. Freshly drawn milk is, however, warm, and in cases of bovine sickness the milk temperature is still higher, and the milk in a more favourable condition to act as a cultivation fluid for any zymotic germs it may come in contact with.

Another suggestion is that milk epidemics may be explained on the theory that the disease is the expression in the human subject of some apparently different disease in the animal. If this were the case those engaged in investigations into the origin of outbreaks of infectious disease would be expected to find a larger percentage of inexplicable cases (*i.e.* cases where the source of infection was not readily traceable) at farmhouses or cottages where cows were kept. Such is, however, certainly not the case in scarlet fever or typhoid fever. In diphtheria I will not give a positive opinion, and it has struck me that very frequently outbreaks in which the source of infection was not readily traceable, have appeared in connection with a certain class of small farms where a few cows were kept, but I believe this fact, if fact it be, to be explicable by the natural history of diphtheria, as in this disease, essentially a disease of rural districts, structural dampness of habitation is of all defects the one most favourable to the severity and persistent vitality of the infection, and to its recrudescence often at intervals of years, and the class of houses to which I allude are often imbedded in damp situations or on a water-logged subsoil, and structurally damp.

It has more recently been suggested that the infected condition of the milk may result from the animal being itself the subject from human infection, direct or remote, of the disease in a modified or altered form. We know that in mankind the parturient condition renders a mother peculiarly susceptible to take zymotic disease, and that in such cases salient symptoms of the specific zymotic disease are masked and suppressed, and it has been suggested that something of the same kind may take place in the case of the parturient cow, but that the disease is modified, and so slight as not necessarily to attract attention. This theory has received some support from experimental evidence. Dr. Klein, by inoculating a cow, recently calved, with the virus of scarlet fever, appears to have succeeded in producing a febrile ailment which proved transmissible to dogs by inoculation, and produced in them an apparently specific disease. The theory also receives some indirect support from certain exceptional features which are said to have been observed in the character of the disease in milk epidemics, and it is remarkable in what a large proportion of the epidemics of scarlet fever believed to have been disseminated by milk, there is distinct evidence of the cows having been milked by persons in close contact with cases of the disease in the human subject. The above explanation could not, however, apply to those instances in which the milk has been assumed to have become infected after it has been removed from the dairy farm.

In addition to recognised human diseases, milk may become a vehicle for the transmission of recognised bovine disease to man. That the infection of foot-and-mouth disease (*eczema epizootica*) can be so transferred there is no manner of doubt. Numerous instances have been recorded. When, indeed, we consider how sensitive the secretion of milk is to the general constitutional condition of the animal, and that the first symptom of illness noticeable in cows is a sudden and marked diminution in the yield of milk, it is difficult to believe that the milk from a diseased animal can be otherwise than injurious. We are, however, met with very contradictory evidence.

No amount of negative evidence can, however, upset positive cases, and we are justified in the conclusion that if there is considerable uncertainty, there is sufficient evidence of risk to render it necessary to take such precautions as are indicated by experience.

It is asserted by some high authorities that bovine tuberculosis is transmissible to man. That a considerable proportion of milch cows are affected with tubercular disease is admitted, but whether the disease be or be not transmissible to the human subject through the milk, is a matter difficult to prove, and a point about which there is much controversy, though considerable evidence of probability has been adduced. If such

transmission can be satisfactorily proved or even shown to be frequently probable, the question of this disease would then transcend in importance any previously referred to by me. All we can venture to suggest as practicable at present, is that no milk should be sold from cows in a recognised stage of tubercular disease.

It is, however, an acknowledged fact that cows fed in urban cowsheds are much more prone to this disease than those fed in the ordinary way in the country, and if the recent large development of the milk trade from the country has had the disadvantage of prolonging the interval during which milk is kept before being delivered to the consumer, and thus affording more time for septic action, this is more than counterbalanced by the lessened danger of the milk being derived from tuberculous animals.

There have recently been recorded outbreaks of epidemic sickness, traceable to milk which, although presenting features agreeing with no recognised human or bovine disease, have presented sufficient uniform characteristics to entitle them to be considered as belonging to a specific disease. It is uncertain whether these symptoms depend upon some epizootic disease transferred to the human subject (and it would be in accordance with analogy and experiment, that an animal disease when transferred to man, may present symptoms varying in degree and kind from those which it originally presented), or are the result of the evolution, under favourable conditions, of a special degree of virulence in septic germs received from without, and not in any way connected with the animal source of the milk ?

One notable fact in connection with milk epidemics is that they have generally occurred in connection with milk purveyors who have been under contract to supply a certain amount of milk daily to be subsequently retailed. This is possibly open to the explanation that in such cases only, as a rule, can the necessary statistical evidence be forthcoming and attract attention. It is, however, I trust no libel on human nature to say that milk purveyors so situated would have greater inducement to continue the use of milk from cows suffering from slight illness, or to bring into trade use milk from parturient animals earlier than would otherwise be done, and, assuming the animals to be the source of the mischief, the mixed milk of twenty cows would at all times be very much more dangerous than the milk of twenty cows used separately. Although in acute disease the quantity of milk is decreased, the secretion does not generally cease altogether, and it is an important part of the treatment and essential for the well-being of the animal that it should continue to be regularly milked, and some people would probably honestly believe that if this milk was mixed with a large quantity of wholesome milk, no harm could ensue.

It is a popular belief that if the provisions of the Adulteration of Food Act are actively put in force, and the duties of the public analyst efficiently performed, sufficient protection is afforded against evils traceable to milk supply. Chemical analysis, especially when applied to mixed milk from a number of cows, although indispensable to expose a marked addition of water or abstraction of cream, is valueless as an indicator of infected milk, and, as negative evidence of danger or positive evidence of infection, is as fallacious in the case of milk as it is in the case of water.

There are certain circumstances under which, when the individual members of a community cannot well protect themselves, it is recognised to be the duty of the State to furnish as far as possible the necessary safeguards. This principle as applied to milk has already been endorsed by our legislature, and acted upon in Sec. 34 of the Contagious Diseases (Animals) Act, 1878, and by the Order in Council of July, 1879, founded on the above section, and known as the dairies, cowsheds, and milk-shops order. I propose now to bring under notice the practical working of this legislation, with a view of considering what measure of protection is afforded by it to the consumer against the risk, that, with milk, the germs of disease may be introduced into households. I think the answer must be that it affords no sufficient protection, and the reason I believe to be that this important matter, instead of being placed prominently under the operation of the laws relating to the health of mankind, has been made to occupy a very secondary and subsidiary place amongst the statutes relating to diseases of animals.

To place all dairies in rural districts under the same regulations as apply to cow-sheds in large towns would be inexpedient. Already milk is too difficult to obtain by the cottage class in many rural districts, and every care should be taken not to render this more difficult. A wide distinction should be drawn between milk purveyors and ordinary cow-keepers. The milk purveyors should be alone subject to the special regulations and license. The term purveyors should be restricted to those who sell milk by retail by sending it round from house to house, or keep shops where milk is sold as a prominent article of trade, or transmit milk in bulk to a distance for subsequent sale by retail. All such purveyors should be subject to license. Regulations are of course necessary, but what is chiefly needed is efficient inspection and responsible advice under certain exceptional difficulties.

To effectually prevent milk epidemics precautions are necessary :—

(*a*) At the house of the consumer.
(*b*) At the milk-shop of the retailer.
(*c*) At the dairy farm of the wholesale purveyor.

(a) *Precautions advisable at the House of the Consumer.*

If there is one fact which more than another has been uniformly brought out in the records of milk epidemics, it is that the consumers of boiled milk have, as a rule, escaped, and the same fact has been noted in outbreaks of an American epizootic which is readily transmissible to man, known as the milk sickness. The same protective influence of boiling infected milk has been observed abroad in connection with the experimental transmission of bovine tuberculosis to other animals. To boil milk may, for practical purposes, be said to confer immunity from infection conveyed by it, though such should never be absolutely relied upon, or when milk is known to be infected. At the present day in this country, milk is the only animal product which is habitually consumed in a raw state. There is no dietetic reason why milk should not be always cooked before consumption. The objection of many on the score of taste would disappear with use, as taste is very much a matter of cultivation. But boiling milk produces certain physical alterations which interfere with its subsequent general use when cold, and cause considerable prejudice against the obvious precaution of boiling the milk in bulk when received from the retailer.

(b) *Precautions advisable in connection with the Milk Shop of the Retailer.*

Generally those adopted by urban sanitary authorities, with the addition that, on the occurrence of any infectious disease amongst the employés, the fact should immediately be notified to the proper authorities.

An urban sanitary authority should also have the power to stop the sale of milk consigned from any particular farm pending investigations, if satisfied that they have sufficient grounds for so doing, but should be liable for compensation if the step prove to have been uncalled for or unnecessary.

It should also be incumbent on a retailer of milk, when required by the sanitary authority, to furnish a list of his customers.

(c) *Precautions advisable at the Dairy Farm of the Wholesale Purveyor.*

In connection with the above subject, there is much that is theoretically desirable that is at present not practically attainable; I believe, however, that it is possible, without omitting any requirements absolutely essential to safety, to restrict the compulsory provisions to such steps as are practicable under existing conditions. The requirements as to cubical and floor space and ventilation, of the regulations generally adopted in the case of urban cow-sheds, are unnecessary in the case of dairy farms; and I fear that in the case of rural cow-houses, requirements as to washable wall surfaces and impervious flooring could not at once be complied with, and the same would apply to the requirements as to daily registering the quantity of milk given by each cow, and taking the animal's temperature, and the restrictions as to feeding incorporated in the regulations adopted in some parts of Germany.

There are certain requirements, however, which are essential and not unreasonable.

The premises on which the business of a milk purveyor is carried on should be registered.

Every registered dairy should be provided with a plentiful supply of good potable water for the use of the dairy and cows.

The dairy used for storing and refrigerating the milk, should not be subject to animal effluvia of any kind, and should be satisfactorily drained, and the dairy should not be used for general domestic purposes.

Under the following circumstances the milk should not be transmitted for sale:—

Milk presenting any marked deviation from ordinary appearances, in either colour, smell, or general condition.

Milk from an animal manifestly the subject of constitutional disease.

Milk from an animal suffering from acute disease or infectious disease of any kind.

Milk from an animal suffering from abscess, inflammation, or painful swelling, or other affection of the udder.

Milk from an animal that has not completely recovered from the febrile state incident to parturition.

On the occurrence in an animal of any symptoms of acute disease, or a large and sudden diminution in the yield of milk, the milk should be set aside.

On the occurrence in the person or family of anyone employed about the cows or the dairy, of any eruptive or infectious disease at all, or of any throat complaint affecting three or more persons, the affected individuals should be isolated, and the fact notified to the health officer.

In most of the above requirements the milk-purveyor would be a gainer, as he would always be in a position to avail himself of responsible advice. Notification of disease need not, for obvious reasons, entail publicity, but in such cases the responsibility of the necessary isolation would devolve on the Medical Officer of Health.

I believe, indeed, inspections may be so carried out that the inspector would come to be looked upon, not as an interloper only borne with so far as the law demands, but as one in a position, under certain circumstances of disease incidence, to give advice, valuable from a commercial, as well as from a sanitary point of view.

Whatever differences of opinion there may be on technical points and matters of detail, I think that all who have carefully considered the subject will have formed a decided opinion that the adoption of regulations as to the sale of milk should be incumbent on local authorities, and not permissive, as at present, and that the regulations should be applied at the producing as well as the distributing depôts.

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ROYAL FREE HOSPITAL.

CHRONIC OTORRHŒA — SUDDEN SUPERVENTION OF CEREBRAL SYMPTOMS, RAPIDLY FATAL BY THROMBOSIS OF LATERAL SINUS.

(Under the care of Dr. COCKLE.)

(Notes by Mr. Charles Lane Sansom, M.R.C.S., House Physician.)

Arthur F., aged 15, admitted to the Rhodes Ward, March 17th, 1884.

Previous History.—He has been treated in the out-patient department for otorrhœa, of some years standing; otherwise he has always enjoyed fairly good health.

Condition on Admission.—Pale and thin, but fairly well developed. Face has rather a dusky hue, and the expression is very anxious, and of marked cerebral type. Skin hot and dry; temperature 104°; pulse 130, peculiarly hard; tongue dry and cracked; urine sp. gr. 1,020, no sugar or albumen present; heart sounds normal; respirations 48 per minute, very rapid and shallow. There is a thin purulent discharge escaping from the right ear; no swelling or tenderness over the mastoid process. Complains of headache, with, he says, the feeling of a tight band round his head. Ophthalmoscopic examination showed the retinal vessels of the right eye congested. No tenderness of the scalp present.

Condition Four Hours after Admission.—Sudden increase of headache, which is now very intense; he screams out if any part of the body is touched or moved; prefers lying on the right side. His face is contorted by general spasmodic twitchings, and his look is peculiarly fixed and staring, with slight and variable internal strabismus of the left eye; sudden contraction and dilatation of the pupils at irregular intervals, marked intolerance of light preventing all further ophthalmoscopic observations. Seems to understand a question, but a short interval elapses before an answer is given. Food is refused, but he complains of great thirst. There is no difficulty in swallowing. This condition lasted nearly an hour, when a remission of all the symptoms took place, and a short rest was obtained.

March 18.—Temperature, which had sunk to 101° during the night, is now 104°; pulse 146, still hard; respirations 48, very shallow. Was restless, and delirious at times, especially after several attacks of headache, similar to that described above, but has slept at intervals during the night. The headache is now more severe, several exacerbations occurring during the day. Twitchings of the face more marked, especially of the corrugatores superciliorum. The fixed look of the eyes and strabismus still present, the condition of the pupils remains the same; photophobia increased. The peculiar hydrocephalic cry is very marked. He screams out if touched or moved, and complains that "someone is tying his head up too tight;" seems to try to remove something from the forehead. The mental faculties remain the same. Tache cerèbrale and ankle clonus well developed, but no exaggeration of the other reflexes exists. Small petechiæ have appeared all over the body, except the face and neck.

Ordered Hydr. c̄ cretâ gr. ii, twice a day, three leeches to be placed behind the right ear, and ice to the head.

March 19.—Has had scarcely any sleep during the night, attacks of intense headache occurring very frequently, and the delirium following being more violent. He now appears perfectly indifferent to surrounding objects, but swallows a little nourishment when put into his mouth. The occasional screams are now changed into a low continuous moan. The twitching of the face and strabismus remain the same as yesterday. Temperature 103°; respiration 56; pulse 190 (as nearly as could be counted), is now scarcely perceptible. The muscles of the limbs are flaccid, but those of the abdomen are rigid. He no longer understands what is said to him. The evacuations are passed into the bed. When called to see him half an hour later, coma rapidly supervened, and he died whilst in this condition ten minutes later. At no period of the case did vomiting occur.

Necropsy Twenty-six Hours after Death. (Made by Dr. Harrison Sainsbury.)—Numerous small petechiæ on the surface of the body, but no other discolorations.

Thorax.—A few scattered and recent adhesions between both pleuræ; there is also six ounces of discoloured semi-purulent fluid in the left cavity. Scattered over the lungs numerous small infarctions, varying in size from a pea to a walnut, are seen; in the bounding walls are small patches of gangrene. Heart and pericardium healthy. Nothing of pathological importance found in the abdomen.

Skull.—The pia mater and the arachnoid are healthy. There is some discolouration present on that part of the right lobe of the cerebellum which corresponds to the lateral sinus, the brain substance here being softened and pulpy, but normal elsewhere. There is no excess of fluid in the ventricles. The brain being removed, the dura mater is found softened, and a greenish discolouration is seen over that portion which invests the right temporal bone. On stripping this off from the bone, a discoloured clot is found, adherent to and occupying the lateral sinus, and extending some way into the jugular vein; the sinus is softened. The greater part of the surface of the temporal bone is smooth and firm, but at one spot in the groove for the lateral sinus it is discoloured, soft, and readily breaks down, disclosing a carious cavity, barely a trace of the structures of the middle ear remaining.

Remarks (by Dr. Cockle).—This case possesses interest, not only as illustrative of the admitted difficulty—indeed, at times utter impossibility—of arriving at a precise diagnosis of thrombosis of a lateral sinus, but also from the nature and extent of the chest lesions. I was disposed to regard the case as one of inflammation of the meninges from extension of the disease in the temporal bone, with possible abscess of either cerebrum or cerebellum, imminent or actual. Death followed too soon to allow the symptoms of pyæmia full development. But there seems reason to believe that, had no thrombosis occurred, abscess of the cerebellum would speedily have followed.

The New Febrifuge Kairin.—The reports of the remarkable anti-pyretic effects of kairin continue to increase. Most observers seem to agree that it is best to begin in adults with a dose of about 12½ grains, to repeat this two hours later, then to administer 9 grains every two or three hours, until the desired effect—decrease of temperature—has been obtained, when a smaller dose, about 5 grains, employed every three hours, usually suffices to keep down the temperature. But at the least indication of this falling below normal the remedy must either be omitted or given in very small doses and at very long intervals—say 3 grains every twelve hours. Should, however, the temperature again ascend, the same course as described must be gone through anew.—*Philadelphia Medical Reporter*, May 24.

Medical Times and Gazette.

SATURDAY, JUNE 21, 1884.

We have no doubt that cases of over-pressure of work in schools have occurred and will now and then occur in spite of all regulations to prevent them; but we believe that their extent and frequency have been much exaggerated; and it is certainly very remarkable how little care and judgment is as a rule shown in the selection of the alleged cases brought before the Houses of Parliament. A typical example of this was the subject of a question put in the House of Commons on Thursday week. Lord A. Percy asked Mr. Mundella whether he could state the result of his inquiries into the case of a boy named Wyles, brought before the Shoreditch Board of Guardians in March last, when two medical men had reported him insane, and his mother had said his insanity was due to overwork at school; and had further stated he had complained of having been beaten on the head with a ruler by a pupil teacher. Mr. Mundella replied that the London School Board had appointed a Committee to enquire into the case, and their report was to the following effect: The boy was ailing when he went home from school to dinner on a Wednesday; his mother kept him from school, and gave him some domestic medicine; next morning he had convulsions, and a medical man was sent for. The following morning—the Friday—it was found the patient had scarlet fever; and the case progressed favourably for a time, though it is not clear whether he was continuously under medical care. However that may have been, in the following week the boy was allowed by his mother to get up; and on the Monday week after the appearance of the rash he was out in the garden. He caught cold, and the next day had dropsy. All the evils liable to follow on such a state of things occurred, and, according to the report of the Committee, "cumulated into insanity." Mr. Mundella does not seem to have given any information as to the duration or the character of the insanity; but when the Committee reported on the case the boy was so far better as to be at home again. The Committee found that the boy had been beaten at the school, but there was not any evidence that he had been struck on the head; and Mr. Mundella added that the pupil teacher who, in disobedience to the rules of the Board, had inflicted corporal punishment, had been dismissed the service. It is clear enough in this case that the illness was entirely due to an attack of scarlet fever, and to the want of proper care of the boy by his mother.

It is well-known that Dr. Crichton Browne has taken great interest in this question, and that he has written a report on the subject; and it appears that some members of each of the two Houses of Parliament are much exercised in their minds because this report has not been published. On Friday last, Lord De la Warr asked the Lord President of the Council if he did not consider that Dr. Crichton Browne's re-

port ought to be laid on the table, as it referred to a subject which had lately been much under public notice, and would probably ere long be again before the House. Lord Carlingford, however, did not agree with the noble earl as to the character of the document in question. It was not, he declared, a report to the Education Department, but a letter of enormous length addressed to the Vice-President of the Council. It had originated in a conversation between that gentleman and the writer; and the former had been much astonished at receiving a document of such portentous length. The Education Department were in no sense responsible for it, and were not going to make themselves responsible for issuing it as a Parliamentary Paper. Lord Carlingford very naturally, both as a minister and as a ratepayer, thought it would be extremely inconvenient if anybody had the power to discharge such a document at the head of any public department, and then to require that department to publish it in the form of a Blue Book. He was good enough, however, to add that Dr. Crichton Browne was at liberty to publish the document himself.

In the House of Commons on the same evening Mr. Mundella was pressed to place the letter in question in the hands of the Members before the Education Estimates were brought forward; but in vain. The Vice-President of the Council said it had nothing whatever to do with the estimates, and was not in any respect an official document. He was, however, more polite to Dr. Browne, and more communicative to the public than his chief had been; for he informed us that the paper which has excited so much interest is a voluminous essay on a great number of disputable questions, relating not only to education, but also to medicine, lunacy, ethics, and social and vital statistics; and out of respect for Dr. Browne a *résumé* of it will be added to some general reports, from inspectors and others, which are shortly to be laid before the House. He added, however, that all those general reports are in contradiction of Dr. Crichton Browne's conclusions.

It cannot be denied that, as a rule, whatever Dr. Crichton Browne writes is not only very readable but well worth reading; and it will be generally admitted that, as a rule, a *résumé* of a document is but a very imperfect, pale, and uninteresting shadow of the document it is intended to represent. But on the other hand, the Parliamentary printers' bill every year, notwithstanding constant efforts of reformers to keep it down, is so enormously heavy that our high officials may easily think themselves justified if now and then they refuse to print a paper at the national expense, especially if they have no particular wish that the public should have the advantage of seeing it. Consequently, on their own showing, Lord Carlingford and Mr. Mundella have in this matter acted as brave and virtuous guardians of the public purse, and Dr. Crichton Browne has no right to feel aggrieved if they do seem to imply that, taking advantage of the innocence and inexperience of the Education Department, he has hoped to make them publish for him a voluminous essay *de omnibus rebus, et quibusdam aliis*. But Dr. Browne's explanation of the history of his report gives, as was to be expected, quite another view of the matter.

Dr. Crichton Browne, in his letter to the Editor of the *Times*, published on the 16th instant, confirms Lord Carlingford's statement, that his (Dr. Browne's) letter originated in a conversation with Mr. Mundella; but it appears that that conversation took place at an interview spontaneously and specially requested by Mr. Mundella; the result of which was that Mr. Mundella requested him to visit a number of elementary schools, accompanied by an inspector of his department, and to report to him any observations he might have to make as to the effects of the present system of education on the health of the children. Dr. Crichton Browne was very reluctant to undertake a work which he felt would be a very onerous one; but yielded at last to Mr. Mundella's persuasion, only bargaining that he should be at liberty sometimes to visit schools unaccompanied by an inspector. This he was authorised to do; and then he promised to do his best to carry out Mr. Mundella's wishes, and to incorporate in his report comments on some vital statistics, about which it seemed to him that Mr. Mundella had been seriously misinformed. Further, on the 19th of February last, Mr. Mundella stated in the House of Commons that "he had invited Dr. Browne to visit some of the public elementary schools in London, in company with one of Her Majesty's Inspectors, and to favour him with his opinion of their work from a sanitary point of view." It may surely be fairly said that when Lord Carlingford stated that Dr. Browne's letter or report "in no proper sense originated with the Education Department," and Mr. Mundella declared that it was "in no respect an official document," they made statements that, to use a favourite phrase of their political chief's, are perfectly inaccurate. At Mr. Mundella's earnest request, Dr. Crichton Browne, at great inconvenience to himself, has performed what Mr. Mundella said would be an excellent public service; and his reward is that the Government Department for the information of which he, by special request, laboured, tries to disown all responsibility for his report, and disparages it as being voluminous, highly controversial, abstruse, and so on. Such conduct cannot but excite the suspicion, to say the least, that the report really contains, as its author believes, "strong evidence that over-pressure exists in elementary schools, that it is even now injuriously affecting the health of the children, and that it promises a rich harvest of degeneration hereafter;" and that is not a report of the character that the Vice-President of the Council hoped to obtain.

During the discussions on the Educational Estimates in the House of Commons on Monday evening, several members commented unfavourably upon the manner in which Dr. Crichton Browne has been treated by the Educational Department; and Mr. Mundella finally said, that though he did not himself choose to incur the responsibility of publishing Dr. Browne's report, yet, if any honourable member or members thought fit to move for it, it should be printed at once. As Mr. Mundella was driven to make this concession,

he could hardly be expected perhaps to do so graciously; but a minister of his force and position should not be undignified and petulant even when complying against his will.

A CASE connected with the subject of over-pressure in elementary schools was decided by the Queen's Bench Division of the High Court of Justice, on the 16th inst., at the instance of the Bradford Borough Magistrates. The mother of a boy attending the Bradford Board School gave notice to the master that she had forbidden her boy to do any more home-lessons, and asked the master not to set him any more. The master continued, however, to set home-lessons, and when the boy came to school one morning having, in obedience to his mother, prepared no lesson, he was kept in after school hours till he had learned the lesson in question. The mother summoned the master for an assault, but the magistrates found there had been no actual assault, and dismissed the summons; stating a case for a higher court. Mr. Justice Matthew decided that the master had no authority to impose upon the children the duty of studying at home. The Education Acts being a statutory interference with the liberty of the subject, must as such be construed strictly; and neither the acts nor the bye-laws made under them gave authority for enforcing the preparation of lessons at home. The child had therefore in this instance been illegally punished—by being kept in beyond school hours to do what the schoolmaster had no power to order him to do; and the detention amounted in law to an assault.

A QUESTION put the other night in the House of Commons by Mr. Healy, M.P., to the Chief Secretary to the Lord Lieutenant of Ireland, relative to the recent appointment of Dr. Stewart Woodhouse as an Inspector of the Irish Local Government Board, met with the fate it deserved. Mr. Healy asked whether Dr. Woodhouse has had any experience as a dispensary or union medical officer, or as a medical officer of health; and, if not, how he became entitled (other than by acting for a short time as temporary inspector) to be placed over the numerous efficient Poor Law Medical Officers of Ireland who have acquired a practical knowledge of the duties of such a position by passing through these different grades of the service. Also whether Dr. Woodhouse is a member of the secret society of Freemasons, and how many members of the Local Government Board, and of their Inspectors, are members of that society. The Chief Secretary replied that neither he nor the Vice-President of the Local Government Board knew whether Dr. Woodhouse was or was not a Freemason, and that no enquiry on the point would be made. He added that the appointment was made in consequence of Dr. Woodhouse's high professional qualifications and valuable services. Dr. Woodhouse is an Ex-scholar and Diplomate in State Medicine of Trinity College, Dublin. He rendered signal public service in investigating, on behalf of the Local Government Board, the outbreak of fever in Mayo so long ago as 1879, and more recently in reporting to the Government on the distress in Donegal in 1882. For some months back he has, for the third time, been acting as an Inspector of the Local Government Board in connection with the "Labourers' (Ireland) Act" of last Session.

THE series of conferences held at the Health Exhibition under the auspices of the Society of Medical Officers of Health, the Sanitary Institute and the Parkes Museum were continued through last week, without any falling off of interest or success. We have selected for publication in another column two of the best papers and the two discussions which most nearly concern the medical reader. The subject of Thursday's conference was the spread of infectious diseases. Dr. Thursfield confined his attention to their spread by means of milk, while Professor Corfield gave an admirably lucid exposition of the more general aspects of the question. The subsequent discussion was chiefly remarkable for outspoken condemnation of other people's conduct. Professor de Chaumont criticised the sanitary department of the Indian Government for its obstructive attitude towards scientific investigation. Mr. Fleming blamed the inspectors of slaughter-houses, which were a disgrace to civilization, and Dr. Priestley animadverted on the carelessness of heads of families in respect to infectious disease occurring in their families. The chairman, Dr. Alfred Carpenter, concluded the conference by suggesting certain possibilities as to the evolution of hybrid germs.

FRIDAY'S conference dealt with a somewhat inflammatory subject—the notification of infectious diseases, and there was a considerable determination of doctors to the conference-room. The chairman, Lord Fortescue, who described himself as an old sanitary reformer, opened the conference in a most broad and statesmanlike speech, in which he pointed out the dangers of interference with the liberty of the subject, and the inadvisability of multiplied official interference. Dr. Alfred Hill and Dr. Alfred Carpenter then read the papers which we have given in abstract elsewhere. The former advocated imperative notification, and gave preference to the dual system—notification both by doctor and householder. The latter placed his trust more in moral suasion, which he would leave in the hands of the licensing corporations or the medical council. In the discussion which followed, Dr. Armstrong, of Newcastle, Dr. Dudfield, Prof. Corfield, Dr. Charles West, and Dr. Taafe, of Brighton, supported notification, while Mr. Wynter Blyth, Dr. Carter, of Liverpool, Dr. Mahomed, and Mr. Nelson Hardy expressed themselves as sceptical of the benefits derivable from the system. In spite of this even difference of opinion, the chairman, in summing up the debate, confessed that the scruples which he had expressed at starting had been dispelled, and that he thought a case had been made out for compulsory notification—not however by the doctor, but by the householder.

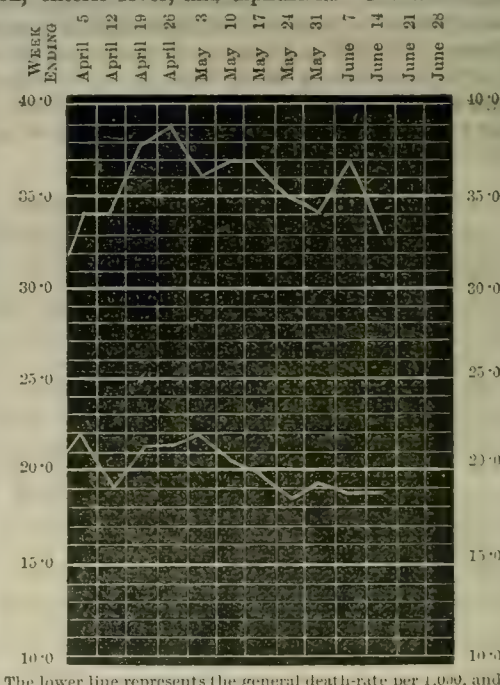
ON Saturday Mr. Wynter Blyth opened a conference on the Disposal of the Dead, with a most able and brilliant paper, which has deservedly been so fully reported in the daily papers that we need say no more of it here than that it advocated burial by rotation, the

land used for burial being surrendered after five years to agriculture or forestry. This suggestion, a little too bold and novel for the audience, did not meet with much consideration at their hands, and after a paper by Mr. Eassie, in praise of cremation, the discussion was entirely taken up by that burning question. Almost all the speakers expressed themselves as favourable to cremation, though one gentleman warned the conference that millions outside of it looked with horror on such a radical change in the disposal of the dead. The whole discussion showed, however, that there is no subject which is so rapidly ripening for settlement as that of burial by burning, as an Irishman would describe it.

The most important event of the week, however, in connection with the Health Exhibition came off on Tuesday, when the Prince of Wales formally inaugurated the work of the juries, and Sir James Paget, as Vice-Chairman of the Executive Council, delivered one of his well-devised and admirably executed harangues. He chose for his subject the relation of health to work. His description of the pattern healthy man as "one who lives long and vigorously, who in every part of his life, wherever and whatever it may be, does the largest amount of the best work that he can, and when he dies leaves healthy offspring," might form the text for a hundred sermons much needed in the neighbourhood of the Exhibition. We should find it difficult to say which was the most valuable part of the address, that in which he brought up his platoons of statistics to prove the pecuniary loss which the country sustains from illness and premature death, or that in which he placed before his audience "perfect national health" as an ideal as much worth striving for as renown for bravery, or for beauty, or for success in athletics and field sports. It would be useless to try to give in a few words the gist of Sir James Paget's address. It is all gist—a completely organised whole, from which it is impossible to extract a sentence without ruining its meaning.

There was during last week a fresh wave in the advance of small-pox, and 332 new cases were admitted into hospital, making a total under treatment of 1,238. That with such a large number of known cases, and with probably more than half as many hidden in private houses, the deaths should have only amounted to 27, ought to speak with convincing force to the anti-vaccinationists as to the effect of vaccination in modifying a disease which once had such a fearful mortality. The Metropolitan Asylums Board appear to be straining every nerve to cope with the growing epidemic; and they have opened a fresh hospital at Plaistow, in addition to the hospitals, camp, and ship already in use, and the old twin-ship *Castalia* has been moored in the river ready for further increase in the number of cases. Meanwhile complaints are being made that the central authority—the Local Government Board—gives no precise directions as to what its subordinates should do, but carefully leaves them to their own responsibility. The Board, it appears, has not yet made up its mind whether small-pox is aërially disseminable or not. In limiting the number of cases to be treated at Homerton it accepts the theory, and yet by allowing all the worst cases to remain there, it infinitely increases the risk of dissemination. At the same time it allows cases by hundreds to be fixed in the middle of one of the most crowded water-ways—the Thames—where, when there is little wind, the air swinging up and down the river with the tide, and polluted, according to Dr. Power's theory, with infective matter, can bathe the vessels of every country and impartially distribute small-pox to the uttermost ends of the earth. If small-pox has not a range of more than a few yards, why send all but the worst cases out of London; if it has, why set your centre of infection in the middle of King Neptune's highway?

Though the death-rate in London last week was only 18·8 per 1,000, the total number of deaths was as many as 25 above the ten years' average. The zymotic and respiratory deaths were both in excess of the usual number, the former to the extent of 30, and the latter to the extent of 10. The mortality from measles and whooping-cough showed a decline, but in both cases was above the average. The same was true of small-pox, enteric fever, and diphtheria. The deaths from



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the first eleven weeks of the present quarter.

diarrhœa and dysentery, on the other hand, were only three fifths of the average number, a result probably due to the low temperature on the three first days of the week. The general death-rate of the 28 great English towns was 19·8, and their zymotic death-rate 3·0, the zymotic death-rate for London being 3·3. In Scotland, the general death-rate of the large towns was 22·7, and their zymotic rate 3·6.

The recent action of the Hampstead Vestry in issuing a circular of instruction with regard to the disposal of

infectious patients, is one which might with advantage be imitated by other metropolitan vestries. Most householders, and even many medical practitioners, are still in doubt as to what course to pursue when a case of serious infection occurs in a house. In these cases it is so important to take a stitch in time, that every doctor ought to have the appropriate procedure at his fingers' ends. It is this—when a case of small-pox occurs, which it is decided not to treat in the house, but for the treatment of which in hospital payment will be willingly made, telegraph at once to the resident superintendent of the Small-pox Hospital, Highgate, stating age and sex of patient, and enquiring whether he or she can be admitted. If an answer is received in the affirmative, apply at once to the vestry officers for an ambulance. The total charge for treatment at the Highgate Hospital is five guineas. In the case of fever or diphtheria, arising under like circumstances, telegraph to the Fever Hospital, Liverpool Road. If the patient can be admitted, an ambulance will be sent from the hospital. Fee, including ambulance, three-and-a-half guineas. The Hampstead Vestry, and indeed most of the London vestries, will, on application undertake the disinfection of clothing, &c., for a small, fee. These are facts which will be sought for in "Whittaker" in vain.

An epidemic of small-pox, writes our Liverpool correspondent, began here in October with 4 cases. In November 14 cases occurred, in December 54, in January 74, in February 59, in March 60, in April 63, in May 154, and up to June 16th 103 cases. Only 51 deaths have as yet occurred. Most of the cases are being treated by the parochial authorities at Mill Road Workhouse Hospital, which now contains 206 patients and has 140 vacant beds ready for fresh cases. This hospital receives small-pox from all the parishes, the other parishes receiving the paupers who are ordinarily treated in the hospital now devoted to small-pox. Considerable objection is raised to Mill Road as a small-pox hospital. It is situated in the midst of small houses that come up close to the hospital walls, and within a quarter of a mile radius of the hospital nearly as many cases have occurred as over the whole of the city. This is ascribed to the diffusion of the poison through the air from the hospital wards. The municipal authorities are considering the question of providing a permanent small-pox hospital for non-pauper cases, but up to the present time they are in a deadlock as to the form it ought to assume. Dr. Hamilton is strongly in favour of a hospital ship and advocates his plan zealously both in his place in the Council and in the columns of the public papers. His scheme does not seem to meet with much support as yet. Most people are in favour of some kind of hospital well isolated from the surrounding houses, but where it is likely to be located, when it will be built, and whether it will be a substantial permanent structure or temporary tents, are problems for the future to solve.

The presentation of the testimonial to Dr. Joseph Rogers will take place on Tuesday, June 24th, 3 p.m., at the rooms of the Medical Society of London, Chandos Street, Cavendish Square. Mr. John A. Shaw Stewart has kindly consented to preside on the occasion.

The Queen's College Inquiry Commission opened its enquiry at Galway on the 12th instant. Dr. Moffett, President of the Galway College, said that students came from all the provinces in Ireland, but the number had been seriously diminished by the dissolution of the Queen's University and by the recent social disturbances. The medical professors gave evidence to the effect that there were a fair number of typical cases in the medical department, but that there was absolutely no opportunity for the study of midwifery, and only an occasional opportunity for studying diseases of women and children. *Post-mortem* examinations were very rare. For operative surgery and morbid anatomy the students generally went to Dublin.

A case of considerable importance to Irish Poor Law Medical Officers came before Mr. Justice Lawson and a city of Dublin common jury, on Saturday, June 14th. Although appearing ostensibly as the case of "Rogers *against* the Guardians of Youghal Poor Law Union," the action was really brought at the instance of the Irish Medical Association, for the purpose of establishing the right of the Medical Officers of Dispensary Districts—who are *ipso facto* Medical Officers of Health for their districts under the 11th section of the "Public Health (Ireland) Act, 1878"—to be paid for their services in inspecting labourers' dwellings, under the "Labourers' (Ireland) Act, 1883," with a view of ascertaining whether such dwellings are fit for human habitation. The amount claimed by the plaintiff was 28*l*. Counsel for the plaintiff contended that the services rendered were in no wise any part of the duties of a Medical Officer of Health, as set forth in the Public Health Act, or in the regulations issued by the Local Government Board for Ireland under the authority of that Act. Proof having been given of the services rendered, Mr. Justice Lawson directed a verdict for the plaintiff for the amount claimed, with leave to the defendants to move within a week to have the verdict changed to one in their favour on the ground, as argued on their behalf, that the duties in question were within the ordinary functions of a Medical Officer of Health, and were therefore not to be remunerated by special fees. It is well to remind our readers that the salaries paid to the District Medical Officers of Health are absurdly small, ranging from 5*l*. to about 30*l*. a year. In the present instance, also, we understand that Dr. Rogers' car-hire alone amounted to some 8*l*., so great were the distances he had to travel in his inspection.

"The Faculty of Medicine of Paris," writes our Paris correspondent, "has sustained a heavy loss, in consequence of the unexpected death of Professor Wurtz, and the long foreseen retreat of Professor Gosselin. Professor Wurtz, who died almost suddenly from uræmia, in the midst of a most active and busy life, has left behind him an inheritance to be divided among many competitors, like that of Alexander the Great. He was a Professor at the Faculty of Medicine and the

Faculty of Sciences, a Member of the Academy of Medicine, and of the Academy of Sciences; a Senator for life, a Grand Officer of the Legion of Honour, and a Member of the Council of the Order, President of the Board of Health (Comité Consultatif d'Hygiène), and held besides a great many minor appointments. The political successor of M. Wurtz will probably be Admiral Peyrou. The Presidency of the Board of Health has devolved upon Professor Brouardel. As to the vacant Chair of Chemistry in the Faculty of Medicine, it will be disputed between M.M. Gauthier and Grimaux, both of them eminent chemists and well deserving men. But whoever may fill the vacant Chair, no one will for a long time possess the authority of Wurtz, who had become the undisputed leader of the French School of Chemistry (Dumas having retired from active life), and who was looked up to, not with feelings of admiration, but with feelings of adoration by his pupils. A great presence has undoubtedly passed away from amongst us, and it will take a long time to fill up the gap."

"Professor Gosselin, whose health had been failing for a long time, has resigned the Chair of Clinical Surgery, and according to the system of permutations adopted in Paris, his seat has been filled by Professor Lefort, who quits the Chair of Operative Surgery. A hot struggle is taking place for this Chair between Dr. Tillany, author of a well-known book on "Topographical Anatomy," and Dr. Lannelongue, best known to English readers as the surgeon who attended Gambetta in his late fatal illness. The Faculty was quite recently on the point of losing one of its most valuable members through an unexpected accident. While superintending certain repairs on his immense estate at Carqueiraune (Var) Professor Richet narrowly escaped being killed by the sudden falling of a wall on which he was actually standing at the moment of the accident. By a most unfortunate coincidence, Madame Richet, who had just come up, was crushed by a huge stone, which killed her on the spot. A stonemason was buried under the wall, and other persons were more or less severely injured. The eminent professor has met with universal sympathy under this most severe infliction. The funeral of Madame Richet, which took place at Paris, was attended by a dense crowd, which comprised nearly all the political, scientific and literary notabilities of the French capital."

"A most animated discussion took place in the Academy of Medicine, with respect to a paper read by Dr. Luys, on the Physical Movement of the Brain. While most communications presented to that learned body are discussed in a spirit of high impartiality and perfect good breeding, the "*mobilité*" of the brain gave rise to an unexpected exhibition of temper between the venerable Professor Sappey and Dr. Sée. An old feeling of personal enmity, which had been lying hidden for several years, suddenly broke out into a flame. The discussion, after lasting several days, was at length brought to a close, after an elaborate reply of Dr. Luys, in which he endeavoured to refute the principal arguments of his opponents. The general tendency of the discussion was opposed to the views of the eminent neurologist, it being generally allowed that while there exist physiological movements of the brain, such as those produced by circulation, collapse during sleep, and other causes, there are no physical displacements of the cerebral mass within the cranial cavity; so that a man may bend forwards without knocking his brain against the *os frontis*, and may roll from side to side during a restless night without altering the respective position of the skull and its contents. Dr. Luys intends to bring forward new experiments in support of his views. It is admitted on all sides that these displacements of the brain, if they actually exist, are comprised within extremely narrow limits, and never exceed a few *millimetres*."

"Several important Bills concerning medical subjects are at the present moment lying before the French Legislative Assemblies. One of these regulates the future condition of medical practice in France; another is concerned with the vast and important subject of lunacy, the whole fabric of the celebrated law of 1838 having become more or less obsolete, and requiring a total revision. When the reports upon these subjects are laid before the Senate and Chamber of Deputies, I will send you full information upon these highly interesting topics."

The Berlin Statistical Bureau is stated to be actively engaged in the preparation of a statistical account of all the hospital establishments of the German Empire, with especial reference to their sanitary provisions. With this aim, a comprehensive circular of questions has been distributed among all the clinical establishments, and civil and military hospitals. Material which has already been received in abundance, is now undergoing inspection and editing.

The Medical Officers of Schools' Association has lost but little time in giving evidence of its capacity for useful work. Towards the end of last week the Council issued a list of questions with the object of ascertaining the means adopted in different schools when dealing with the various aspects of infectious disease. We understand that the original draft of these questions was submitted to the consideration of the medical attendants of the principal educational establishments of the country, so that in their present form, and as regards the special branch of the subject with which they deal, they may be taken to touch on most, if not on all, of the principal points which are considered to deserve consideration, or to require further elucidation by those who are frequently brought into contact with one of the most important and interesting problems of school hygiene. The queries are about twenty in number, but they are so arranged that many of them can be at once and fully answered by the insertion of a simple "yes" or "no," or by a few figures, in the blank space which is appropriated to each of the replies. It being clearly impossible to adequately cover a large extent of ground in this manner at one time, the enquiries have, on this occasion, been limited to but one section of the subject.

The kind of information sought is definitely stated in each case, so that it may be easily rendered and in few words, while sufficient latitude is allowed for all varieties of individual and local practice; in other words, the net is cast over a limited space, but its area is clearly defined, and its mesh is so small as to catch all particles of value which come within its sweep.

Thus, three infectious diseases are specified—viz., scarlatina, measles, and German measles; and questions are put anent prophylaxis, quarantine, isolation, disinfection, management of convalescence, and the closure of the school, according as a pupil falls ill with one of those diseases during the holidays, or is exposed to their infection during the same period, or in the event of an outbreak of either malady occurring during term-time. Questions are also asked with regard to the admission of new pupils, and the return of old pupils after the holidays, as to whether certificates respecting their recent non-exposure to infection are, or are not, required from the parents or guardians. This is a good foundation, and if the paper (which is issued to schools of all classes) evokes anything like the replies which it should call forth, and if similar enquiries in the future meet with an equally ready response, the Council will be put in possession of material which should enable them to go far towards fulfilling the declared object of their labours, viz., "to collect and formulate the methods adopted by the various schools of this country, for dealing with the different aspects of infectious disease."

It is scarcely to be expected that the replies to such questions will exhibit a marked uniformity on all points; indeed, it is the admitted differences of opinion and of treatment—the somewhat chaotic variety of the usages at present in vogue—which, together with the acknowledged importance of the subject, prompted this particular line of investigation. It is hoped that the information asked for will be not only fully, but promptly rendered, so that there may be time for some sifting and classification of the replies prior to the 24th of next month, when a paper dealing with this subject will be read by Dr. Andrew at a meeting of the Association, and when the discussion to which it is hoped this paper will give rise will afford an opportunity for explaining the reasons which are held either to justify or to condemn the various methods adopted under apparently similar conditions. A further opportunity for discussing the subject will be afforded at one of the series of International Conferences on "School Hygiene," which will be held at the Health Exhibition on August 1st.

The elaboration, adoption, and publication of a set of rules for dealing with infectious disorders in their relation to school management, formulated after careful consideration and ample discussion, embodying the experience of those whose lives are spent in dealing with the question in all the aspects of both its social and medical relations, and revised by those who are specially engaged with the broad subject of national hygiene, is a work well worthy of the labour which it must involve, and of the support which it should secure from professional men and laymen alike. It could not but result in the better care of the young, and in strengthening the hands of all school authorities with something more weighty and conclusive than the opinion of an isolated medical attendant, however capable, or even the *ipse dixit* of the head-master, can ever be. We are, therefore, not astonished to learn that the governors of more than one important school have, unasked, already decided to contribute towards the funds of an Association whose work, if carried on as such a beginning promises, will redound so largely to the benefit of education. Mind and body are so inter-linked in the present race for knowledge, and with the due training of both the intricate details of school hygiene are so closely woven, that there appears some near prospect of the medical officer of a school becoming practically its head-master. Everyone, then, should feel the necessity of affording him all possible aid in fulfilling a trust which it is certainly not his interest to abuse.

A report of some judicial proceedings of a painful character has reached us from New Zealand. An inquest was held at Kaitangata, in that Colony, upon a patient who died from rupture of the uterus and vagina during labour. She was attended by a Dr. Parry, who, it was insinuated, was the worse for drink. Dr. Robert Stuart Reid, and Dr. Low, gave evidence to the effect that such laceration must have been produced by external violence, and should not have occurred if proper care had been taken. Guided by this evidence, the jury came to a verdict that "death resulted from hæmorrhage caused by a lacerated wound in the vagina and back part of the womb, caused by gross negligence and improper medical treatment at the hands of Lloyd Davenport Parry." Dr. Parry was subsequently tried for manslaughter and sentenced to four months' imprisonment. A meeting of the Medical Association was held to consider the case, and the feeling expressed was very decidedly one of sympathy with Dr. Parry, who was considered to have been unjustly condemned. Judging the case from the information before us, viz., the newspaper reports, it seems to us very difficult to understand now Dr. Reid can have been justified in giving the evidence he did. The nurse stated that Dr. Parry informed those present, after his first examination of the patient, that a rupture had taken place, and it was not alleged that he used any instrument. It is well known that rupture of the uterus and vagina frequently occurs without any obstetrical interference; indeed, some authors have estimated that it occurs more often without than with. In the face of these facts it is evident that there must have been something very exceptional about the case to justify Dr. Reid in asserting that the laceration must have been produced by external violence; and we do not find any mention of the reasons for his taking this view.

The new "Marine Biological Association" have elected a very strong and thoroughly representative council and will shortly publish a first list of donations.

Fifteen hundred pounds have been already promised, and when an appeal is seriously made there is good reason to hope that the 10,000*l.* required for building and equipping the first laboratory will be speedily collected. The Association is one which may be cordially recommended to the medical profession in this country. Certain methods of biological enquiry being forbidden, it becomes all the more necessary that those which still remain should be strenuously worked, before the hearts of the anti-vivisectionists take the octopus and the medusa within their large embrace. Dr. Dohrn is already devoting some of his tables to the study of physiological problems, and it is to be hoped that the English association will follow his example.

Just now the lot of a Councillor of one of our Royal Colleges is decidedly not a happy one, and the lot of a President is still less enviable. At the best of times the head that wears a crown has, we are told, an uneasy pillow, and it does not lie the more comfortably when subjects are unruly. As *Mr. Punch*, however, has recently reminded us, crowns are quite as unpleasant things to sit upon as to wear, and Dr. Andrew and Mr. Paul Swain, who have recently been induced to attempt this operation, deserve our respectful sympathy no less than Sir William Jenner and Mr. Marshall. They have all taken upon themselves, in what they believe to be the interests of the profession, difficult and thankless duties, and all must expect to hear things said of them which, be it in praise or in blame, cannot be quite to their liking. Whether it be pleasanter to be complimented and patted on the back, or to be censured and snubbed by our leading, or rather misleading journal, it would be difficult to decide; but at any rate, every one who takes a prominent part in medical affairs must be content to put up with one or the other. Unfortunately he cannot never quite foretell with certainty which it will be.

On Monday next Mr. W. H. Smith will ask the Prime Minister if, having regard to the great importance of the Medical Act Amendment Bill, as it may affect medical education in this country, he will name an early day for proceeding with the second reading.

For a Rural Sanitary Authority it cannot be said that the records of Chester-le-Street are all that could be desired. The last annual report of the Medical Officer of Health, Dr. Cameron Morris, records a death-rate of 23, and a zymotic death-rate of 4·04 per 1,000 of population, the latter being exactly double the rate of the previous year. Again, the mortality of infants and children under five years of age was nearly half the total number of deaths registered at all ages; but, the report points out as specially worthy of notice, that two inquests, resulting in verdicts of "death from improper feeding," were held on children in this district during the year 1883. The last lament is that the number of uncertified deaths during the year 1883 is largely in excess of that of the previous year; as against a total of 84, and a percentage of 17·14 in the year 1882, there was for last year a total of 112, with a percentage of 20·2. Surely it would be worth while calling the attention of the Registrar-General to this highly unsatisfactory state of things.

At an adjourned meeting of the Council of the Royal College of Surgeons, held on Thursday last, Mr. Charles Stewart, for many years Curator of the Museum and Lecturer on Comparative Anatomy at the Medical School of St. Thomas's Hospital, was elected Conservator of the Hunterian Museum, in the room of Professor Flower recently translated to the Natural History Department of the British Museum in succession to Sir Richard Owen, K.C.B. We venture to commend the choice of the Council, and to congratulate Mr. Stewart on his well-merited promotion. The energy with which Mr. Stewart devoted himself to his duties at St. Thomas's, and his especial aptitude for the work are well known, and they give earnest of what may be expected of him in his new and enlarged field of work.

FELLOWS IN DISCONTENT.

It is a remarkable coincidence that a single week should have witnessed a movement of discontent—to use the mildest term—on the part of the Fellows of both the Royal Colleges. Such a double movement, headed in each case by men of the highest repute for integrity, must make the present year memorable in the annals of medical progress, even if the greater glory of witnessing the enactment of a State measure of reform be denied it. The movement amongst the Fellows of the College of Surgeons has been as fortunate in securing the leadership of Mr. Pollock, as that amongst the Fellows of the College of Physicians had previously been in obtaining Dr. Andrew for spokesman. Neither of the leaders, fortunately, has hitherto been mixed up in medical politics, and the fact that they have at length been induced to step forth from their position of independence, and to head the two parties of reform, speaks immensely both for the importance of the issues and the prospects of success. Their accession gives to each movement a dignity and forcibleness which neither would otherwise have possessed, and provides some warrant for expecting a further accession of strength. Two men—two statesmen, we may almost say—the acknowledged leaders of medicine and surgery in this country—have now an opportunity of indissolubly connecting their names with the internal progress of their profession, and of adding one more benefit to the many they have already conferred on it. It would be too much to ask them to place themselves at the head of these movements, nor is it necessary. But if it were publicly known that the movement for reform in the College of Surgeons had the support of Sir James Paget, and that for reform in the College of Physicians the sympathy of Sir William Gull, the day of close and irresponsible government would be already past. We have no wish—indeed, it would be presumption on our part to imagine that we have the power—to force the hands of either Sir James Paget or Sir William Gull. But it must be remembered that both are

looked to for guidance in the matter; both are known to be sincerely in favour of liberal, and at the same time conciliatory measures, and their silent support would be sufficient in both cases to ensure the peaceful concession of reforms which must otherwise be fought for, not without risk of rancour.

With much apparent difference there is a singular similarity in essence between the two movements. An attempt has been made—why, we know not—to deny the real principle underlying the discontents at the College of Physicians, and to divert attention into a side issue. But it is plain to everyone, who is willing to look at the matter impartially, that the movement headed by Dr. Andrew is quite as much a popular one, as that which has secured the leadership of Mr. Pollock. Both are protests against irresponsible government, and both ought to be sure of the sympathy of all men who have the true welfare and progress of the profession at heart. It is whispered, but we trust without sufficient evidence, that the leading spirits in the Council of the College of Physicians are indisposed to accept the vote of the 5th instant, in the spirit in which it was meant, and unwilling to avail themselves of the door of retreat from an untenable position which was left open to them. No one wishes the President and Council of the College of Physicians to regard the vote as one of want of confidence. A vast majority of the Fellows wish them to loyally accept the principle which the vote involved, and to continue to hold the important and responsible offices to which they have been elected. If, however, there is to be a compulsory choice between measures and men, we do not doubt that the Fellows will give their preference to the former. It has been astutely attempted to represent the Council as the party of enlightenment and reform, and to condemn the action of the Fellows as the product of narrow selfishness. But the real principle at issue is this. Are the Fellows generally to be allowed the right—in reality, as well as in theory—of deciding who shall be elected to their body, or is the choice of new Fellows to be an inalienable and undisputed appanage of the President and Council? The question whether it is expedient that successful general practitioners shall be admissible to the rank of Fellow, is a minor, though an important one. For our own part, we do not believe that the general practitioners are at all eager for the reflected glory which their body might be supposed to derive from the election to the highest honours of their profession of two or three West-end practitioners. On the other hand, there can be no doubt that the admission of the principle might be attended by serious risks. It may be true that with the present office-bearers such risks would be reduced to a minimum. Hitherto, however, the Fellowship has been awarded for impersonal services to the profession and to science, and the suspicion that it might be possible to gain it by personal services to the chief electors, would be a disastrous feeling to introduce amongst the members of the profession. No office-bearer at the College, we are sure, would ever be tempted to traffic in his influence there, and few general practitioners, we trust, would bring themselves to regard the Fellowship as a purchaseable commodity. But human nature being what it is, it is important to guard against even the suspicion of the possibility of such commerce. We are convinced that the only way to keep the Fellowship really popular amongst the general body of physicians is to preserve it as the reward and rank naturally bestowed on all men of honourable conduct, who have sacrificed their prospects of immediate financial success, and have entered upon that toilsome and thankless period of self-culture, by which alone the true physician is made. Already in the case of several of our younger physicians this reward has been withheld so long, that they are beginning to profess themselves as indifferent whether they obtain it at all, while some of the older and more influential Fellows are complaining that their nominations of candidates for the Fellowship have been silently ignored. This surely is not a desirable spirit to foster amongst the class who must, in any event, always form the backbone of the College. We doubt if the omissions from the late and previous lists could have occurred if the College had adopted the plan recommended to it many years ago, and again advocated in these columns in the number before last. If the practice of the Royal Society had been adopted, and it had been customary to send round a list of all candidates nominated, together with their qualifications, the Fellows would have had an opportunity of seeing how far the Council had carried out, with wisdom and faithfulness, the rather invidious task allotted them. At present, it seems, the Fellows have to take the word of the Council as to the eligibility of half the names recommended for election. The adoption of the plan we advocate, and the infusion of a more living feeling of responsibility, both amongst the Fellows generally, and the office-bearers in particular, are, in our opinion, all that is necessary to restore peace and prosperity to the institution in Pall Mall.

Something of the same sort is needed at the College of Surgeons. If the members of Council had always regarded themselves as responsible to the Fellows who voted for them, in the same way that a member of Parliament is responsible to his electors; if, too, the Fellows had regarded the giving of their vote as a duty they owe to their profession, rather than as a client's duty to his patron, there would have been less need for the present movement. As a matter of fact, the members of Council have been allowed so long to feel that their position is an irresponsible one, that some have come to regard any remonstrances or reminders from their electors as an impertinence. If by any means it can be impressed upon them that their office is a temporary and responsible charge, which in a few years at most they must resign, there will be a hope that they may look further into the future, and take into account some of those currents of thought which are stirring among the younger members of the profession, and which are sure, sooner or later, to make themselves felt even in the Council. It may certainly be expected that this will be one of the first results of the action of the new Association of Fellows. If the Association is largely joined by surgeons of good repute, who will impress upon it moderate counsels and prevent it from playing into the hands of the obstruc-

tives, by making demands which the body of Fellows are not as yet prepared to endorse, we may foretell for it a most happy influence on the government of the College. But if it attempts at one *coup* to revolutionize the whole organization of the College, and to claim forthwith for the Members the same privileges that it demands for the Fellows, it will excite much opposition and will run a risk of losing even the moderate reforms which almost everyone is in favour of. The Association has done wisely in drawing up its first resolutions with a certain vagueness. It will be time enough to demand explicit reforms when its members have had more opportunity of discussion, and can feel their ground more securely. The changes in the constitution of the College, which we would ourselves suggest as reasonable and attainable, though in some respects they outstrip the demands of the Association, are :— First, the election of the President for a term of five years by the Fellows. Secondly, the election of a certain proportion, say one-sixth, of the Council by the Members. Thirdly, the right of both Fellows and Members to be present, and to speak at an Annual Meeting, held for the purpose of considering the Council's report, and ratifying or rejecting any alterations proposed as the general constitution of the College. Fourthly, the election of a certain proportion of non-councillors to the Court of Examiners. In time, of course, we should like to see the Members given a larger voice in the election both of President and Council, but we are convinced that it would be most impolitic to press for this reform until the minor changes suggested have been secured. The Association, in short, should work along the line of least resistance.

CHARITY OUT-AT-ELBOWS.

The number of charitable institutions and societies in London is truly marvellous; hardly a week passes without the formation of some new association intended to work wonders for the improvement socially, medically, or spiritually of the poor of London. Some of these, as for example the various Sanitary Aid Societies, start with very earnest convictions on the part of their promoters, and with carefully devised plans for leading steadily onwards to that grand millennium of health, thrift and knowledge, when they shall die a natural death, their part being played out, their ends accomplished. They are devised to attack some weak point in our system or to wage war with some giant of folly or ignorance, and their whole vitality consists in the energy with which their warfare is carried out. Other minor charities, such as our special hospitals, often owe their origin to less altruistic motives. They spring from small commencements with moderate aspirations and are undertaken full of the zeal and hope inseparable from specialism. They usually start with a Micawber-like trust in the future, the dominant idea being apparently to fix on a local habitation and a name, and then to justify their existence by portentous records of work done in the first few years. On the evidence thus afforded they hope to prove the vast need for their particular sphere of work, and appeal boldly to wider circles for support. But the support does not always come, or perhaps it is large in the first decade, and then dwindles down to a vanishing point. Many institutions commencing with small beginnings get lured on by specious promises to extend their buildings, to add to their number of beds, and to increase their departments with the idea of thus widening their range of usefulness. These devices are by no means confined to special hospitals; they appear to have been in times past the guiding rule of the larger hospitals to which medical schools are attached. Hence we see not only increase in the number of calls on the charitable, but also the need for increased annual subscriptions. It was at one time an aphorism in the management of hospitals that the condition of true prosperity was to be always in debt. It was thought that the aspect of poverty struggling on against adverse circumstances, with noble aspirations for the alleviation of suffering humanity, checked only by coarse considerations of pounds, shillings and pence, must inevitably touch the compassionate bowels of the wealthy, and produce a large roll of annual subscribers, and perhaps also a satisfactory list of kindly remembrances to be made known to all the world by occasional notices in the *Illustrated London News*.

These hopes are proving delusive. Our leading hospitals are, one after another, exhibiting signs of drought, the rain of subscriptions failing, nutrition drying up at its source. We have long been familiar with the announcement that "funds are urgently needed"; and now the struggle for existence appears to be entering a more critical stage. Dinners, concerts, and amateur theatricals are to be no more trusted, the cry for assistance now reaches an almost threatening pitch, foretelling suicide if voluntary contributions are not speedily forthcoming. It is in vain that space has been allowed to be filled occasionally by poorer gentry who aspire to the highest medical aid, without the troublesome expense of procuring it in their homes. The gratitude of such patients has not been found to take a sufficiently tangible form. Attempts have been made in some hospitals to remedy this defect by setting aside certain beds, or by opening whole wards for treatment, in which payment at a fixed rate shall be exacted. At St. Thomas's Hospital this system has long been in force, and the authorities at Guy's Hospital have recently taken a leaf out of the same book, the out-patient department there being now, to a certain extent, self-supporting. But these remedies are not yet sufficiently fashionable to allow of their universal adoption. Institutions loth to follow the lead have lately shown in the daily papers that they still believe in the efficacy of direct appeal made *in formâ pauperis*, and enforced by the threat of diminished usefulness, and the avowal of their determination to strangle the hydra of debt by closing certain wards. Lord Francis Hervey has put the case very plainly with regard to King's College Hospital, stating that the straitened and even necessitous condition of the finances shows that in the absence of a large accession of funds the wards must be partially or even wholly closed. He dwells on the reduction or total cessation of the benefits which the hospital affords to the poor in cases of sickness or accident; but in his appeal, or rather demand, he entirely overlooks the probable detrimental effect of the

course he suggests on the medical school. Nor is this an isolated case; a similar appeal has been recently made by the Lord Mayor on behalf of University College Hospital, and a similar semi-threat of diminished usefulness has been held out. The practical deduction is that the financial position of some of our hospitals has been considerably damaged of late years and reduced to the verge of desperation. The expenses have, in many cases, increased without a corresponding addition to the income; but even this supposition will not explain the whole position. We may attempt an explanation by reference to the arge number of varied calls from minor institutions, by solemn head-shakings over commercial depression, by indirect drainage due to Hospital Sundays and Saturdays; but a more potent cause appears to lie in the unfortunate spirit of antagonism so wilfully created by the spread of the so-called anti-vivisection literature, which tends to discredit all records of usefulness. This last has undoubtedly had a powerful influence in retarding or diverting the normal currents of charity from our larger hospitals, by the dissemination of erroneous ideas as to the studies pursued in the medical schools connected with them. Whatever be the ultimate cause, however, the fact remains that our greatest and most deserving forms of charitable relief are getting reduced to the sad alternative of either working at half-steam, or of closing their doors and putting up an announcement which will surely be a reproach to all who pass by—"No Assets."

THE SUPPRESSED REPORT.

A CONTRIBUTOR who has had prolonged and extensive experience of National and Board Schools, sends us the following remarks on Dr. Crichton Browne's report on education which the Government are being pressed to extract from the pigeon-hole to which they had destined t:—The plain truth of the matter no doubt is, that Dr. Crichton Browne was sent to bless, but has returned to curse, the present system, or rather the way in which it is carried out. He believes that he has collected "strong evidence that over-pressure exists in elementary schools, that it is even now injuriously affecting the health of the children, and that it promises a rich harvest of degeneration hereafter." Such an allegation should be met and disproved if possible, but if not, the sooner it is acted on the better. No good, except perhaps a more convincing proof of the weakness of a position that requires such measures, can follow the suppression of the report at a time when, with very different motives, teachers, parents, and ratepayers are inclined to join in any attack on a system which presses, or is believed to press, heavily on all. A long and practical acquaintance with the conduct of schools, and close association with teachers, has convinced me that this is no mere "scare," that over-pressure does exist, and does act injuriously on the health of teachers as well as scholars, and is moreover inseparable from the present system of payment by results. The present system I say, because, though this is not the place for a full discussion of purely educational questions, there are many conceivable ways of duly rewarding the diligent and conscientious teacher, and of exerting pressure on the inefficient and indolent, besides the regulation of payments according to Section 109. No doubt the unbounded confidence in, and liberality to teachers and managers exhibited in the returns of the great report of the Commissioners in the year 1860, were injudicious, and would soon have been found impracticable; and a system which allowed a teacher to display a few show children, probably of a higher social position than the rest, while the rank and file were neglected, and left to the tender mercies of monitors, was ill-calculated to raise the intellectual condition of the masses. But, on the other hand, that which in principle treats all children of the same age as physically and mentally equal, and makes the grant contingent to a great extent on the number of the passes obtained, offers a strong inducement to check the progress of the really promising, lest by aiming too high they should miss a pass, and to screw and drive the dull ones up to passing pitch. Progress must be constant, regular, and equable, though bodily and mental growth may be slow at first, and later advance by strides. The effects are seen on the teachers no less, I would almost say, than on the taught. I have known numbers of girls and some youths who with every natural aptitude for teaching have broken down in the second or third year of their apprenticeship and taken up with other employments. The children, too, as the annual inspection draws near are worked into a state of nervous agitation, shown by loss of appetite, headache, broken rest, and "examination nightmares." These are facts, but facts to which the statistical method of inquiry is inapplicable. Herein lay the weak point in Dr. Rabagliati's address at the recent conference of the National Union of Elementary Teachers. He could not find any increase in the number of deaths from *nervous* diseases. Of course not. Children do not *die* of such functional derangements, and the greater number of so-called deaths from disorders of the nervous system reported by the Registrar-General are cases of infantile convulsions, which, being due to improper feeding, are dietetic and not nervous at all; while if the pupil teachers to whom I have referred ultimately succumb to consumption, they appear in the return as shop-assistants, dressmakers, and the like. It may be asked how the average child can be overtaxed by the amount of *instruction* conveyed. For the proper appreciation of this, one must bear several points in mind; first the hereditary inferiority of brain power; next the absence of the *education* imparted by the life, the atmosphere of a cultured home; then the lower mental energy possessed and exercised by what we may without discourtesy call half-educated teachers, which will be realised by anyone who will call to mind how, when he was a school-boy, the 'varsity man and the usher taught just the same subjects; next we have the irregularity of attendance so fatal to the progress of the children and exasperating to the teachers, and lastly, all these factors at work in a foul atmosphere and deficient cubic space, the effects of which on mind and body of teachers and children I need not dilate on.

The Library of the Royal College of Surgeons will be closed on the 27th instant for the purposes of the examinations.

REVIEWS AND NOTICES OF BOOKS.

Text-Book of Inorganic Chemistry; by Professor Victor Von Richter. Translated by Edgar F. Smith, A.M., Ph. D. London: Henry Kimpton, 1884.—So numerous are the Text-books on Chemistry passing through the press at the present time that some *raison d'être* is demanded of each newcomer. The little volume before us is not unsupported by internal evidence in favour of its existence. The main object of the work may be stated briefly as follows:—It endeavours (and not without success) to arrange the known facts concerning the properties and composition and reaction of the various chemical elements and inorganic compounds around a great central system or fundamental idea, viz., the "Periodic System of the Elements." The law of periodicity of the chemical elements has been recently affirmed by Medelejeff and Lothar Meyer. It could only have been developed after the determination of the atomic weights of the various elements, and even now there are gaps in the series, which suggest at present undiscovered forms of elementary matter. The tendency of this deduction is to indicate the unity of matter, all the elements as known to us being simply "condensations of one and the same original substance." It has been observed that similar elements, *i.e.*, elements belonging to the same natural group, recur after definite increase in the atomic numbers; thus, there is an interval of 16 between the atomic weights of each of the following couples of elements—Lithium and Sodium—Beryllium and Magnesium—Boron and Aluminium—Carbon and Silicon—Nitrogen and Phosphorus—Oxygen and Sulphur—Fluorine and Chlorine. It is good that this law should be clearly enunciated and described for the benefit of the English student, most of the work connected with it having been done abroad. There are some features of the book which are novel, and, as it seems to us, objectionable—notably the order in which the various elements are introduced to the student's notice. The elements are described in the order of their "atomicities," *i.e.* the monatomic elements are first treated of, then the dyads, followed by the triads and so on. The result of this is that the student has learnt all about hydrogen and chlorine, and the other halogen elements before he has heard a word about oxygen, and is therefore presumably in ignorance of the constitution of the earth's atmosphere. It surely seems more rational to teach the composition of the air, which all are familiar with personally, before describing the properties of those gases which can only be obtained by chemical agency. Again, sulphur being a dyad, whilst nitrogen is a triad element, the student is taught how to make sulphuric acid before he has heard of the existence, formulæ and properties of the oxides of nitrogen, compounds which are most intimately associated with the oil of vitriol manufacture. It is to be hoped, therefore, that this so-called scientific method of classification will not find its way into our text-books, for it is inimical to the *practical teaching* and learning of the subject of chemistry. We would suggest a careful revision of the text, particularly of the numerical expressions in chemical formulæ, since we have detected several errors of the press therein.

The General Practitioner's Guide to Diseases and Injuries of the Eye and Eyelids; by Louis H. Tosswill, B.A., M.B., Cantab, M.R.C.S.; pp. 147. London: J. and A. Churchill. The aim of this little work is to supply the busy practitioner, in as few words as possible, with some information regarding the more common affections of the eye. Diseases of the vitreous, retina and optic nerve, strabismus and errors of refraction are purposely not touched upon. We believe that there is need for some such book, and we consider that Mr. Tosswill's effort to supply it is worthy of praise. Unfortunately in every such attempt the brevity required is apt to interfere with the clearness of description and the safety of advice so necessary. We should be sorry, for example, were the general practitioner to use atropine "whenever there is reason for suspecting disease or injury of iris or lens." The only mention made of the danger of atropine in cases of increased tension or threatening glaucoma is at p. 91, where its employment in predisposed eyes is merely mentioned among the other causes of simple glaucoma. Indeed the method of examination for increased tension described is in itself unsatisfactory. The use of hot fomentations in catarrhal and purulent ophthalmia and in the acute stage of granular lids, and the employment of poulticing "in all cases of dacryo-cystitis" are here recommended, contrary, we venture to think, to the experience of the majority of ophthalmic surgeons. We are given a most meagre description of a disease called "purulent ophthalmia of adults;" of its distinct nature we are still left in doubt. We must protest against the advice given under the head of sympathetic ophthalmia, viz.: "As a perforced stay in a darkened room is very depressing, it is advisable to order a generous diet, with stimulants at discretion." We doubt whether ophthalmia neonatorum can ever be caused by a bright light, and also whether sympathetic ophthalmia is more frequent in childhood. The difficulties of the general practitioner who has had a very imperfect education in ophthalmic surgery are on the whole well recognised. Much of the advice given is most excellent, and we trust that a second edition will further increase the usefulness of Mr. Tosswill's book.

Clinical Notes on Cancer—Its Ætiology and Treatment; by Dr. Herbert Snow. London: J. and A. Churchill, 1883, pp. 96.—This book is written with especial reference to the hereditary fallacy, and to sustain a neurotic origin for most cases of alveolar carcinoma. While we are much inclined to think that the hereditary nature of cancer has been somewhat exaggerated, we can hardly bring ourselves to regard it as a fallacy in the logical sense. That we do inherit peculiarities from our ancestors is beyond all dispute; and if, as a whole, our organism tends to resemble those who have given us birth, it is not difficult to conceive that the individual cells of which we are composed should also tend in their turn to resemble the cells from which they were derived. There is nothing special in the cell elements of a cancer; it is rather their position and arrangement which make them dangerous, and convert them into a "cancer." It is a tendency on the part of the cells to get into a state of rebellion, and to trespass in regions where they are not wanted; for cancer, or, more properly speaking, carcinoma, may be defined as unnatural collections of epithelial cells among the connective tissues. We fail to see the force of the arguments in favour of a neurotic origin: the author himself in one of the most typical forms, the epithelial cancers, dispenses with it, and attributes the growth of this—one of the commonest forms also—to the effects of "lowered healing and recuperative power from advancing age." A study of the disease and its peculiarities can hardly fail, we think, to show that cancer is one and the same thing, histologically speaking, wherever it occurs, and by whatever name it is qualified, and that what is its cause in one place will answer equally well elsewhere. If it be due to neurosis, why is it so localised? Why does it not occur in the organs indifferently? We fancy the book will not do much to establish the neurotic origin of cancer.

On Malignant Disease (Sarcoma and Carcinoma) of the Larynx; by Henry T. Butlin, F.R.C.S. London: J. & A. Churchill.—This dainty little volume is a further contribution to the subject of malignant disease, and is to be regarded as a continuation of Mr. Butlin's former work on "Sarcoma and Carcinoma." It is published separately, we are told in the preface, in order that its author may take an early opportunity of correcting some misapprehensions which seem to exist in regard to the scope and intentions of his first book on this subject. The latter work was in no sense a complete one, and made no pretension to be so; it did not include the whole subject, but only such part of it as had then come within the author's personal experience. It was a *sine quâ non* that all cases should be backed by a careful and adequate microscopic examination; a condition which not unnaturally lessened the total cases which could be utilised, besides altering in some measure the statistics usually accepted up to that time. The present work, based on the same lines, is a further chapter in the history of this important subject, and one which cannot fail to be of great service to those who are interested either in the pathology or the literature of malignant disease.

ABSTRACTS AND EXTRACTS.

PHARMACOLOGY AND THERAPEUTICS.

TRANSFUSION OF BLOOD REGARDED AS A HÆMOSTATIC PROCEDURE.—Professor Hayem, in a recent number of the *Gazette Hebdomadaire*, has contributed the following remarks on this subject:—"I have asked myself how it is that injection of blood into the circulating current produces a hæmostatic effect, and have been thus led to perform some experiments, the principal results of which were published in the *Révue Scientifique*, July 3rd, 1883. But that succinct note which sums up prolonged researches seems to me to be little known, although it contains facts having a direct application to human pathology, and may also be regarded as a contribution to the experimental study of hæmostatic medication. In 1882, I was of opinion that blood in its complete state, including living and active hæmatoblasts, must exert a more active influence than other intra-vascular injections on the coagulability of the blood. The experiments alluded to, in which I have studied in this respect the effects of distilled water, artificial serum, chloride of sodium, serum of the blood obtained from an animal of the same or a different species, natural serosities which are not spontaneously coagulable, the solution of the ferment of fibrine, blood in its complete condition, and defibrinated blood, have led me to the adoption of new views. The most active of these liquids is the serum of the blood; but it is of extreme importance to make the remark that the modification produced in the coagulability of the blood by intra-vascular injections, only becomes evident on the living subject in blood which is stagnant within the vessels. Thus, in the fundamental experiment we observe the singular fact of the almost immediate coagulation of the stagnant blood in a vascular segment, while the general circulation undergoes no apparent disturbance, and to obtain this result, it suffices to introduce into the circulating torrent some cubic centimetres of serum. . . . . In the article referred to will be found a summary statement of the mode of action of the different substances employed; and here it is only necessary to allude to the practical point of view. The possibility of rendering stagnant blood more coagulable, without any prejudice to the economy, is applicable in therapeutics to the treatment of grave hæmorrhages, and perhaps to the treatment of aneurysms. It is, in some sort, the experimental demonstration of the existence of active hæmostatic procedures and agents which, combined with measures for rendering the circulation slower, may favour the formation of coagula in aneurysmatic vessels. In all cases, my experiments having been made with precisely the same liquids that are employed in the different kinds of transfusion, it seems to me certain that the principal practical result of these operations consists in the increase of the coagulability of the blood. It results from this that the indication of transfusion should be drawn, rather from the difficulty of arresting hæmorrhage when the blood is only slightly coagulable, than from the necessity of furnishing a new supply of the liquid to the vascular area. In order to obtain the maximum of useful effects, we should employ serum, that is, the natural liquid which, according to A. Schmidt, contains the largest proportion of that indetermined matter which he has termed the ferment of fibrine. Blood in its complete condition is, however, one of the least active agents. Defibrinated blood, artificial serum, or even distilled water, have a far more powerful action—weaker, however, than that of the serum. But I ought to give the caution here, that if in place of employing on man the serum of human blood, recourse be had to that of the blood of an animal, there would be a risk of producing accidents of the highest moment. The effect of a foreign serum on the circulating blood is to immediately render this grumous, so that it carries along thousands of concretions which, arrested in the minute vessels, give rise in the animals experimented upon to innumerable hæmorrhagic infarcts."

EXCESSIVE USE OF MORPHIA.—The subject of a remarkable case, reported by Dr. Hinckley in the *New York Medical Journal* for March 29th, was a married woman, 26 years of age. Three years ago she was treated for threatened abortion with subcutaneous injections of morphia, gradually increased in strength from the third to the eighth month of pregnancy, when premature labour occurred. She then found herself unable to dispense with the morphia, and continued to use it herself in gradually increasing doses. During a second pregnancy, the daily dose was reduced to ½ grain. Subsequently she again increased it, using 1 drachm of the crystals each week for three months. Then, becoming reckless on the death of her husband, she took a drachm (*sic*) of the sulphate at night, and 25 grains in the morning, and continued this quantity for nine days. Then she reduced the dose to 25 grains *per diem*, which she has continued for some time, occasionally taking an additional 25 grains during the twenty-four hours when she feels particularly "blue." This was her habit when she first came under Dr. Hinckley's observation; and on three successive evenings she dissolved and administered to herself gr. xxv of the sulphate at each sitting, in his presence. Her hair was said to be falling out; constipation was severe, and appetite much impaired; the excretion of urine is increased, sleep is fitful, spasmodic muscular twitchings are frequent during the day; she is easily frightened and irritated, and cannot control her emotions as formerly. There is no uterine trouble, but no menstruation has occurred for twelve months. After eight or ten syringefuls of her daily dose had been introduced *sub cute*, her cheeks were observed to become rosy, her eyes brilliant, her voice softened, and speech became more voluble.

SUBCUTANEOUS USE OF MORPHIA FOR ELDERLY PERSONS.—A writer in the *Boston Medical Journal* (May 1), observes that the fact is not sufficiently borne in mind, that not only children but old people are peculiarly susceptible of the action of anodynes, and that medical men often do not make sufficient reduction in the dose appropriate for an adult. The hypodermic method greatly increases the risk of an overdose, even one eighth of a grain having caused alarming, if not fatal effects. Symptoms indicative of narcosis are often wanting, until the dose is repeated, when they come on with alarming rapidity, and the additional dose cannot be removed as it might be if administered by the stomach. For this and other reasons the writer strongly recommends the use of pills or granules in place of injections. When rapidity of action, or the prevention of the rejection of the opiate by vomiting is imperative, the hypodermic means may be required, but in ordinary practice the use of the pill form is safer and better.

BONJEAN'S ERGOTINE.—It having been stated that Bonjean's ergotine sometimes exhibits poisonous properties, Dr. Bonjean, in a note published in the *Bulletin de Thérapeutique* for April 15th, declares, that in ergotine prepared according to his procedure, such an occurrence is impossible. As he demonstrated to the Société de Pharmacie in 1840, when their gold medal was awarded to him, in ergot of rye there are two distinct principles, viz., ergotine, devoid of all poisonous action, very soluble, and forming a limpid solution without any deposit; and a poisonous substance, insoluble in water, and soluble in ether. Ergotine, deprived of this substance, cannot give rise to the slightest accident. The ill effects, when observed, will be found to have arisen from the ergotine not having been completely deprived of this substance, as M. Bonjean proved in his treatise ("Traité de l'Ergot de Seigle") published in 1846. Ergotine, when isolated by his procedure, may be given to the extent of several grammes *per diem* without inconvenience; but the ergotine of commerce always contains more or less trace of the active poison contained in ergot of rye.

MERCURY IN CROUP.—In the *New York Medical Record*, for May, appears a paper by Dr. Jacobi, mainly devoted to the mercurial treatment of pseudo-membranous

croup. Why he uses this expression, is not clear, for the paper throughout seems to deal with cases of true diphtheria. It is a line of treatment that has been given up in this country almost entirely, after an extensive trial, as being of too lowering a nature, but it seems to have always enjoyed a certain amount of favour in America. Dr. Jacobi recommends the administration of frequent doses of corrosive sublimate, even young infants being able to bear a daily dose of half a grain. He has not met with much difficulty from salivation or stomatitis, nor has he found gastro-intestinal complications to be a source of trouble. When the medicine is not well supported by the mouth, he recommends the inunction of the oleate.

Mercury in the Treatment of Syphilis.—Dr. J. V. Shoemaker finds that mercury by the mouth does not answer in all cases, and cannot be tolerated in some. Under such circumstances, he has obtained rapid and good results from the hypodermic injection of one-tenth of a grain of corrosive sublimate, dissolved in water, deep into the subcutaneous cellular tissue—preferably in the superior or inferior scapular, or in the sacral, region. Abscesses do not follow, and he has never seen any unpleasant consequences. The eczematous condition of the skin, which sometimes follows the inunction of mercurial preparations, can usually be avoided by the use of a hot-air or steam bath before the inunction; it causes the ointment to be absorbed better, thus rendering its application more effectual and preventing irritation of the skin.—*New York Medical Journal*, April 26th, 1884.

Thallium in Syphilis.—As the result of the trials which he has made at the Lourcine Hospital, Dr. Pozzi gives only the following qualified approval of its efficacy:—(1) Iodide of thallium is an alterative. (2) It has produced some improvement in vulvar syphilis, but this amelioration may be imputed, up to a certain point, to rest, cleanliness and improved hygiene. (3) It enters the economy, since it induces some swelling of the gums, and the formation of a white line along their edge, and is also found in the urine. (4) If the amelioration observed in these cases is imputable to thallium, it still occupies a far lower rank than mercury. (5) Supposing that thallium combats secondary symptoms efficaciously, we still have to enquire whether it leads to a durable amelioration, and whether tertiary symptoms are lessened or retarded.—*Gazette Médicale*, March 29th.

White-Lead Paint Treatment of Erysipelas.—Dr. Stirling relates some cases in corroboration of the utility of painting the surface in erysipelas with white paint, as recommended by Mr. Barlow last year. He has chiefly tried this in traumatic erysipelas, of which it shortens the course and relieves the pain almost immediately. In idiopathic facial erysipelas it is a far preferable application to flour or even iodised collodion.—*Australian Medical Journal*.

The Normal Alcohol of the Tissues.—In relation to a controversy that has been going on between Drs. Dujardin-Beaumetz and Perrin in the Academie de Médecine on the elimination of alcohol which has been introduced into the economy, Dr. Béchamp declares that fallacies in the conclusions must exist, inasmuch as the economy itself fabricates and eliminates alcohol, independently of any being swallowed. In proof of this he states that he has found alcohol in the urine after some days of fermentation, as also in the parenchyma of the liver and in the muscular substance, previously to putrefaction. An ostrich's egg also may produce two cubic centimetres of absolute alcohol. It is also produced in the *living* economy from the urine of persons who have completely abstained from its use. Milk also contains it, and even substances totally devoid of saccharine matters. M. Gautier observed, that although Dr. Béhier's observation was foreign to the subject of controversy, which was the form in which alcohol that had been absorbed is eliminated, yet, from his own researches, he could corroborate the statement made, that living tissues do generate alcohol independently.—*Compte Rendu Général*, May 21st.

Infant Feeding in Illness.—The following useful observations, by Dr. Keating, occur in the *Archives of Pediatrics*:—"If a child is so weak and exhausted that it will not digest the mildest form of prepared food, and it is impossible to obtain the breast, it is useless to weaken the condensed milk, or whatever we use, to such a degree as to make it absolutely valueless as a nutrient. The proper thing to do is to give some form of food which requires but little action of the digestive juices, or to prepare the food so that it is partially digested beforehand. I have used for some time, with great advantage, egg-albumen dissolved in water as a food for sick children when the stomach is intolerant of ordinary milk food. I have also observed that gum-arabic water will nourish for a surprisingly long time and allay irritability. Barley food would be valueless in a case of this kind, and pure cow's milk, diluted to resemble as closely as possible the mother's milk, would be regurgitated. In such cases the preparation of milk which has undergone partial digestion by the pancreatic ferment, in an alkaline condition, I have found most useful. The preparation is one which must be made with care, and according to the following directions: Into a clean quart bottle put a powder of five grains of extractum pancreatis, and fifteen grains of bicarbonate of soda, and a gill of water; shake, and then add a pint of fresh milk. Place the bottle in a pitcher of hot water, or set it aside in a warm place for an hour or an hour and a-half, to keep the milk warm, by which time the milk will have become well peptonised. When the contents of the bottle acquire a greyish-yellow colour, and slightly bitter taste, then the milk is thoroughly peptonised—that is the casein of the milk has been digested into peptone. Great heat or cold will destroy this digestive action; so, to prevent all further action when you think that digestion has proceeded far enough, at once place the bottle on ice, or into a vessel of boiling water long enough to scald the contents, and it may then be kept like ordinary milk. The mother should be warned to frequently taste the milk during its digestion, and as soon as the bitter taste is in the *least* apparent, the bottle should be placed on the ice for cooling, as in these cases it is sufficient to partially peptonise the milk. I mention these facts, particularly as, strange to say, I have always failed with it in hospital practice, whereas in private I have had some excellent results, owing, I think, to the extra care in preparation. *Whey* is another admirable alternative in these cases. It may be made with wine, when there is great weakness; but mothers do not often know how to make wine-whey. The proper method is, when the milk is boiling, to put in a wine-glassful of sherry, say, to the pint; and if the curd does not separate, then add more wine until it does. As soon as you notice separation of the curd, add no more wine, but let the mixture boil for a time, until the whey and curd has become thoroughly separated — consuming about five minutes. This should be thoroughly strained. It has been recommended to use *lime-water* in the feeding of infants and young children. I am opposed to its indiscriminate use. I have seen children who could not tolerate even the weak preparation of the pharmacopœia. Undoubtedly at times it may arrest vomiting, as we all know, both in children and adult practice, but I much prefer, when it is necessary, to use an alkali—and if you use cow's milk raw for a young babe, it is always advisable to see that it is made alkaline—to do it with a small quantity of bicarbonate of soda. . . . I have one word of caution to give you in regard to the use of *sucking-bottles*. They are certainly useful as labour-saving machines in early infancy, and when thoroughly cleansed and carefully watched are no doubt indispensable; but I have long come to the conclusion that if you can persuade the mother and nurse to take the time and feed the child that is old enough to manage by the cup or spoon, the word *colic* will seldom meet you in your practice. I am convinced that in institutions for foundlings, if it could be possible to discard the bottle, the percentage of deaths would be much diminished."

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 10TH, 1884.

GEORGE JOHNSON, M.D., F.R.S., President, in the Chair.

Three Forms of Spinal Deformity.

MR. ARBUTHNOT LANE read a paper on this subject. He described three distinct forms of spinal deformity which occurred among labourers who carry heavy burdens. In these the normal curves of the spine were modified to transmit most advantageously the superjacent weight to the pelvis and lower limbs. It was highly probable that there were many other distinct forms besides modifications of the three described. The first form occurred in men whose work consisted in carrying heavy weights on their right shoulders, as draymen. In the case of a man supporting a weight in this manner, it would be found that his spine formed a large curve with its convexity to the right, and that the upper dorsal cervical vertebræ were flexed more than normal. The accompanying slight rotation of the bodies of the vertebræ also affected the position of the ribs. By the continual pressure which the weight exercised on the upper two or three ribs on the right side, they acting as levers on the bodies and transverse processes of the vertebræ, would rotate the upper three or four dorsal vertebræ towards the left, forming a small curve with its convexity to that side. The position of the spinous processes in their single curve was not modified by this rotation to any extent. The formation of the upper curve necessitated a compensatory increase in the deviation of the lower part of the spine from the median line, with an increased rotation of the bodies of the vertebræ. The form of the bodies and intervertebral substances, and the position of the ribs on either side, were altered by these progressive changes. In the lumbar region there was no compensatory curve to the left. The second form is caused by carrying heavy loads on the back. Here the pressure produced compression, changes in the bodies and intervertebral substances of the fifth, sixth, and seventh cervical vertebræ, straightening of the upper two thirds of the dorsal spine, marked and progressive lordosis, and destruction of the bodies and intervertebral substances of the lower dorsal and upper lumbar vertebræ at that part of the spine where the straightened dorsal part joins the lumbar convexity. It also produced a form of spondylolisthesis, due to the yielding of the last lumbar vertebra, or upper part of the sacrum, with the development of osteophytic outgrowth. There might also be some lateral deviation of the upper dorsal spine, due to a greater destruction of one side of the vertebræ in the lower dorsal and upper lumbar regions. The third form was caused by carrying loads on the head. The changes produced were most marked in the cervical spine, where a well-marked lateral curve was produced, with its convexity to the right. The axis and third cervical were frequently fused together, and the bodies and fibro-cartilages of the cervical vertebræ were much modified by pressure, especially in the concavity of the curve and between the upper vertebræ. There could be seen a regular gradation from partial compression of the intervertebral substances to their complete removal, when synostosis of the vertebræ ensued. In the dorsal region there were two compensatory lateral curves, the upper being the best marked, though it was not so definite as that in the cervical region. The convexity of the upper one was directed to the left, that of the lower to the right. The author also showed specimens from the Museum of Guy's Hospital, in which there was osseous ankylosis of the occipital bone with one or more cervical vertebræ. He wished to include these under the same class, as being due to the effect of weight sustained on the head.

MR. HAWARD said surgeons would agree with Mr. Lane as to the first variety. It had been described by many authors, and especially by Americans, and had by them been called "grocers' boys' spine," "porters' spine," &c. Mr. Lane, however, was the first to show and describe *post-mortem* specimens. In his own opinion there were two chief factors, the habitual maintenance of the body in one position, and the use of the muscles of one side, which this position involved. He thought mere weight would not account for rotation; while the origin of the great muscles from the middle line, and their insertion into the transverse processes seemed to him a more reasonable explanation. Formerly it was held that the muscles on the concavity were in action; but, in reality, these muscles were flaccid or passive, while those on the convexity were the active ones. As regarded treatment, he did not think any instrument could be made which would give the needful amount of pressure on the ribs, to overcome the rotation, without producing a sore; the more rational plan was to bring into action the defective muscles by artificial antagonism. He could hardly accept Mr. Lane's proposal that carrying weights, that is to say pressure, had led to the ankylosis which had been described: it did not occur in other joints; a relaxation of the ligaments rather resulted.

MR. NOBLE SMITH thought that rotation of the bodies occurred naturally as the spine became curved laterally. He agreed with Mr. Haward that pressure could not produce ankylosis.

DR. CHAMPNEYS said that in cases of scoliosis in women it was quite usual for the sacro-iliac synchondrosis to be united on the corresponding side.

On a Particular Form of Amnesia—Loss of Nouns.

DR. BROADBENT communicated this paper, of which the following is an abstract:—The paper was a contribution towards the elucidation of the mechanism of speech and thought in continuation of previous attempts in the same direction; the opportunity being afforded by an examination of the brain in a case characterised by the impossibility of saying nouns substantive while all other parts of speech were spoken freely and distinctly. The patient was a gentleman, aged 77 at death, seen at intervals with Mr. Meehan between September, 1878, and December, 1883. He had a slight and fugitive attack of right hemiplegia, with predominant affection of the face and hemianæsthesia, and an affection of speech, which in about a month settled down to the defect, which remained the same for more than five years. During all this time he never uttered a noun, except once or twice by accident, so to speak, and inappropriately, while he could say other words and employ long phrases so long as they did not contain a noun. When he wished for anything he would say, "Please give me the one," and the nurse would make guesses what it was. Other mental functions normal. The lesions found after death were limited to the left hemisphere of the brain, and consisted of small and unimportant depressions in the posterior part of the intra-ventricular corpus striatum, slight diminution in size of the thalamus, complete atrophy of the calcar avis in the posterior cornu of the ventricle, and, finally, an extensive area of softening within the fissure of Sylvius in the posterior half of its extent, sparing altogether the anterior and antero-lateral convolutions of the insula, the third frontal, and the foot of the two convolutions of Rolando, destroying completely the two long posterior convolutions of the island and the subjacent white fibres down to and including the corresponding part of the external capsule, but not invading the lenticular

nucleus (or extra-ventricular corpus striatum), and undermining the supra-marginal lobule and angular gyrus, but not implicating the entire thickness of their axial white fibres or reaching the convexity of the hemisphere. The infra-marginal or first temporo-sphenoidal convolution was remarkably little affected. Another case seen with the late Dr. Frampton was related, similar in all respects except that the patient could not read. No *post-mortem* examination was obtained. The hypothetical mechanism of speech and thought, tentatively advanced by the writer in previous papers, assumed that in the highest or cerebral, as in the lowest or spinal nerve-centres, there were sensory and motor departments, the motor apparatus being educated, so to speak, by the sensory; this education being represented structurally by the formation of groups of cells, through which orderly movements were effected. On the sensory side, it was supposed that in the integration of speech and thought, perceptions from the different perception centres converged upon a common cortical area where they were combined or elaborated into an idea, this idea being symbolised by the associated auditory perception or name. The corresponding motor-centre to this name or idea centre was supposed to be a propositionising centre, in which would take place the mental rehearsal of a phrase or sentence, which was a necessary antecedent to its utterance. Hence if the path from the visual perception centre to the naming centre were interrupted, the sight of an object would no longer recall its name, and a case answering to this condition was related in the first paper on the subject read before this Society. Again, damage to the tract of fibres passing from the auditory perception centre to the naming centre would prevent the patient from understanding what was said to him. The case forming the subject of this paper was supposed to illustrate damage to the communicating tract between the naming and the propositionising centres. The patient could rehearse a phrase in his mind, but the name or noun was not supplied from the appropriate centre. Attention was further called to other remarkable facts in connection with loss of speech.

Mr. Horsley enquired as to the condition of the hippocampal fibres, whether they were destroyed or not.

Dr. Myers rather took exception to the designation of this case, loss of nouns. He contended that the patient made use of the equivalents, viz., pronouns. The sub-division of words, nouns and pronouns was a grammatical rather than a logical one. He enquired whether the power of writing nouns was also lost.

Dr. S. West referred to a case which might be considered as a complement, or a supplement, to this one recorded by Dr. Broadbent, in which the centre that was unaffected in his (Dr. Broadbent's) case was found diseased. There was sudden aphasia with incomplete hemiplegia and hemianæsthesia. At the autopsy, the only lesion found was softening of the marginal convolutions.

Dr. Broadbent replied. He defended his position, arguing that whether the distinction between nouns and pronouns was logical or not, there was a physiological difference, and the power of using the respective words was lost in the case of his patient.

Embolism of the right middle Cerebral Artery producing left Hemiplegia and Hemianæsthesia—Absorption of a large portion of the Right Hemisphere—Death seven years later.

Dr. Seymour J. Sharkey, read the following abstract of the above case.—A woman, aged 34, was admitted into Guy's Hospital on March 8th, 1876, with the history that three weeks previously, being in her ordinary health, she was suddenly attacked with giddiness, faintness, and nausea. These symptoms were followed by twitching of the left side of the body, general convulsions and loss of consciousness. After four days she recovered consciousness, and was then found to be completely paralysed on the left half of her body, and in addition to have lost sight, hearing, taste, smell, and common sensation on the same side. The ophthalmoscope revealed no disease of the fundus of either eye. There was a systolic murmur to be heard all over the cardiac area, but there were no other physical signs of organic disease. Four weeks after the commencement of her illness it was found that the anæsthesia was less marked. Six weeks and a half from the onset sight and hearing were completely restored, and within three months common sensation had returned. The power of motion improved greatly in the left leg, and much more slowly in the arm, and the patient returned home four months from the beginning of her illness, with perfect sensation, both common and special, with her left arm almost useless, but with very fair power in the leg. Seven years after these events the patient was admitted into St. Thomas's Hospital, and there died of cardiac dropsy. At this time she was found to have no loss of sensation, and sight and hearing were equally good on the two sides. The left leg was slightly paralysed, the left arm much more so. At the *post-mortem* examination aortic disease, with general dropsy and the usual chronic congestion of the viscera were found. The left hemisphere of the brain was normal, as were all the cranial nerves. A large portion of the right hemisphere, that part, in fact, which was supplied by the middle cerebral artery, had been almost entirely absorbed. *Conclusions drawn.*—(1) That if the angular gyrus and superior temporo-sphenoidal convolution be respectively connected with sight and hearing on the opposite side of the body their destruction does not involve permanent loss of these special senses. (2) That, contrary to what has lately been asserted, each hemisphere *is* specially connected with the sight of the opposite eye. (3) That sensation, whether common or special, on each side of the body is not so intimately connected with certain definite areæ of the opposite hemisphere as is the case with motion. For the patient gradually recovered from her hemianæsthesia notwithstanding the destruction of those regions, disease of which originally gave rise to it, a fact which shows that other parts, either of the same or of the opposite side of the brain, were capable of completely restoring the lost functions.

In answer to Mr. Horsley and Dr. Broadbent, Dr. Sharkey amplified the details given in his paper (which was read in very brief extract, owing to the lateness of the hour), and stated exactly the parts of the brain which were affected, and defended the conclusions at which he had arrived.

On Albuminuria with Parametritis.

Dr. Matthews Duncan contributed a paper on the above subject, in which he proposed to show the frequent association of parametric phlegmon and abscess with albuminuria, pointing out the absence of this complication in perimetric inflammation and abscess, and in other inflammations and abscesses.

Dr. Champneys said that all those who practised midwifery would feel indebted to the author of this paper for the valuable information it contained, much of which was new. The occurrence of albuminuria, under the circumstances named, would in future cause them less anxiety than it had done in the past.

On the Weight of the Thyroid Body in 84 persons dying from various causes.

Dr. Stephen Mackenzie read a short paper on this subject. The age, sex, and cause of death were given in each case. The author did not attempt to draw any conclusions. He contented himself with a record of facts, thinking they might be useful in connection with myxœdema, which was now occupying considerable attention.

The Society then adjourned until next October.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, MAY 5TH, 1884.

Mr. J. S. TURNER, M.R.C.S., L.D.S., President, in the Chair.

MR. STORER BENNETT showed, for Mr. Balkwill, of Plymouth, the skull of an English black rat, which illustrated in a very remarkable manner the serious results which might happen to rodent animals from the continuous growth of their characteristic teeth, when from any cause their normal antagonism was lost. In this case the two lower incisors had been deflected to the left, and the two upper to the right, so that they did not meet in the usual way. The right upper tooth had described one complete circle and three-fourths of another, and being well inclined outwards, it had not met with any obstacle. The right lower tooth had penetrated the upper jaw and the parts above, and its point projected a quarter of an inch above the highest part of the skull. The left upper tooth, after describing a complete circle, had encountered the front of the upper jaw, which it had penetrated to the depth of one-third of an inch. The left lower tooth had been broken off. The lower jaw was thus quite fixed, and the animal could only have obtained nourishment by suction.

Mr. E. G. BETTS stated that he had found ethylate of sodium very useful for obtunding the pain of sensitive dentine. Before applying it, the dentine should be carefully dried, and the application could be repeated at intervals as the sensibility returned. As it was used by the medical profession for destroying cutaneous nævi, he thought it might be useful for destroying the tooth pulp, but in this respect it had not answered his expectations.

Mr. J. H. MUMMERY read notes of a case of extensive alveolar abscess of obscure origin. The patient, a strong healthy looking young man from Natal, had suffered for more than a year from constant purulent discharge from an opening below the angle of the jaw on the right side, which was a source of great annoyance to him. He had consulted several surgeons, one of whom sent him to Mr. Mummery, with a request that he would remove the necrosed roots of the right lower first molar. This was done, but it did not affect the abscess. Six months later the patient returned in the same condition, and now consented to a further careful examination of the teeth. The second molar had a small cement filling in the crown, but was firm and not tender on percussion; the third molar also appeared quite healthy, but on drilling into the former, pus escaped. The tooth was at once extracted and the sinus healed within a week. The patient stated that the tooth had cost him between 400*l.* and 500*l.* in travelling expenses and surgical fees.

Mr. BETTS then read a paper entitled "Observations on the Teeth of certain Rodents," in which he disproved the statement first made by Professor Helgendorff, and since copied into other works, that the incisors of the Leporidæ had a complete investment of enamel, and showed that the thin transparent layer at the back of the incisors of hares and rabbits was really continued from the cementum and could clearly be demonstrated not to be enamel. This, although apparently a small matter, was of more importance than appeared at first sight, since the supposed fact had been held to show that the Leporidæ were in this respect a missing link between the Rodents and the other Mammalia, whilst in reality the exact relations of this large class to the rest of the Animal Kingdom must still be considered an open problem.

The results of Mr. Betts' observations were confirmed by Messrs. A. Underwood and Chas. Tomes. The latter also remarked on the obscure zoological relations of the Rodent class, and suggested that some of the missing links might possibly yet be supplied by a careful study of the Marsupials.

NORTH-EASTERN HOSPITAL FOR CHILDREN. — At the annual meeting, held on the 13th instant, it was reported that the yearly expenditure had exceeded the receipts by nearly 1,000*l.*

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE VI.

FOOD.

Malt Extracts—Infants' Foods.

Malt Extracts.

THE separation of certain principles from plants and animals which have properties identical with, or analogous to, those of the secretions of the salivary, gastric and pancreatic secretions, has laid the foundation of a large and growing industry.

Pepsin, ingluvin, papaine, are prescribed by physicians, but have scarcely, as yet, become truly popular; on the other hand, malt extract has, so to speak, acquired a hold upon the taste of a beer-drinking nation, and is bought largely with and without medical sanction.

Malt extract is not only an extremely digestible carbohydrate food, but when successfully manufactured, the diastase has very considerable power, both in converting starch into sugar, and also in emulsifying certain fats. During the last two years the writer has been in the habit of examining from time to time all the well known extracts of commerce. The experience thus obtained has shown that, so far as active diastatic properties are concerned, a great many are absolutely inert, while even in the best there is considerable variation. It is impossible, from the appearance or taste of a malt extract, to form any idea of its diastatic power; actual testing is necessary. The writer uses a very simple process. An indeterminate quantity of the sticky extract is carefully weighed and dissolved, so as to equal exactly five per cent.; every 20 c. c., therefore, is equivalent to one gramme; a one per cent. decoction of *potato starch* is made by boiling ten grammes of the starch to as perfect a solution as possible, and after cooling making it up to a litre. 100 c. c. of the starch solution, and 20 c. c. of the extract solution are then placed in an incubator, set at 98·8° F., in separate beakers, for a quarter of an hour, and when they are thus brought to that temperature, the solutions are mixed, and allowed to react; at the expiration of every minute a drop is spotted on to a white plate, and tested with iodine. The blue colour will disappear within ten minutes if the extract is very active. An extract that, tested in this way, gives a blue colour at the end of 25 minutes is, as far as diastatic power goes, useless.

Of the some eight or nine samples of extracts exhibited at the Exhibition, five have been received, and may be briefly noticed.

M. Hoff's Extract of Malt is a liquid of the appearance and consistence of stout; it is surcharged with carbon-dioxide, and the taste is rather agreeable. It contains 13 per cent. of solid residue, which has all the appearance of malt extract; the ash is two per cent.

Fifty c. c. of the liquid freed by agitation from carbon-dioxide, were digested for twelve hours in the incubator with 100 c. c. of the potato starch solution, but at the end of that time it still gave a strong blue with iodine; hence the diastatic power of the extract is practically nil. At the same time it is a pleasant, nutritious drink, and may be used in those cases where the feeding, and not the alcoholic, properties of stout are thought necessary.

Squire's Super-diastatic Malt Extract.—Messrs. Squire, we believe, have only recently manufactured malt extract. It will be remembered that the firm, last year, at Knightsbridge, successfully competed against their older rivals, and obtained the only medal awarded at the smaller and less pretentious Health Exhibition. It was, therefore, thought well to examine their present exhibit closely, so that if the excellence of the first attempt were maintained, the composition of their extract might serve usefully as a standard of comparison.

The extract is of a fine pale colour, and extremely stiff, so that it is with considerable difficulty poured out of the bottle. It contains 18·3 per cent. of water, 2·3 per cent. of ash, 3·4 per cent. of maltose, and ·64 per cent of nitrogen.

In the incubator, one part of the extract wholly converted one part of potato starch within ten minutes. It is therefore an active extract.

Hordeum (Loeflund & Co.).—In consistence and colour this extract almost precisely resembles Squire's malt extract; the amount of water, maltose, and nitrogen, is also the same.

In the incubator, one part of malt extract digested one part of potato starch in 20 minutes; the extract has, therefore, diastatic powers.

Maltine.—This is very different in appearance from either Hordeum or Squire's preparation, for it is so fluid that it may be readily poured out. This fluidity is certainly very convenient, for the manipulation of the more inspissated products, on account of their glutinous nature, is difficult; on the other hand, the more fluid an extract, the less likely it is to preserve the diastase unchanged; slow saponifications go on, and the nitrogenous molecule splits up. Maltine contains 28 per cent. of water, and 2 per cent. of ash. One part of the maltine digested one of potato starch within 15 minutes; it is therefore of good diastatic activity.

Kepler Extract of Malt.—A sample of this extract, exhibited by Messrs. Burroughs and Wellcome, was of a fine pale colour, and in consistence intermediate between the stiff extract made by Messrs. Squire, and the very fluid "maltine." It was found to be diastatically active, one part of the extract digesting one of potato starch in 13 minutes.

Infants' Foods.

There is only one exact way, free from error, by which to judge of the different merits of the various infants' foods, and that is, for some impartial observer, in no way connected with the manufacture of the foods, to feed a number of children of different ages with known quantities, and tabulate the gain or loss of weight, state of health, &c. Some of the foods advertised and largely sold are so opposite in character and principle, that it is impossible for both classes to be equal in value.

The exhibits of Infants' Foods mainly fall under the following heads:—

(1) Milk Foods.
(2) Malted Farinaceous Foods.
(3) Soluble Carbohydrates.

1. *Milk Foods.*—Under this division fall all condensed milks and such products as Nestlé's Milk Powder, which consists of a union of milk with farinaceous substances, or Squire's Milk Powder, which consists of pure milk evaporated to dryness in a vacuum pan, and then powdered. It is perhaps not generally known that however low a temperature is used in evaporating milk, it is yet impossible to dissolve up the dry residue so as to form a liquid in the same physical state as the original milk. The residue when heated with water is only partly soluble; the milk sugar dissolves, the albumen dissolves, but part of the casein remains insoluble and the milk fat is not disseminated throughout the liquid in the same way as is the case with fresh milk. Hence attempts to simply preserve a concentrated, not a dessicated, milk have their *raison d'être.* A tin of condensed milk derived from the Swiss Dairy Company (Uttwyl), is a good example of this method of preservation. The milk is perfectly fluid, and is simply the sterilised and concentrated milk; every 100 parts by weight we find to contain 35·8 of milk solids; so that 100 parts are equal to 297 of ordinary good milk (which should contain 12 per cent. of solids). The label on the tin states that anyone who wishes to "obtain a rich creamy milk is to add three parts of warm or cold water to one part of the condensed milk." If these directions are followed, instead of "a rich creamy" milk the consumer will get a fluid equal to the thin poor stuff retailed by unscrupulous London milkmen on Sundays, when they have little fear of the food inspector. The directions should be for one part of the milk to be made into three by the addition of water.

2. *Malted Farinaceous Foods.*—These foods are all compounded of flour, previously baked or not, and malt or malt extract. When treated with warm water the diastase of the malt is supposed to act on the other starches and render them more assimilable.

Some idea of the relative diastatic value of the foods may be obtained by allowing a known weight of flour to be acted upon by water in the cold for a given time, and the matters extracted in this way estimated, while a second experiment is made on the same lines, but the food is in this experiment placed in the incubator. The difference of the weights of matter extracted in the cold and in the warm have a direct relation to the diastatic activity of the food.

Messrs. Squire have brought out an infants' food, which is a fair representative of the type under consideration. The chemical examination of this food gives the following results:—

	Per cent.
Water	6·50
Fat	1·45
Nitrogen, soluble in cold water ·45 Nitrogen, insoluble in cold water ·61	1·06
Amount of substances soluble in cold water (of which 1·87 is sugar).. ..	18·04
Amount of substances soluble in water by digesting for three hours in an incubator at 98·8 F.	37·76
Ash..	1·07

The constituents which have not been directly determined in the above analysis are mainly starch and cellulose.

On mixing the food with water a very pleasant malt-like odour is evolved; the incorporation of the constituents is evidently very complete, and the food appears to be precisely as represented in the statement printed on each package.

The infants' food so largely sold by Messrs. Savory and Moore appears to be very similar to that of Messrs. Squire. A sample gave us 5·10 per cent. of water, 1·52 per cent. of fat, cold extract 5·90 per cent., digested extract 25·20 per cent., ash 1 per cent.

Mr. Ekin also shows an infants' food, made, so far as we can see, on precisely similar lines. The food contains water, 5·4 per cent.; total nitrogen, ·67 per cent.; cold extract, 8 per cent.; digested extract, 23·0 per cent.; ash, 1 per cent.

We think it would not be right to express any opinion as to the relative merits of these three foods. Although the quoted analyses show that there are minor differences, our knowledge is not yet precise enough to say whether it is better for "infants'" food to have a high diastatic power or a low one.

3. *Soluble Carbohydrates.*—In Mellin's food for infants there is quite a new departure, for it contains no starch at all; everything has been digested. The manufacturer evidently considers that the infant's digestive organs should remain idle while his maltose and dextrin dialyse into the circulation. The food is practically dextrin, maltose, diastase, and a little phosphate.

We question very much whether it is good to feed an infant wholly on liquid nourishment. In the most natural of all diets for our very young, human milk, it is well known that the acid in the stomach almost immediately precipitates the casein, and judging from analogy, food containing solid particles is far more likely to afford the necessary stimulus to digestion than a bland, neutral liquid. We should, therefore, always advise that Mellin's food be given as an addition to a milk dietary, rather than as the sole article of nourishment. But, as before stated, the only way to form a correct judgment on the various foods is by experiment on infants themselves.

CONFERENCE ON THE SPREAD OF INFECTIOUS DISEASES.

THURSDAY, JUNE 12th, 1884.

Dr. ALFRED CARPENTER in the Chair.

[Abstract.]

DR. W. N. THURSFIELD read a paper on the spread of infectious and epidemic disease by means of milk, a somewhat abridged version of which appears in another column.

Dr. W. H. CORFIELD, Medical Officer of Health for St. George's, Hanover Square, next read a paper with regard to the manner in which infectious diseases were spread. We

were able, he said, to prevent the spread of infectious diseases exactly in proportion to our knowledge of the ways in which they were spread. It has been shown by Chauveau and others, from examination of liquids containing poisons of some of these diseases, that the poison exists in the form of solid particles, and is not in solution in the liquids; and other phenomena attending these diseases, especially the non-diffusibility of the poisons as shown by the limited extent of the infecting area around an infected person, leads us to the same conclusion. These poisons, then, are "particulate;" they are also, without doubt, organized substances, and many of the phenomena that they exhibit induce us to believe that most, if not all, of them are organized, that they are, in fact, living things, capable of growth and reproduction. The atmosphere was a most universal medium or vehicle of communication for the poisons of these diseases, though the poisons of some of these diseases were much more readily conveyed directly by the air than were the poisons of others, and, indeed, some of them produced an evident and characteristic smell in the air around the patient. The smell of small-pox had been long known, and no doubt was referred to by the great Arabian physician, Rhazes, who, in his first chapter, entitled "Of the Cause of the Small-pox, and how it comes to pass that hardly anyone escapes the Disease," told us that it was chiefly prevalent "in pestilential, putrid, and malignant constitutions of the air." The poisons of some of these diseases were more especially conveyed in the foul air of sewers and drains. This was the case with enteric or typhoid fever, the poison of which was chiefly, if not entirely, discharged from the body by means of the intestinal canal, and with diphtheria. Among other *media* or vehicles of infection he mentioned the clothing of persons not themselves suffering from the disease, the agency of laundries, public conveyances, wall papers, letters, food, and drinking water (especially in the cases of cholera, enteric or typhoid fever, with dysentery in hot climates) contaminated by sewer air getting into cisterns from overflow or waste-pipes connected with soil-pipes or drains. Diphtheria had not been usually recognised as a disease conveyed by means of drinking water, but some interesting examples brought by Dr. Browning before the Society of the Medical Officers of Health, made it very evident that, occasionally at any rate, this disease was spread in the manner in question. There could, however, be no doubt, that while enteric fever was generally contracted by means of polluted water and occasionally by means of polluted air, diphtheria was generally contracted by means of polluted air and only occasionally by means of polluted drinking water.

In the course of the discussion on the papers, Professor De Chaumont expressed regret at the nihilist attitude which had been taken up by medical men connected with the sanitary department of the Government in India respecting the origin of cholera. Without accepting as proven the results of the investigations of Koch, he said that the loss of this discovery to the British nation was due very largely to the obstruction put in the way of investigation by that department.

Dr. Fleming, speaking of the extent to which the flesh of animals that had suffered from tuberculosis or phthisis was sold in our markets, said the condition of our slaughter-houses was a disgrace to civilisation. Both slaughter-houses and dairies, &c., should be under constant and efficient inspection.

Dr. Priestly urged the importance of more care on the part of heads of families after the occurrence of scarlet-fever and measles in their families. A more conscientious regard for others should be made a matter of education in public morality.

Mr. J. Cleland Burns said that when the community had once been convinced that the rates and taxes would be lowered by looking after the health of the population, sanitation would be properly carried out.

The Duke of Buckingham expressed his hope that these conferences would be fruitful of good by awakening public interest in matters so essential to the well-being of the community as those under discussion.

The Chairman made some suggestive remarks with regard to the hybridising of disease germs and the production under conditions favourable to the development of the hybrids of new forms of disease. With regard to the spread of epizootic diseases, he read an Order of the Privy Council just circulated, which gave powers to prevent the danger of the carrying of infection by drovers and others having to do with cattle. One beneficial effect which might be gained from these regulations would be the better understanding on the part of the people of the conditions under which disease was spread, and of the precautions necessary to prevent the dissemination of infectious diseases.

The proceedings closed with a vote of thanks to the chairman, moved by Professor De Chaumont.

CONFERENCE ON THE NOTIFICATION OF INFECTIOUS DISEASES.[1]

Friday, June 13th.

The Earl Fortescue in the Chair.

LIVERPOOL MEDICAL INSTITUTION

The Chairman said, that in the promotion of sanitary reform affecting the widespread work of sanitation, it must be inevitable that individual liberty and the rights of property must to a certain extent be interfered with for the public good. He should listen attentively to the arguments for and against a novel, but by no means unprecedented, extension of that interference in the shape of compulsory notification of the existence of infectious diseases. It was for the advocates of any compulsory interference with individual liberty, or with the rights of property, to justify exceptional legislation for that purpose. Liberty itself was so very precious a possession, that it ought not lightly to be curtailed. The confidence in the security of property was so indispensable to the development of self-denying thrift and industry, and retention of capital, that it ought not to be lightly shaken or alarmed. It was better to tolerate a certain amount of inconvenience, of evil, and even of suffering, than to interfere by legislation with liberty and property. Capital was really the wage-fund, and it was liable to be scared away on the slightest cause of alarm. Too constant official interference tended to the enervation of the national character, and to render men helpless and unfit for liberty, after they had been too long looked after and done for, and unfitted them for the duties and responsibilities of freemen. Moreover, the evil of enlisting general sympathy against the law by any prematurely stringent enactment and enforcement of regulations, tended to diminish the sympathy for, and support of, law generally; it caused the law to be looked at not as a general friend and protector, as it had long been in England, but rather as an unpopular king. Multiplied official interference required multiplied officials, and multiplied offices to be filled were apt to be accompanied by even disproportionately large numbers of office-seekers, and though competitive examination tended to diminish the number, and to eliminate those intellectually least qualified, yet the training for those examinations was a preparation rather for the work of verification or distribution than of production. In these days of slackness of business and want of prosperity in commerce, he should dread anything which tended to augment the body of distributors of a diminished produce, and of unofficial verifiers of a diminished number of transactions. In spite of the judicious establishment of competitive examinations, a very large proportion of official patronage would inevitably fall into official hands, and much of it was likely to be given away for political purposes. In conclusion he suggested that speakers should confine themselves to the following points:—(1) What success had attended the system in regard to the proportion of cases notified to the total number of cases. (2) What success in stamping out diseases it had led to. (3) What amount of hospital accommodation the sanitary authorities of the place had provided for infectious diseases, and to what extent it had been made use of.

[1] Held under the auspices of the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Parkes Museum of Hygiene.

Dr. Alfred Hill, Medical Officer of Health for Birmingham, read a paper on "The Notification of Infectious Diseases: its importance and difficulties." In order, he said, to prevent the spread of disease, and the possibility of one or two cases developing into a widespread and fatal epidemic, a knowledge of the existence of first cases was indispensable. There was only one way of obtaining such knowledge, and that was by means of notification, the making it known to the proper person or authority. The experiment of voluntary notification tried in Birmingham failed. Of the 300 practitioners in the town only 118 had ever voluntarily notified. Notification, to be of real value, must not be optional but imperative; it must not be subordinated to individual interest or caprice, because it was then too uncertain, too impartial, and frequently too late. It was a remarkable fact that out of 38 towns in Great Britain which had availed themselves of compulsory notification, 34 had adopted the system of direct notification by the medical attendant, while 30 of these required notification also by the occupier; in three of them only did it rest with the medical man to notify indirectly or to the occupier, so that the dual system was found to be by far the most in favour. The relation between notification and cost of hospital accommodation, without regard to other considerations, seemed to him a matter of the greatest importance, and the fact should not be lost sight of that the main value of a hospital for infectious diseases was to treat first cases and prevent epidemics, and not to treat thousands of cases which might, with proper care, have been prevented.

Dr. Alfred Carpenter, in a paper entitled "The Right of the State to Enforce Notification, and the best method of doing it," gave a succinct account of the growth of opinion with regard to this question among medical men and sanitarians. If towns, he remarked, having the compulsory clauses in operation were not able to show better things than could be shown in those places in which only a moral obligation to disclose existed, he thought it must be evident to those who wished to prevent us trusting too much to a paternal Government that we had better steer clear of too much compulsion, and trust a little more to moral obligations. It was found by experience that as good results had been obtained in districts in which notification was voluntary as in those places in which it was compulsory; indeed, the incidence of infective disease was higher in Huddersfield, in Bolton, in Edinburgh, and in Greenock than in a number of places in which there was no compulsion upon medical men, showing at once that compulsion had not extinguished the diseases which were proposed to be stamped out by it. He would rather that the neglect to perform a moral duty should be dealt with by the medical licensing authorities or by the Medical Council than that it should be made a penal matter, to be dealt with in a court of summary jurisdiction by those who would not always be able to see the motive for the prosecution or the medical bearing of the case, and the possible differences of opinion which would sometimes arise, and which would be best dealt with by men of high standing in the medical profession.

Mr. W. Blyth thought those who wished for compulsory notification had to make out a very strong case before it could be obtained. He believed that a case had been made out for some alteration, though he could not go so far as the readers of the papers. Some medical gentlemen imagined that compulsory notification would altogether stamp out infectious disease, but this was a fallacy, as many persons were every day walking about the streets, suffering from scarlet fever, who did not even know they were suffering from the disease.

Dr. Carter (Liverpool) did not believe that the private Acts now in force would work without serious modification, and that they did not control the spread of infectious disease more than it was controlled in other towns without such Acts. In support of this view he quoted statistics, to show that in towns where the Act was in force the death-rate had not been in the slightest degree reduced.

Dr. Armstrong (Medical Officer of Health of Newcastle-on-Tyne) maintained that since the Act had been in force in Newcastle, great improvement in the health of the inhabitants had taken place.

Mr. Wm. Young (Secretary to the Society for the Compulsory Abolition of Vaccination) objected to compulsory notification, and suggested, that as zymotic diseases were being stamped out by the present sanitary arrangement, things should be tried a little longer before legislation was attempted. He believed the bogey of infection had been raised up to serve some purpose.

Dr. Mahomed thought the system of notification and isolation would not answer; for, in the case of measles, the most infectious period was during the first four days, when the disease could not be diagnosed. Typhus had been almost banished by improved sanitary arrangements, and with regard to small-pox, that could be prevented by vaccination. Isolation might do good in the case of scarlet fever, if every case could be dealt with, but many persons had it without knowing it.

Dr. Dudfield having spoken in favour of the notification of infectious disease, and referred to the good effects of the system as carried out in Kensington,

Mr. Jas. Bailey (Secretary to the Vigilance Association) urged that a good case must be made out before such a measure was attempted to be forced on the poorer classes, for he did not think sanitary officers would attempt to meddle with the rich. He agreed with Dr. Carter that the laws which were in force in certain towns, compelling compulsory notification, had not resulted in any marked diminution of disease.

Dr. N. Hardy, as a medical man, objected to the principle of compulsory notification, and referred to the great plague of London, when compulsory notification was necessary, as an instance that it would not stamp out disease.

Professor Corfield said it was absurd to say that the notification of epidemic diseases did not prevent the spread of disease. In such cases as measles, schools could be closed directly the disease was known to exist; and only recently this disease was checked in St. George's, Hanover Square, in this way. He objected to the liberty of the subject to spread infectious diseases.

Dr. Charles West testified to the immense advantage of notification, but did not go into the question of compulsion. He had seen the evil arising from concealment in a health resort in the South of France, and the diminution of contagious disease where notification was practised.

Dr. Taaffe (Brighton) said he could have prevented the spread of typhoid fever amongst 26 out of 91 families supplied from one milk shop, if the first case, which arose from contaminated milk, had been notified to him. He was in favour of compulsion.

The Chairman, in summing up the discussion, said, it seemed to him that a case had been made out for compulsory notification of disease, but after the difference of opinion which appeared to exist amongst the medical profession, he did not think a case had been made for compelling medical men to notify cases which came under their notice, but that the responsibility should lie on the householder. As an old sanitary reformer, he could not conceal from himself that the fullest notification did not always prevent the spread of zymotic disease, whilst in other cases, where good conditions and cleanliness prevailed, such diseases did not spread.

Professor Corfield moved a vote of thanks to the chairman, which terminated the proceedings.

GENERAL CORRESPONDENCE.

HYDRO- AND PYO-SALPINX.

[To the Editor of the Medical Times.]

Sir,—Mr. Lawson Tait is mistaken in supposing that I mix up two classes of cases, namely those which he says rupture and cause a general peritonitis, proving fatal, and those which he asserts wander about unrelieved from hospital to hospital. On the contrary, ever since Mr. Tait's statement last November, at the Obstetrical Society, that

several of the cases he had operated on had been under treatment previously at Guy's Hospital, I have been sharply on the look-out for both classes of case. Hitherto I have not yet come across a single fatal case. I have come across two cases which I believe to be distended Fallopian tubes. One was the case I referred to in my letter, which got well without using the knife, and the other is now attending in the out-patient department at Guy's under my care.

Mr. Tait says he is never sure of his diagnosis until he has the diseased appendages outside. Then, has Mr. Tait operated in some cases and found on getting the appendages outside that they were not diseased at all? If not, if Mr. Tait has operated in sixty or seventy cases, and in every instance has found the appendages diseased, does not this show that he at least has hitherto been able to diagnose these cases with absolute certainty? If so, does Mr. Tait claim a monopoly in the ability to diagnose them? I said I had cured a case under my own care, and Mr. Tait doubts the diagnosis. Fortunately, I had the advantage of the opinion of my colleague, Dr. Galabin, who kindly saw the case with me two or three times, and who quite agreed with me in the diagnosis of the case.

Mr. Tait, without having seen a single case now attending at Guy's, has "not the slightest doubt but that there are fifteen or twenty such cases attending the out-patient department of Guy's Hospital," under my care, "at the present time." I myself, after having examined the cases, am of opinion that there is only one such case, the one referred to above, and she is getting better without using the knife, although it is more tedious than it would otherwise be, because she cannot at present obtain the necessary rest.

Finally, allow me to point out that when I asked Mr. Tait for the names of those patients on whom he had operated, and who, he said, had previously been under treatment at Guy's, it was no answer whatever to give me the three aliases of a woman who, he states, was in hospital at Woolwich, and at the Samaritan and Soho hospitals, and *he thinks* at Guy's, and who had also been under the care of this, that, and the other practitioner. It is enough for me that she has never been in Guy's, so far as I can find out.

Thus far, therefore, Mr. Tait's statement about some of his cases having been under treatment at Guy's remains unsubstantiated.

I am, Sir, yours, &c.

St. Thomas's Street, S.E., June 16th, 1884. P. HORROCKS.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

[To the Editor of the Medical Times.]

SIR,—Permit me to state that at the meeting of Fellows, held on Thursday, the 12th inst., Mr. John H. Morgan, 68, Grosvenor Street, and Mr. Bruce-Clarke, 46, Harley Street, were appointed Joint-Secretaries. All communications with regard to the Association of Fellows should for the future be addressed to them.

Yours faithfully,

Plymouth, June 14. PAUL SWAIN, F.R.C.S.

MEDICAL NEWS.

UNIVERSITY OF CAMBRIDGE.—At a Congregation held on the 12th instant the following degrees were conferred.

Doctors of Medicine:—

D. Macalister, St. John's; G. Parker, St. John's; G. N. Pitt, Clare; R. S. Taylor, Pembroke; R. M. Wolfenden, Christ's; C. Y. Biss, Downing.

Bachelors of Medicine:—

G. H. Bolton, Trinity; W. Pash, Pembroke; W. W. E. Fletcher, Caius; G. B. Hoffmeister, Caius; S. Jones-Bateman, Caius; J. Scott, Caius; G. F. Welsford, Caius; J. F. S. Whittingdale, Caius; H. W. Pigeon, Christ's; H. Groom, Magdalene; W. Groom, Magdalene; F. H. Wigmore, Magdalene; H. W. M'Kenzie, Emmanuel; J. H. H. Manley, Emmanuel.

Bachelors of Arts:—

H. J. Davies, Trinity; P. L. C. F. Renouf, Trinity; W. P. Graham, Caius; S. Palmer, Trinity Hall.

Bachelors in Surgery:—

G. D. Bolton, Trinity; G. N. Pitt, Clare; E. Jones-Bateman, Caius; H. W. Pigeon, Christ's; J. H. H. Manley, Emmanuel.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 12th, 1884:—

Stephen Lawson Deeble, 6, Crescent, Mornington Road, N.W. Alfred Samuel Gubb, 52, Newman Street, W.; Ralph Hodgson, St. Bartholomew's College; William Edward Gillson Jackson, 13, Addington Street, S.E.; Ithel Penderel Llewelyn, 26, Brunswick Square, W.C.; William Edward Newey, Parade House, Dudley; Harry Tuck, Brighton Road, Surbiton; William George Weaver, 10A, Great Smith Street, S.W.; James Balls Woolby, 18, Woburn Place, W.C.

The following gentleman also on the same day passed the primary professional examination:—

Evan Jones, London Hospital.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examinations for the Licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, June 9th, 10th, 11th, and 12th, the following candidates were successful:—For the *Licence to Practise Medicine*—

Charles Robert Battersby, Blackrock, Co. Dublin; James Joseph Bolger, Dublin; Frederic Brentnall, Stockport; Charles Edward Fitzgerald, M.D. Univ. Dub., Dublin; Diego Gannon, Dublin; John King Irwin, Dublin; John Bently Mann, Manchester; Francis Bernard Manning, Ballyhaise, Co. Cavan; William Cox Neville, M.D. Univ. Dub., Dublin; Andrew Joseph O'Flanagan, Waterford; John Patrick O'Riordan, Bruff, Co. Limerick; John Clarke Soady, Dublin; Edward Churchill Stack, Monaghan.

For the *Licence to Practise Midwifery*—

Charles Robert Battersby, James Joseph Bolger, Frederic Brentnall; William Walter Fenton, M.B. Univ. Dub., Dublin; Diego Gannon; James Sullivan Green, M.B. Univ. Dub., Dublin; John King Irwin; James Lennox, M.D., R.U.I.; Francis Bernard Manning, William Cox Neville, M.D. Univ. Dub.; Andrew Joseph O'Flanagan, John Patrick O'Riordan, Edward Churchill Stack.

The following Licentiates in Medicine of the College, having complied with the by-laws relating to membership, pursuant to the provisions of the Supplemental Charter of December 12th, 1878, have been duly enrolled Members of the College:—

John Molony, *Lic. Med.* 1874, Collooney, Co. Sligo; Lambert H. Ormsby, *Lic. Med.* 1869, 92, Merrion Square, W., Dublin.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Her Royal Highness Princess Louise, Marchioness of Lorne, has promised to distribute the prizes to the students, and to open the new wing of the Hospital, containing 70 additional beds, on Wednesday, July 2nd.

NAVAL MEDICAL SERVICE.—Deputy Inspector-General of Hospitals and Fleets G. Mason, M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

INDIAN MEDICAL SERVICE.—The Queen has approved of the admission of the undermentioned Surgeons:—J. J. Pratt, R. Shore, M.D., Bengal; W. B. Bannerman, H. Thomson, Madras; C. J. Sarkies, Bombay. The Queen has approved of the retirement from Her Majesty's Indian Military Forces of the undermentioned Officers:—Deputy Surgeon-General R. H. Perkins, of the Bengal Army; Surgeon-Major F. W. A. De Fabeck, of the Bengal Army; Surgeon-Major T. Holmested, of the Bombay Army.

UNIVERSITY OF CAMBRIDGE.—The following examiners have been appointed:—Dr. O. Sturges, Emmanuel; Dr. N. Moore, St. Catherine's; and J. M. Duncan, M.D. (Aberdeen), for the third M.B. examination during the ensuing year. J. N. C. Davies-Colley, and C. Heath, F.R.C.S., in surgery during the ensuing year, F. S. B. F. de Chaumont, M.D. (Edinburgh), W. H. Corfield, M.D. (Oxon), A. Carpenter, M.D. (London), and Dr. H. Airy, Trinity, in state medicine for the ensuing academical year.

BUBONIC PLAGUE NEAR BAGDAD.—The *North German Gazette* publishes intelligence from Teheran, dated 26th ultimo, stating that according to reliable reports received there an epidemic had broken out on the right bank of the

Tigris, near Bagdad, which quickly proved fatal to those attacked. The disease was supposed at Teheran to be bubonic plague, but its existence had long been kept secret by the Turkish authorities. In consequence of the outbreak the Persian Government had forbidden the departure of pilgrims for Kerbela, and had established a sanitary cordon on the frontier. It was also reported that Turkey had now given orders for the imposition of quarantine.

Office of City Coroner.—At a meeting of the Court of Common Council, held at Guildhall on Thursday week, the Court proceeded to the election of Coroner for the City of London and the borough of Southwark, rendered vacant by the death of Mr. W. J. Payne. There were twelve candidates, viz.: Mr. W. Adam Burn, Dr. A. Chune Fletcher, Mr. B. E. Greenfield, Dr. T. S. Horsford, Mr. S. F. Langham (Deputy Coroner for the City and Coroner for the Duchy of Lancaster), Mr. H. B. Mugliston, Mr. G. F. Roumieux (Coroner for West Surrey), Dr. A. B. Thompson, Dr. J. C. Torry, Dr. Wynn-Westcott (Deputy Coroner for Central Middlesex), Mr. G. P. Wyatt (Coroner for Surrey), and Dr. G. E. Yarrow. The candidates were first reduced to two—Dr. Horsford and Mr. Langham—by show of hands, and then a poll of the members was taken. For Mr. Langham 95 votes were recorded, and for Dr. Horsford 85, and Mr. Langham was declared duly elected.

Aberdeen Sick Children's Hospital. — From the stimulus given by Princess Beatrice opening a Bazaar last autumn, in aid of its funds, such a sum has been realised which enables the Committee of Management to proceed with alterations and additions. Valuable adjoining property has been acquired and plans have been carefully drawn up for the addition of several wards and the enlargement of the present. A fever ward is to be added, which will be of great service to the community. On the whole the changes made will make it a very comfortable and commodious institution.

Aberdeen Royal Infirmary.—At the adjourned conference held by a special committee with the hospital staff, to enquire into increased hospital expenditure and household management, it was stated that nearly one-half of the patients admitted to the infirmary are not properly certified as in every respect suitable persons for being treated in the institution, and it was resolved that no one in future would be admitted to the benefits of the hospital unless passed as suitable by the superintendent. The question of increased ventilation, deficiency of baths, the granting of a salary to the residents, and a pay ward for private patients, was fully discussed, but no definite line of action was fixed on.

Combe Lying-in Hospital, Dublin.—On Thursday week the Lord Mayor of Dublin inspected this hospital and subsequently presided at the annual meeting, when Dr. S. R. Mason, the master of the hospital, reported that during the past year the resources of the hospital had been taxed to their fullest extent, as the large number of 624 patients were admitted to and treated in the labour wards of the hospital, whilst 158 patients were treated in the wards reserved for the treatment of diseases peculiar to women. This was the largest number of patients that had been admitted into either department of the hospital since its foundation in the year 1826. In the extern maternity 1,818 poor women were attended at their own homes. The attendance at the special dispensary amounted to 2,191, and at the general dispensary to 6,010. The hospital is much in need of funds.

University College Hospital.—A public meeting in aid of the funds of this hospital was held at the Mansion House on Monday, the Lord Mayor, M.P., presiding. A circular issued by the hospital stated that this being the 50th or jubilee year of the existence of the hospital, which was opened for the reception of patients in 1834, the committee were anxious to celebrate the event, not only by clearing off the serious load of debt, over 8,000*l.*, with which their work was at present hampered, but also by raising a large sum for permanent investment as a Jubilee Endowment and Building Fund. The present financial position of the hospital was as follows—Annual necessary cost of maintenance, 19,000*l.*; reliable income from all sources, 6,500*l.*; annual deficiency to be provided for, 12,500*l.* This deficiency during the last few years had only been partially covered by donations and legacies, and the unfortunate result had been the forced sale of stock and the consequent diminution of dividends. A letter was read announcing a bequest to the hospital of 1,000*l.* under the will of the late Dr. Alexander Tweedie. Various resolutions were passed, and in the course of the meeting it was announced that contributions which had been received amounted to nearly 3,000*l.*, and that a gentleman had given 1,000*l.*, the interest of which was to be applied to sending children to convalescent homes. It was also stated that the medical staff had in some instances given up half their fees, and in one case the whole.

Vaccination and Small-pox.—In view of the recrudescence of small-pox in the metropolis, the National Health Society have forwarded to the several metropolitan boards of guardians and sanitary authorities copies of a pamphlet which they have prepared on the subject of vaccination, and which they suggest should be left by the local officials, or by special temporary officers to be appointed, at each house within the several districts. This plan has already been carried out with marked success in certain metropolitan unions, and the general adoption of a similar course would no doubt lead to equally beneficial results. The pamphlet in question has received the honour of revision and amplification by the Local Government Board, who have, moreover, sanctioned in a number of cases the repayment of the expenses of its distribution out of the Metropolitan Common Poor Fund. The pamphlet may now, therefore, be fairly regarded as an official publication on the subject of which it treats. The society suggests that it would tend greatly to encourage vaccination and revaccination if the plain facts on the subject were brought home to every householder by a copy of the pamphlet being left at his door; and it would, moreover, materially assist the vaccination officers in the discharge of their often difficult duties. With the praiseworthy object of assisting as far as possible in the limitation of the epidemic, the society offers to supply copies of the pamphlet, as revised by the Local Government Board, at the cost of printing. In view of the extension of small-pox in the metropolis, it is clearly important that the local authorities should give the widest publicity in their districts to the actual facts on this very important question.

Infanticide in France.—A report has recently been made to the President of the French Republic, in which it appears that in 1882 legal proceedings were taken with respect to 171 cases of infanticide, 19 abortions, and 177 cases of concealment of birth or exposure of infants. The report explains that the proportion of acquittals for each of these crimes amounts to 42, 55, and 61 per cent. respectively. As we may be morally certain that nearly every one of the accused was in reality guilty, the enormous proportion of acquittals must seem inexplicable to those not intimately acquainted with French society. But the search for the proof of parentage is forbidden by the French law, and French juries, knowing that the law gives no protection to betrayed and abandoned women, cannot be made to convict, even when the guilt is patent.

Population of Denmark.—There are but three countries less thinly peopled than Denmark, viz.: Norway, Servia, and Montenegro. At the census of 1880 there were enumerated only 1,980,259 souls, comprising also the Faroes (11,220), Iceland (72,445), Danish India (33,763), and Greenland (about 10,000). The urban population amounts to 516,742 and the rural to 1,463,517. Perhaps 36,210 should be deducted from these last as residing at commercial places, and therefore to be considered as civic inhabitants. The population at the census consisted of 1,007,427 women and 972,832 men, the disproportion seeming to be chiefly due to emigration, which removes three men for every woman. In Copenhagen there were 20,000 more women than men, although at the beginning of the century the men were in the majority.—*Journal de la Société de Statistique*, May.

A French Annual Congress of Surgery.—A corresponding member of the Paris Société de Chirurgie having proposed that an annual congress of French surgeons should be held, the matter was referred to a committee, the report of which Professor Pozzi read at a recent meeting of the Society. This observes that by the side of the German annual congress "which makes such an effort to absorb everything," it is very desirable that a great scientific centre of the surgeons of France and of countries speaking French, should annually assemble. In this way all surgeons speaking the French language will be brought together from Alsace-Lorraine, Switzerland, Belgium, Canada, &c.; while invitations may also be addressed to those of other countries willing to make their communications in French, and such would doubtless be eagerly received in Holland, Sweden, Russia, Poland, Hungary, &c. The only part the Société de Chirurgie intends taking in the matter is to frame the rules and regulations for starting the new congress. M. Desprès was the only objector to this new project and this arose from his belief in the very slight utility derivable from the congresses now existing in such abundance. He strongly advised the Société de Chirurgie to have nothing to do with setting it on foot; but with this exception the Society was unanimously in favour of the scheme.

The Anti-Vivisection Question in America.—In our last number, a statement made by Dr. Weir Mitchell, when proposing a resolution to the Medical Society of the State of Philadelphia against legislative interference with experimental investigations, to the effect that "the Indian Government has sent snake-poison to Philadelphia, and money also, to secure investigations, not being able to have such researches made in England," has been erroneously reported. The facts are thus stated by Dr. Mitchell, in a note to the *Philadelphia Medical News*, May 24th:—"Last year, at my request, Mr. Frelinghuysen, Secretary of State, addressed Her Majesty's Indian Government in regard to our researches on venoms. A sum of money was devoted to aid in collecting the poison of Indian serpents, and orders were issued to certain Army Surgeons in regard to the matter. As a result, we have been able to continue the researches which Lauder Brunton was successfully prosecuting until the Vivisection Act put an end to his work."

APPOINTMENTS.

Awdry, W. R., M.B.—Resident Surgical Officer to the Genera Hospital, Birmingham.

Brown, H. H., M.B.—Visiting Surgeon to the Chester General Infirmary, *vice* F. J. Salter, L.R.C.P., resigned.

Cockell, E. S., M.R.C.S.—Medical Officer to the Hartlepool Friendly Societies' Medical Association, *vice* J. J. Weir, M.B., resigned.

Davies, G. H., L.R.C.S., L.R.C.P.—Honorary Ophthalmic Surgeon to the Blackburn and East Lancashire Infirmary.

Evans, E. R., L.R.C.P., M.R.C.S., L.S.A.—Honorary Surgeon to the Hertford General Infirmary, *vice* Woodhouse, resigned.

Ogle, A., M.R.C.S.—Resident Medical Officer to the St. Marylebone General Dispensary.

Stewart, A., L.R.C.P.—Honorary Surgeon to the Borough Hospital, Birkenhead, *vice* S. Spratley, M.D., resigned.

Stoker, G., M.K.Q.C.P., M.R.C.S.—Surgeon to the Hospital for Diseases of the Throat and Chest, Golden Square.

Thomson, St. Clair, M.B.—Resident Medical Officer to the Queen Charlotte's Lying-in Hospital, *vice* J. B. Woolby, L.R.C.P., resigned.

VACANCIES.

Borough of Gateshead.—Medical Officer of Health. (*For particulars see Advertisement.*)

Boscombe Provident Infirmary, Bournemouth.—Resident Medical Officer. Salary, £60 per annum, with board, &c. Candidates must be duly registered, and unmarried. Private practice prohibited. Applications, with copies of recent testimonials, to be sent to the Honorary Secretary, before June 28th.

County and County of the Borough of Carmarthen Infirmary.—House Surgeon. Salary £100 per annum, with board, lodging, fire and light. Candidates must be registered to practice both in medicine and surgery, unmarried, and free from the care of a family. They must have a knowledge of the Welsh language, and will be required to enter into an agreement not to practice in the County of the Borough of Carmarthen for a period of five years. Applications, with testimonials, as to ability and character, to be sent to Mr. H. Howells, 11, Morley Street, Carmarthen, on or before July 12th.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £80 per annum, with board and lodging. Candidates must possess a duly registered qualification. Applications, with testimonials, to be sent to Mr. F. P. Flood, 2, Lodge Street, Leeds, on or before June 23rd.

Liverpool Dispensaries.—Assistant House Surgeon. Salary to commence £108 per annum, with apartments, fire, gas, and attendance. Candidates must be duly qualified. Applications, stating age, with certificates of registration, and testimonials, to be sent to the Secretary, Liverpool Dispensaries Office, 34, Moorfields, Liverpool, not later than June 24th.

Queen's College Birmingham.—Professorship of Anatomy. Salary £262 10*s.* per annum. Applications with testimonials, to be sent to the Secretary, Joseph Lewis, 21, Paradise Street, Birmingham (from whom further particulars can be obtained), on or before June 30th.

St. George's and St. James's Dispensary.—Honorary Physician. Candidates must be either F. or M.R.C.P. Lond., or Graduates in Medicine of one of the Universities of the United Kingdom. Applications, with diplomas and testimonials, to be addressed to the Medical Committee, at the Dispensary, 60, King Street, Golden Square, W., not later than June 25th; and candidates must attend personally at the Dispensary on June 26th, at 4.30 p.m.

West London Hospital, Hammersmith, W.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London, and not practising as apothecaries. They are requested to attend a meeting of the Medical Council on July 1st, at 3.30 o'clock p.m. The election will take place on July 7th. Applications and copies of testimonials to be sent to the Secretary not later than June 30th.

York County Hospital.—Assistant House Surgeon. Salary, £50 per annum, with board and residence. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons in the United Kingdom, registered under the Medical Act, and unmarried. Applications, stating age, accompanied by testimonials, to be sent to Secretary's Office, 5, New Street, York, on or before June 21st.

DEATHS.

Branson, C. L. S., M.R.C.S., L.R.C.P., at 30, Tavistock Road, Westbourne Park, on June 16th, in his 37th year.

Brown, J. J. A., M.D., at Grantham House, Grantham, on June 13th, aged 76.

Bush, T. G., M.R.C.S., L.S.A., at Glenbourne, West End, near Southampton, on June 11th, aged 69.

Dixie, W. F., M.D., in London, on June 12th, aged 57.

Goodeve, H. J. H., M.D., F.R.C.P., F.R.C.S., J.P., at Cook's Folly, near Bristol, on June 17th aged 77.

North, John, M.R.C.S., J.P., at 8, Warrington Gardens, Maida Vale, on June 6th, in his 75th year.

Tuck, F. S., M.R.C.S., at 4, Batsford Road, St. John's, New Cross, S.E., on May 24th, aged 35.

West, W. C., M.R.C.P., at Yarnton Lodge, Malvern, on June 15th, aged 73.

NOTES, QUERIES, AND REPLIES.

THE PROPOSED MEDICAL SECTION OF THE POSTAL MICROSCOPICAL SOCIETY.

[TO THE EDITOR OF THE MEDICAL TIMES.]

Sir,—A few weeks ago you very kindly inserted from my President a letter on the above subject, but as I fear that some slight misapprehension was inadvertently conveyed to some of your readers, I beg you will allow me the opportunity of stating briefly the object which I hope to attain by the formation of this new Section, which is this:—The means of furnishing Members of the Medical Profession with such slides as they are naturally most interested in, and such notes in relation thereto as will not only anatomically describe the slides under observation, but will, where practicable, give a full history of the cases from whence they were taken, duration of the disease, the methods of treatment adopted, and every other matter of interest likely to prove of any educational value to all succeeding Members. To accomplish this, it is proposed that every Member shall send to the Hon. Secretary for circulation six slides (or any multiple of six), with full descriptive notes thereon, to be written in the book, or books, provided for that purpose, and each Member receiving the same, will be asked to add all that he can in further elucidation of the various subjects under discussion. Boxes containing twelve slides will be circulated at regular dates, and in such a manner that each Member should receive one at fortnightly intervals. When each set of slides has been seen by all the Members, it will be returned to the original contributors, who will be asked for a fresh supply, and that each series (or set) may circulate for a whole year, it is necessary that at least *Fifty* Members be enrolled. Several have already sent in their names. As the fees for the Medical Section (separately) will be the same as for the General Section, it is thought desirable that the two Sections shall run concurrently; the first year's subscription, therefore, will carry on to the 30th September, 1885, and will after the first year become due on the 1st October in each year. The first session will commence as soon as a sufficient number of slides have been received.

Members of the Medical Section will be at liberty to join the General Section also, on paying *half* annual subscription extra. A copy of the *Journal of Microscopy* is presented to every Member quarterly, as published.

I am, Sir, &c.,

Alfred Allen, Hon. Secretary.

BROMIDE OF POTASSIUM.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—If your readers will always bear the following in mind, they will do much towards conserving *minds:* Bromide of Potassium = *softening of the Brain.*

I am, Sir, &c.,

W. Walnut Lane, Germantown, Philadelphia. GEO. H. CLARK.
June 6th, 1884.

IODIDE OF SODIUM.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Observing that you make mention, as a matter of quite recent interest, of the preference given by Dr. Berg for Iodide of Sodium over Iodide of Potassium, will you allow me to state that in my work, "The Throat and its Diseases," published in 1878, I, at page 110, recommend the Sodium Salt in preference to that of Potassium, for the very reasons quoted by Dr. Berg in your issue of this date.

I am, Sir, &c.,

36, Weymouth Street, Portland Place, W. LENNOX BROWNE.
June 14th, 1884.

COMMUNICATIONS RECEIVED—

Dr. WYNN WESTCOTT, London; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; THE SECRETARY OF THE INTERNATIONAL HEALTH EXHIBITION, London; Dr. TAAFE, Brighton; Mr. FRANCIS VACHER, Birkenhead; Dr. CLARK, Ongar; THE EDITOR OF THE TUNBRIDGE WELLS ADVERTISER, Tunbridge; THE EDITOR OF THE BRITISH AND COLONIAL DRUGGIST, London; THE SECRETARY OF THE HOSPITALS ASSOCIATION, London; THE SECRETARY OF THE LOCAL GOVERNMENT BOARD, London; Dr. NORRIS WOLFENDEN, London; Dr. J. S. BRISTOWE, London; OUR VIENNA CORRESPONDENT; Prof. CORFIELD, London; Mr. J. WICKHAM BARNES, London; Dr. C. F. TAYLOR, Philadelphia; Mr. BRUCE JOY, London; Dr. LUDWIG LOEWE, Berlin; Dr. W. N. THURSFIELD, Shrewsbury; Dr. LENNOX BROWNE, London; Dr. G. H. CLARK, Philadelphia; Dr. HORROCKS, London; Mr. J. APPOINTMENTS FOR THE WEEK.

Friday, June 20 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Professor Sir Henry Thompson will deliver his Fifth Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

Saturday, June 21.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, June 23.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m.—Professor Sir Henry Thompson will deliver his Sixth Lecture "On some Important Changes in Connection with the Surgery of the Urinary Organs."

Tuesday, June 24.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND, 8 p.m.—The following Communications will be received:—Prof. Flower, LL.D., F.R.S., President, "On the Size of the Teeth as a Character of Race;" O. A. Shrubsole, Esq., F.G.S., "On Flint Implements found at Reading;" S. M. Curl, Esq., M.D., "Phœnician Intercourse with Polynesia;" M. J. Walhouse, Esq., "A Hindu Prophetess;" J. E. Greenhill, Esq., "Exhibition of Palæolithic Implements recently found in the north-east of London."

Wednesday, June 25.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, June 26.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

ON THE METHODS OF DIAGNOSIS.[1]

By BYROM BRAMWELL, M.D., F.R.C.P., Edin.

Lecturer on the Principles and of Practice of Medicine, and on Practical Medicine and Medical Diagnosis in the Extra-Academical School of Medicine, Edinburgh, &c., &c.

THERE is no doubt a tendency on the part of every teacher to over-estimate the importance of that particular department of medical science with which he has to do. But bearing in mind that tendency, I can with confidence affirm that there is no subject which is of more importance to you than that one, the study of which we commence to-day.

In the capacity of general practitioners, that honourable career to which most of you will probably devote your lives, you will have to practise all branches of the profession, but the majority—the great majority—of your patients will be suffering from *medical* diseases. Obviously, therefore, it is of the greatest importance, both for your own success, and also for the welfare of the public, that you should enter into practice with a sound knowledge of *medicine*, and with the confident assurance that you feel yourselves able both to recognise and treat *medical* cases.

But to acquire even a moderate knowledge of the *medicine* of to-day is no trivial undertaking. The subject is of vast extent—it is probably the largest in the whole curriculum—it is ever changing from day to day, and is continually and rapidly increasing. The preliminary difficulties which the student has to overcome in making himself familiar with the mere methods of clinical investigation, are much greater in the case of medicine than in the case of surgery. The surgeon has to deal chiefly with external parts; and is able to employ sight and touch as his most important means of clinical investigation. The physician, on the other hand, is more particularly concerned with the internal organs. He has sometimes to fall back upon more elaborate means of investigation, and has not unfrequently to rely upon hearing as his chief aid to diagnosis and, as you will soon find, it is very much more difficult to train the ear and to teach and learn sounds, than to educate the senses of sight and touch. Add to these circumstances (and there are others which I might have mentioned) the fact, that the portion of the curriculum which is at present devoted to *medicine* (clinical and systematic) is far too short, and I think I have said enough to show you that you have no light task before you. It is essential, therefore, that you should lay down for yourselves a well considered plan of study; and that you should apply yourselves to the work with all that diligence and perseverance which have always characterised the students of this great school, and which are specially characteristic of the Edinburgh

[1] Being an introductory lecture to the Author's Summer Course of Practical Medicine and Medical Diagnosis, in the Extra-Academical School of Medicine, Edinburgh.

student of to-day. And this leads me to speak of the circumstance which induced me to give this course of lectures, and of the kind of instruction which you will derive from it. I well remember the feeling of bewilderment and uncertainty with which I commenced the study of *medicine* (medicine as distinguished from surgery) in the wards of our Royal Infirmary, now a considerable time ago; and although I had the inestimable advantage of attending the *clinique* of one of the most distinguished clinical teachers of that day—I refer to the late Professor Sanders—it was some time before I could fully profit by his instruction. I often thought, at that time, how useful to me a course of medicine, such as I propose to give you during the present session, would have been. On coming back to Edinburgh, I put my student notion into practice, and I am glad to know, from the large number of students who are present here to-day, that the course is appreciated by you. Let me add that no effort on my part shall be wanting to make the lectures a thorough and complete success. It is a serious thing to be a teacher, and as each year comes round, I feel more deeply sensible of my responsibility. The primary object of a teacher of medicine is, of course, to impart sound instruction to his students, to convey to them such knowledge as will be of real use to them in their future career as practitioners of medicine, not forgetting altogether their present needs and the requirements of the Examining Bodies. But while this is his main object, that teacher would, in my opinion, fail in his duty to his profession, and would fall far short of what my ideal of a teacher ought to be, who did not endeavour, both by precept and example, to arouse their enthusiasm, and to send them forth into the world, not only able, but ardently desirous of making original observations, and of adding to the common stock of knowledge. I earnestly hope that *I* may succeed in arousing *your* enthusiasm, that I may number among my class some, at least, who will attain to future distinction, and that all of you may look back upon this course of lectures as not the least profitable and pleasurable part of your curricula.

These lectures will constitute a preliminary Course of Medicine. The instruction I propose to give you will be as practical as possible, and will relate more to the diagnosis than to the treatment of disease.

I shall, in the first place, describe to you the method of investigating and recording medical cases (*case-taking and case-recording*). I will next take up the examination of the various systems and organs in detail. Under this head:

(1) I will briefly recall to your memories the medical anatomy and the physiology of the organ under consideration.

(2) I will describe to you the clinical methods by which we ascertain the condition of that organ; giving you a detailed description of the instruments employed in the investigation of medical cases, their mode of application, and the information to be derived from their use.

(3) I will point out to you the normal physical signs, *i.e.*, the signs appreciable to the senses (unaided and aided) of the physician, which result from the physical condition of the organ in its healthy state.

(4) I will consider the pathological physical signs, *i.e.*, the signs which result from the physical conditions of the organ when diseased.

(5) I will detail to you the more important abnormal sensations or symptoms, which the patient feels as the result of such pathological conditions, taking care to explain, whenever it is possible, the relationship of the symptoms to the lesion, *i.e.*, the manner in which the lesion produces the symptoms.

(6) I will then tell you how the different disorders and lesions are to be distinguished (Diagnosis and Differential Diagnosis). This will constitute a considerable, and an important part of the course.

(7) If time permits, I will indicate the points to which attention is to be directed in forming the prognosis.

(8) And I will enumerate the chief indications for treatment.

A course of lectures of this description would be very incomplete without practical instruction. I shall therefore divide the class into small sections for practical tutorial work; and will in this manner give each of you the opportunity of practising percussion, auscultation, &c., and of applying the different instruments to the living patient.

The kind of knowledge which I shall do my best to communicate to you in this course of lectures is, in my opinion, of the first importance to the student. As I have already said, medicine is a vast subject, and it is quite impossible for any of you to hope to *master* (*i.e.* to get a real, sound, and personal knowledge of) all the details of individual diseases during the brief period of the curriculum. The time has, I think, now come either for extending the period of study—an extra year devoted to the final subjects would be highly advantageous—or if that cannot be done, it would be better, I think, to limit the subjects required for the purposes of examination—more especially some of the preliminary subjects—and to demand a thorough knowledge of the great principles of medicine, and of all the common and important medical affections, rather than an imperfect smattering and cram knowledge of the whole.

While, therefore, I am of opinion that too much detailed knowledge of rare and obscure affections should not be required for the purposes of a pass examination, I think, and think most strongly, that no student should be allowed to enter practice who is not thoroughly versed in the details of clinical investigation and of clinical work, and who is not practically familiar with all the more important instruments, such as the laryngoscope, the ophthalmoscope, the electric battery, &c., which are used in medical research. Unless you acquire this sort of knowledge during your student days, you will probably never acquire it; and unless you possess this knowledge you will not be so well fitted as you otherwise would be to add to the science and progress of medicine. Some of you may perhaps say, but we intend to be general practitioners, and what opportunity shall we have of making original observations. Believe me—and I speak from some years' active experience as a general practitioner—your opportunities will be great. To mention one point only, the general practitioner sees disease from its commencement, he has consequently better opportunities of ascertaining its causation than the hospital physician to whom cases are brought in their later and more developed stages. Hence the general practitioner is much more likely to discover the means by which diseases can be prevented, and I need not tell you that "prevention is better than cure." If you enter into practice with the desire and determination to observe and record clinical facts you will find your work a pleasure, you will treat your patients much more satisfactorily, and you will get reputation and practice more quickly than if you looked upon your profession as a mere business and matter of routine.

Such then is the plan and scope of this course.

Now, the great object of the physician is to cure disease; or if, as unfortunately frequently happens, that be impossible, to relieve suffering and to prolong life. Treatment is therefore the point which we must always keep in view.

In order that our treatment may be rational and scientific, it is necessary in the first place to ascertain exactly, or as exactly as the present state of medical

science will allow, the morbid condition or conditions which are present; in other words, to make a full and exact diagnosis.

A diagnosis is not a mere guess, but is *a logical conclusion based upon the facts of the case.* In making a diagnosis your aim should be not merely to give a name to the disease, but to take into account the special features which it presents in the individual case under observation, to ascertain, if possible, the exact character and extent of the lesion—for it is only after we have got this information that we are in a position to treat the affection satisfactorily and to judge of its probable duration and course.

The mere naming of the disease is, as a rule, an easy matter. Sometimes, however, even that is impossible, owing to the fact that in some cases the grounds for forming an opinion are insufficient (the symptoms and physical signs are imperfectly developed); and that there are probably some diseases whose clinical features are as yet unknown. I can give you no better illustration of the fact that the mere naming of the disease is not a diagnosis, than by referring to the term "heart disease," which is so frequently used both by the laity and also by the profession. Under this name are grouped many different conditions, and many different degrees of the same affection. Some forms of "heart disease" are of the gravest possible significance; others may continue for years, but are apt to terminate in sudden death; others, again (and in this class we meet with cases in which the heart's action may be markedly deranged, and in which the sounds may be replaced by murmurs), are of comparatively trivial importance, some of them having no tendency to cause sudden death or to materially shorten life, and others being readily amenable to treatment. To include all these different conditions under a common term, which to both the lay and to the professional mind is of very serious significance, and to diagnose them all as "heart disease," is obviously highly unscientific and improper. In making a diagnosis in such cases, the physician endeavours to determine whether the cardiac derangement is organic or functional; and if it be organic, what is the exact character and extent of the lesion.

To correctly appreciate the special features of any given case, to gauge the extent and tendencies of the morbid process, is much more difficult, and demands the highest skill of the experienced practitioner. In order to arrive at a correct conclusion on this point, it is necessary to be well acquainted with the characters which the disease usually presents, and to take into account not only the special features which are manifested in the individual case under observation, but also the constitutional peculiarities, and the pathological tendencies of the patient. It is impossible to insist too strongly upon the importance of studying the individual characteristics and peculiarities of each and every patient who comes under observation. Students, whose knowledge of disease must necessarily be in great part gained by listening to systematic lectures and reading systematic text-books, are very apt to ignore the personal element or "personal equation" as it has been fitly termed, and to regard their patients as so many cases of this or that disease (pneumonia, typhoid, mitral regurgitation, for example), rather than as separate individuals, each with his special time and constitutional peculiarities to which, so to speak, the disease is engrafted or superadded. The fallacy of such a mode of looking at disease becomes obvious enough when one gets into practice, and is, to some extent counter-balanced by clinical teaching, but it is necessary to emphasise it. The systematic lecturer and systematic writer must necessarily describe types of disease, rather than individual cases, and in order to be clear and intelligible, he must necessarily draw in his outlines sharply and clearly; a very little practical experience will show you that the hard and fast lines of the type pictures are being constantly departed from. Let me beg of you, then, to study the individual characteristics and peculiarities of your patients, and while sparing no pains to make yourselves well acquainted with the type pictures which systematic teachers and lecturers describe, to study disease as it occurs in nature; it is only by the unwearied observation of disease at the bedside, and the study of the special features of each individual case, by looking, in fact, not only at the lesion, but also at the individual affected by that lesion, that you can hope to acquire that broad and comprehensive grasp, without which no one can be a truly good practitioner. It may be impossible, owing to the very nature of the case, even for the most experienced and accomplished physician to make an ideal diagnosis of the sort I have just indicated in every case, but a minute and exact diagnosis should always be aimed at. In support of this proposition, I cannot do better than quote to you what Dr. Gowers says in speaking of the diagnosis of the diseases of the spinal cord. He writes:—'A tendency is sometimes observed among many members of the profession to undervalue diagnosis. Our business is to cure disease, as far as we are able, and a fear has been expressed lest our study of exactness in diagnosis should be at the expense of precision in treatment.' 'It matters little,' it has been said, 'whether your diagnosis of a diseased condition is minutely exact, if you are able to cure it.' This is true, but a very superficial study of practical medicine will show that much diagnosis, which is of no direct avail for treatment, is essential for the diagnosis which enables us to treat successfully. Of all organs there are some diseases for which we can do little, there are others for which we can do much; but unless we are able accurately to distinguish the diseases of each class, we shall be unable to apply our skill where it will be effective. Moreover, there are examples of the same form of disease, in some of which the diagnosis is easy, in others most difficult. The diagnostic knowledge which is superfluous in one case, is essential in another.'[2]

I hope I have now impressed you with the idea, that you should in all cases do your best to make a full and exact diagnosis. Now, in order to attain this end it is necessary—

1. To have a sufficiency of facts.
2. To have the facts correctly observed and noted.
3. To give due weight to the individual facts, and to the manner in which they are grouped; and to draw the logical conclusion therefrom.

The facts of the case include—

(1) Certain *preliminary particulars*, viz., the age, sex, occupation, etc., of the patient.

(2) *The previous history*—
- (*a*) Of the present attack.
- (*b*) Of the patient's former health.
- (*c*) As to his social surrounding, habits, etc.
- (*d*) As to his hereditary tendencies (the family history).

(3) *The symptoms*,[3] *i.e.*, the morbid sensations experienced by the patient.

[2] "The Diagnosis of Diseases of the Spinal Cord," p. 1.

[3] Symptoms are usually divided into subjective and objective. *Subjective* symptoms are those abnormal sensations, such as pain and numbness, which are experienced by the patient, but which cannot be appreciated by the physician. Under the term *objective* symptoms, are included such obvious abnormal conditions as jaundice, swelling of the feet, &c., which are perceived by the physician, but which do not require any physical examination, properly so called, for their detection. The *physical signs*, again, are such facts as dulness on percussion, which the physician elicits by physical examination. It is preferable, I think, to include the objective symptoms and physical signs under the common term of *facts observed by the physician*. Jaundice, swelling of the feet, and other conditions which are detected by the aid of sight, are just as much physical signs as râles or murmurs which may sometimes be observed by the unaided ear.

(4) *The facts observed by the physician*, including the objective symptoms and the physical signs.

The correct observation of the facts of the case.—In my next lecture I shall speak in detail of the manner in which the facts of the case are to be elicited (case-taking), but I may mention here, that the particulars on which the diagnosis is founded are derived, partly, from the statements of the patient (the *oral* examination, as I am in the habit of terming it); and partly, from the direct observation of the physician himself (the *physical* examination). Both methods are difficult to learn; and it is only after considerable practice and experience that you can hope to observe and note the facts correctly.

Let me urge you to use your utmost endeavours to correctly elicit and record the facts of the case. In these days of clinical and literary activity, one of the main lessons which the teacher should impress upon the student, is the *habit of careful, accurate, and truthful observation.* No one is a truly great clinical observer who is not scrupulously truthful and exact. Let me beg of you, then, from the very first to strive above all things to elicit and record the facts *as they are in nature*, and to be on your guard against seeing the facts in a false light, colouring them, and making them fit in to the supposed nature of the case. If there is one thing above all others which I desire to teach you,—and if I were to impress you with this one point only, and to teach you nothing else during the whole session, the course would not be altogether wasted—it is to have in every clinical observation, however trivial, the most scrupulous regard for truth.

The conclusion derived from the facts.—As I have already stated, due significance must be given to the different facts, and a logical conclusion deduced from them. Here, again, knowledge and experience are necessary to enable you to appreciate the relative importance of the different facts. Some facts are much more valuable than others. It occasionally happens that a single fact is itself distinctive; the presence of a diastolic aortic murmur, for example, indicates aortic regurgitation;[*] the presence of hooklets in the fluid drawn off from a cystic tumour proves that the cyst is an hydatid. Such facts as these, which are in themselves distinctive, are termed *pathognomonic.* But while such pathognomonic facts do occasionally occur, you must clearly understand that they are rare. The great majority of symptoms and physical signs are common to several diseased conditions. Pain is perhaps the most common symptom, and is seen in a vast number of different affections. Again, cough may be due to many different disorders. So, too, dulness on percussion over a portion of the chest, which is normally resonant, may result from various lesions.

It usually happens in every case that we elicit some facts which are accidental and unimportant. In a case of pneumonia in an adult, for example, the fact that there had been an attack of scarlet fever in childhood would probably be of no importance whatever. In a case of mitral disease, on the contrary, a history of scarlet fever, a few years previously, might be of considerable value, for scarlet fever in some cases is attended with endocarditis, which leads to valvular disease of the heart.

Speaking generally, the *facts observed by the physician* (objective symptoms and physical signs), inasmuch as they do not depend upon the mere statement of the patient, are of more importance than the symptoms (*i.e.* the subjective symptoms or sensations experienced by the patient). Due weight should, however, be given to the symptoms unless there is some obvious reason to the contrary. When the patient is manifestly exaggerating, when he is labouring under some mental derangement, or when there is a motive to deceive, the diagnosis should be almost exclusively based upon the physical signs. Women are more apt to exaggerate than men; but this tendency is seen in its fullest extent in the condition called hypochondriasis, in which the patient imagines that he is the victim of all sorts of dreadful complaints, magnifies the most trivial ailments in an extraordinary manner, and seriously believes that he is the subject of grave organic disease. In hospital practice it is no uncommon thing to meet with patients who feign disease. These 'malingerers,' or 'hospital birds,' as they are called, pass from one hospital to another, and keep a roof over their heads by their deceit. It often requires considerable acumen to detect them. Malingering is, as we all know, not uncommon amongst schoolboys. It is also frequently met with in soldiers, sailors, prisoners, the inhabitants of workhouses, and the like. In railway cases, too, we sometimes meet with gross exaggeration and shamming. We find persons who have been in a railway collision, but who have received little or no injury, taking to bed, laying up for weeks or months, and pretending to be seriously ill in order to exact heavy damages from the company. Hence it is that all railway cases are looked upon with more or less suspicion; a most unfortunate circumstance for those persons who are really hurt, for in consequence of this feeling of suspicion, which is attached to all railway cases, the genuine ones are often inadequately recompensed.

In other cases, on the contrary, patients who are the victims of serious organic disease, make light of their complaints. In phthisis, for example, a patient will daily tell you that he feels much better, when it is manifest to the most casual observer that he is rapidly getting worse; indeed, so frequent is this hopeful state of mind in pulmonary consumption, that a special name, the *spes phthisica*, has been given to it.

Young doctors whose experience has been limited to hospital practice, and who start perhaps with an exaggerated notion of their powers of physical diagnosis, are apt to disregard symptoms. I know this from actual experience. The following case, which I met with soon after commencing practice, is in point: A man presenting all the appearances of robust health, and who was obviously not exaggerating, consulted me on account of pain in the left chest and back. Not detecting anything abnormal by physical examination, I pooh-poohed his complaints, and gave it as my opinion that there was nothing seriously the matter with him; soon afterwards he died suddenly; and on making a *post-mortem* examination I found an aneurism of the descending thoracic aorta. It had ruptured into the left pleural cavity, causing instantaneous death.

But while anxious to impress you with the fact that due weight should always be given to the symptoms, unless there is some strong reason to the contrary, I must not lead you to suppose that grave symptoms are necessarily present in every serious case; indeed, it occasionally happens that patients die who have manifested no symptoms, and made no complaints. Absence of symptoms in the presence of serious organic disease is seen more frequently in chronic than acute affections. In this case for example (see specimen shown to the class), in which a small aneurism springing from the base of the aorta, just above the valves, has ruptured into the pericardial sac, there were no symptoms during life. The patient was a butcher, he died suddenly one day in the street. During life he had presented all the appearances of robust and vigorous health; and so far as could be ascertained from his friends, had never made any complaint.

Occasionally, but more rarely, we see the same thing in acute affections. The preparation, which I now show you, is a striking illustration of this fact: A girl,

[*] A diastolic murmur has been recorded in aortic aneurisms, independently of aortic incompetence; but it is so infinitely rare, that the statement in the text may be safely relied upon.

æt 17, who had previously enjoyed good health, but who had never menstruated, complained of uneasiness in the upper part of the abdomen, and of constipation. The tongue was slightly furred, the pulse a little quick, the bowels had not been relieved for a week, but there was nothing to direct attention to any serious disease within the chest. A dose of castor oil was prescribed. A few days after I was suddenly summoned to the case, and found the patient dead. She had passed a somewhat restless night, but had got up to breakfast as usual; had suddenly complained of feeling faint, and had fallen back dead. All the organs were healthy with the exception of the heart. The pericardium was distended with turbid fluid, and both surfaces,—the parietal and visceral layers of the sac—are, you will see, coated with recent lymph. The case was one of pericarditis; syncope was the cause of death. On inquiry I ascertained that she had waded in the sea a fortnight previously, and for some days afterwards had been a little hoarse. There was no history of rheumatism. So trivial were the symptoms in this severe and acute case, that the patient was able to go about her work, that of a baker's assistant, until two days previous to her death. The case is a very interesting one, being an example of a rare disease—*latent* pericarditis, which was apparently *idiopathic*.

I have now detailed to you the ordinary means by which we arrive at our diagnosis, viz., by the *method of deduction*. In some cases we employ another method, viz., the *method of exclusion or negation*. When, for example, the facts seem to point to several, say four, different affections without indicating any one of them in particular, we endeavour to find some symptom which negatives or contradicts, and so excludes one of the four; the same process is again, if possible, repeated, and so on, until three of the four are excluded, and one alone remains. This method of negation is of value in some difficult cases, but "it is a roundabout method" (*Da Costa*), and is not adapted for general use. It should only be employed when the deductive method seems to fail. It is, too, an uncertain method, for, in using it, we must be quite certain that we have excluded all the possible conditions except one. If, for example, in the case I have supposed, there should be five instead of four possible affections, and if we have omitted to think of and take into account the fifth, that one (the fifth) may be *the* affection, and our conclusion will of course be false.

In other cases, again, we have recourse to therapeutics in order to clear up the case (we make a *therapeutic diagnosis*). In a case of supposed abdominal tumour, for instance, if, after giving chloroform, we find that the tumour disappears, we at once conclude that it is not a tumour in the ordinary acceptation of the term, but a "phantom growth." Or again, suppose the symptoms and physical signs clearly point to the presence of an intra-thoracic tumour, but are insufficient to enable us to say whether it is an aneurism or a solid growth; if after giving full doses of iodide of potassium combined with absolute rest, we find a marked improvement in the case, we should (speaking generally) be justified in deciding in favour of aneurism, for the symptoms caused by aneurisms are, usually, materially benefited by this treatment, but those due to solid intra-thoracic growths, which in the great majority of cases are malignant lympho-sarcomata, are not.

Then again, in other cases, we have to fall back upon the *theory of probabilities*, *i.e.*, the numerical chances in favour of one or other of two conditions. Suppose, for example, that a female patient came to us complaining of swelling of the abdomen, and that on examination we found that the cause of this distension was a large cyst; the numerical chances would be very strongly in favour of an ovarian tumour; and unless there were some strong reason to the contrary, the fact should be allowed due weight. In the great majority of cases in which we followed the numerical chances and diagnosed an ovarian tumour, our conclusion would be correct. The following is a case in which it was wrong: A married woman, æt. 33, was admitted to the Newcastle-on-Tyne Infirmary, under my care, on June 20th, 1877, suffering from great distension of the abdomen. She stated that she had enjoyed excellent health until two years previously, when she began to suffer from pain in the abdomen just above the right groin, and noticed that the lower part of her belly was swollen. The swelling, which was at first about the size of an orange, gradually got larger, and rapidly increased in size after the birth of her last child, which took place on April 1st, 1876. Of late her general health had deteriorated, and she had lost flesh. She had been married for thirteen years, and had had nine children. She had not menstruated since her last pregnancy. She was pale, sallow, and somewhat emaciated. The *digestive*, *respiratory*, *circulatory*, *urinary*, *nervous*, and *integumentary* systems seemed natural. The abdomen was largely and uniformly distended; it measured 41 inches at the umbilicus. The skin was somewhat tense, and the veins in the anterior abdominal wall were slightly visible. The front and sides of the abdomen were dull on percussion. There was some resonance in the left hypochondrium. On palpation, the outlines of a large tumour extending from the pelvis below, to the lower margin of the right ribs above, could be distinctly defined, and in addition some free fluid in the cavity of the peritonæum was detected. Distinct and independent fluctuation was perceived in the large tumour. There was tenderness on palpation over the cyst. On vaginal examination the uterus was found to be of normal size; a round elastic tumour about the size of an orange was felt in Douglas's pouch. Owing to the great distension of the abdomen, the abdominal viscera were displaced upwards, but the size of the liver was not, so far as could be ascertained, increased. From these physical signs it was evident: (1) That the distension of the abdomen was due to the presence of a large cyst; (2) That there was some free fluid in the cavity of the peritonæum; (3) It was further concluded that the cyst was ovarian; this opinion being based upon relation of the cyst to surrounding parts, the very distinct history, which the patient, an intelligent woman, gave of its growing upwards from the lower part of the abdomen and upon the numerical chances of the case.

On June 23rd she was attacked with subacute peritonitis. There was pain over the greater part of the anterior abdominal wall; and very distinct friction could both be felt with the hand and heard with the ear over the same parts.

On July 6th the pain was easier; the abdomen had increased in size, and now measured 44½ inches.

About this time the patient was seen in consultation by my friend and colleague, Dr. Arnison, to whose care she was transferred on July 9th. She was then, as indeed she had been all along, very anxious to have the cyst removed. Dr. Arnison subsequently operated. On opening the abdomen it was at once evident that the tumour was an enormous hydatid. It extended from the liver above, deep down into the pelvis below. Several smaller cysts were attached to the larger one, and it was one of these which had been felt *per vaginam*. The patient unfortunately died from peritonitis, a few days after the operation, and the body was removed from hospital before a *post-mortem* examination could be obtained. The exact point of origin and connections of the hydatid were not ascertained.

In order to arrive at a full and exact diagnosis, we are in the habit of advancing by the following steps or stages:—

Step No. 1. In the *first* place we endeavour to *deter-*

*

mine the particular system and organ which is primarily affected. This is generally easy. Sometimes, as in typhus fever for example, we are unable to localise the lesion in any special part.

Step No. 2. Having determined the system and organ which are affected, we next endeavour to *ascertain the exact extent of the lesion, i.e.*, to make an exact anatomical diagnosis. We endeavour to make an exact anatomical diagnosis, *firstly*, by making a minute physical examination of the affected organ, in the manner which I shall describe to you when I come to speak of the physical examination of the different systems and organs in detail. *Secondly*, by observing the effects which the lesion has produced on the affected organ itself; on the other parts of the physiological system to which it belongs; and on the economy as a whole. In stenosis of the mitral valve, for instance, we try to gauge the extent of the lesion by observing:—the secondary alterations, which have resulted in the size and shape of the heart; the loudness of the pulmonary second sound (*i.e.*, the condition of the blood tension in the pulmonary artery); the amount of engorgement of the systemic venous circulation, and the consequences which result from it, the exact condition of the arterial system, etc. *Thirdly*, by observing the exact nature of the symptoms; in some affections, more especially in some diseases of the nervous system, we obtain very valuable information as to the exact position and extent of the lesion, by paying attention to this point.

Step No. 3. Having formed an opinion as to the organ affected, and the exact extent of the lesion, we next endeavour to determine the pathological process, which is at work; and in trying to make a *pathological diagnosis* we take the following points into account:—

1. *The particular organ and parts of that organ which are affected.*

As a matter of experience we know that certain organs or parts of organs are liable to be affected by certain pathological processes; consolidation of the apex of the lung, for example, is very generally tubercular; a solid tumour of the body of the uterus is in the great majority of cases a "fibroid;" a chronic lesion limited to the posterior columns of the spinal cord is usually the sclerotic lesion of locomotor ataxy; an irritative "coarse" lesion on the surface of the brain is in most cases syphilitic; paralysis of the extensor muscles of both forearms (double wrist drop) is almost invariably the result of lead poisoning; and so on.

2. *The character of the physical alteration produced by the lesion.*—This can only be determined in exceptional cases. In the case of the lungs, for instance, certain lesions give rise to dulness on percussion. If, then, we detect the presence of dulness we narrow the limits of the inquiry.

3. *The nature of the symptoms.*—Deep-seated pain in the back, for example, occurring in an adult, and not attended by any marked disturbance of the general health, would be very suggestive of an aneurism.

4. *The mode of commencement of the attack, and the course of the case, especially the acute or chronic nature of the affection.*—This is a most important aid in arriving at the pathological diagnosis. When, for example, we find consolidation over the base of the lung, and when we know that it is of recent origin (*i.e.* acute), we can definitely exclude solid intra-thoracic growths. So, too, in a typical case of permanent hemiplegia, if the onset were sudden, we should conclude, as the result of experience that the pathological process was in all probability either extravasation of blood into the brain substance (hæmorrhagic apoplexy), or plugging of a cerebral vessel.[5]

The *exact mode of onset* is also sometimes important. In a case of hemiplegia, if the paralysis followed an epileptic fit of the localised (Jacksonian) type, we should probably be correct in concluding that it (the hemiplegia) would be of temporary duration, and further, that the pathological process at the root of the mischief would in all probability be a localised "coarse" intra-cranial lesion (tumour or localised meningitis.)

When considered in conjunction with the exact anatomical diagnosis, the mode of onset is often quite conclusive. We know, for instance, that sudden paralysis of the lower extremities in a child, characterised by flaccidity, rapid atrophy of the muscles, and unattended by sensory paralysis, depends upon an acute inflammatory process in the anterior cornua of the spinal cord.

5. *The presence of associated diseased conditions.*—In the case of a doubtful intra-thoracic growth, the presence of tumours in other organs or parts of the body, would show that the intra-thoracic disease was a malignant growth. Soo, too, in chronic Bright's disease, the presence of a solid and uniform enlargement of the liver and spleen, would strongly point to the lesion being "waxy." Again, in a case of intra-cranial tumour, the presence of associated scrofulous disease of the glands, lungs, or joints, would indicate that the central lesion was of a similar pathological character.

6. *The age of the patient.*—Certain pathological processes are common at one period of life, but rare at others. In some cases this fact may help to decide the pathological diagnosis. Deep-seated pain in the back, for example, in a young subject, would probably be due to caries of the vertebræ (Pott's disease). Pain in the same situation, during active manhood, might result from the presence of an aneurism; in an old person, from malignant disease of the spine.[6]

In addition to the points I have already mentioned (1, 2, 3, 4, 5, and 6), the following circumstances are sometimes helpful in deciding the pathological diagnosis:—

7. *The occupation of the patient.*—A rapid attack of ill-developed pneumonia with fever, ending in death, *in a woolsorter* would suggest anthrax. Headache, convulsions, and double optic neuritis *in a white-lead-worker*, would suggest plumbism, in others (*i.e.*, persons who had not been exposed to the action of lead) the presence of an intra-cranial growth.

8. *The abode of the patient.*—A cystic tumour of the kidney, if it occurred in Iceland, would probably be diagnosed as an hydatid, for hydatid disease is very prevalent in that country; neuralgic affections occurring in places where ague is endemic, are very often due to the malarial poison; and so on.

Before concluding these remarks, it may perhaps be useful to point out the chief sources of error in arriving at a full and correct diagnosis. In the *first* place, then, a diagnosis may fail through *insufficiency of facts.* The facts may be actually wanting. In the earlier stages of a febrile attack, for instance, it may be impossible to come to a definite conclusion; under such circumstances we must be content to make a *provisional diagnosis*, and to wait for the appearance of additional facts. Again, the facts may be insufficient owing to the information supplied by the patient being defective. Some patients wilfully conceal facts; others cannot furnish the necessary facts owing to their being children, foreigners, speechless, comatose, or affected with some mental derangement. In such cases, we have to fall back upon the friends for many particulars, and if, as it may happen, there are no friends, we must rely on the physical examination alone. In cases of this descrip-

[5] I say a typical case, for in hysteria we sometimes meet with sudden hemiplegia (presenting certain peculiarities however) which may last for a long time.

[6] This does not of course imply that malignant disease of the vertebræ does not occur in young persons, or that old people do not suffer from aneurism or caries.

tion, the grounds for forming an accurate opinion may be insufficient. This explains the difficulty of diagnosing simple affections in lunatics.

In the *second place*, a diagnosis may fail through the incorrect or erroneous observation of facts. The patient may wilfully deceive you, or your own observation may be at fault.

Defective or incomplete observation on the part of the physician, is a fertile source of error, especially to young practitioners. In a case of dropsy, for instance, the urine is found to be albuminous, and it is an easy and common error to conclude that Bright's disease is the cause of the dropsy. In many of these cases more careful and complete examination will show that the albuminuria is simply the result of congestion of the kidney; and that it and the dropsy depend upon a mitral lesion. I have again and again met with such cases in practice. I must ask you then to remember that because you detect one lesion, it by no means follows that there is no other lesion present; owing to neglect of this precaution, complications and secondary affections are often mistaken for the primary disease.

You should, too, remember, that in the course of the case new facts are apt to appear which may cause you to modify or add to your diagnosis. One is very apt, after having thoroughly examined a case and formed an opinion, to stick to that opinion, and to see everything else which subsequently appears in the light of that opinion. Again, unless we occasionally thoroughly re-examine the case, we may fail to observe the new facts which are developed. Such omissions lead occasionally to unfortunate results. In a chronic case, for example, the friends may desire a consultation. The consultant thoroughly examines the case, and detects something which has escaped your notice, simply because you have not looked for it. Such mistakes are very vexatious. The consultant will probably form an erroneous opinion of your skill. If he is inclined to "score" and make much of his own powers of observation, you may possibly lose the confidence of your patient. And here let me say, that when called in as consultants,—while on the one hand it is your duty to state honestly and fearlessly the opinion you may form as to the nature of the case; on the other hand you must give due weight and consideration to the opinion of your professional brother, you must take care to state your opinion as pleasantly as possible, and to avoid bringing into relief any omissions you may have noticed, and never, on any account, attempt to magnify yourself or your own opinion at the expense of your colleague. Remember, then, both in hospital and private practice, to re-examine your cases, and to revise your opinions. You will, too, find it a useful practice, whenever a patient or his friends are anxious to have another opinion, to go thoroughly over the case a short time before the consultation comes off.

In the *third place*, though the facts are sufficient and have been correctly noted, you may fail to give them the proper weight, or may draw an illogical conclusion from them.

After having made your examination, and presumably come to a conclusion as to the nature of the case, you will probably be asked by the patient for your opinion. In some cases the request should be frankly complied with, in others it should not. If your opinion is favourable, and you take a hopeful view of the case, you should at once communicate that opinion to the patient. A favourable opinion, confidently expressed, is of itself sufficient to effect a cure in many cases; in a large proportion of cases it will produce a decidedly beneficial result. An unfavourable opinion should in most cases be communicated, sometimes quite candidly, at others in a more or less guarded or indirect manner. Much will depend upon the nature of the disease, and the mental temperament of the patient. In some cases it is only by impressing him with the serious nature of the case that you can induce him to submit to the treatment you advise and to take proper precautions. In other cases again, an unfavourable opinion will make a man wretched for life. The following is a case in point:—A gentleman of an extremely nervous disposition had for some years presented a well-marked mitral murmur. The lesion was a stationary one, and the medical attendant being well acquainted with the mental constitution of the patient, had deemed it prudent to withhold the information from the patient, guarding himself, however, against accidents by explaining to the patient's brother the exact nature of the case. The patient, when passing through Edinburgh on his way to the Highlands,—it is now many years ago,—felt a little out of sorts. He consulted a physician, who told him that he had heart disease. The poor man was thunderstruck; he at once gave up his trip, returned home in a state of great mental agitation, and passed a miserable existence for a long time afterwards.

Sometimes, as I have already told you, we are unable to decide what is the nature of the case. Now, it is seldom if ever advisable for a young doctor to tell a patient in so many words, "I don't know what is the matter with you." The laity do not understand the difficulties which in some cases surround the diagnosis. If you tell your patients that the case beats you, they will probably go somewhere else. In such cases much tact is sometimes required to satisfy the patient without committing yourself. If, however, you are asked by a professional man, say in consultation, for your opinion in a case of this description, you should always clearly state your difficulties and doubts. To pretend to knowledge which you do not possess, or to attempt to gloss over the obscurities of a case, is simply one form of quackery.

Finally, let me urge you to avoid hasty conclusions, to form your opinion slowly and maturely; but, once you have made up your mind as to the nature of the case and as to the treatment you should adopt, to stick to your opinion, and only to change it when you are satisfied that there is good reason for doing so. Firmness and decision are essential for great success in practice. On the contrary, there is nothing which is more injurious than indecision. The man who is constantly changing his opinion and his treatment, will never command the confidence and obedience of his patients. Now it is impossible to possess the right sort of self-confidence, to act with the right sort of firmness and decision, unless you feel yourself thoroughly up in your work. I hope that the Course of Lectures which we commence to-day, will enable you to some extent at least to attain that end.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Epidemiological Society of London.

(Continued from page 792.)

Hospitalism—Pyæmia—Septicæmia—Osteo-myelitis.

In the year 1843, our knowledge of hospital disease, as it was incident on traumatic cases, was not extensive. When, in last century, one died while under treatment for an injury which was not, in itself, of a dangerous character, it was perhaps said that "he had contracted a fever in the house, *which was a very common case; it might be from the foulness of the air in the house.*"[29]

[29] "London Journals for 1765 and 1777," reports of cases in the Middlesex Hospital, which was then in a miserable state from want of funds.

An old writer ascribed the frequent occurrence of pneumonia in traumatic cases to hypostasis, occasioned by long confinement in a recumbent position. Surgeons were only too familiar with tetanus, hospital gangrene, and erysipelas. Travers had written a work on "Constitutional Irritation," and James Arnott and Carsweli had well described and depicted phlebitis as a sequel to amputation. When, in 1843, I published the result of a practical enquiry, made at Guy's Hospital, into "*Certain of the Causes of Death after Injuries and Surgical Operations in London Hospitals*,"[30] I had before me the observation by Dr. Thomas Hodgkin, that he had noticed mottling of the kidneys in two patients who had died after the operation of lithotomy, "*and in others who had sunk after operations and injuries;*" and a remark by Mr. Key, that he had scarcely ever seen a fatal case of lithotomy in which there was not discovered organic disease of some of the abdominal viscera, and more especially of the kidneys. These facts very nearly representing the state of our knowledge upon the subject of blood poisoning in surgical cases 41 years ago—I showed in my paper, that out of 153 fatal traumatic cases in Guy's Hospital, death was proved to have taken place from inflammation of secreting surfaces or internal organs (including the kidneys, liver, and spleen) in 134. In the remaining 19, the patients died from these causes: tetanus, sloughing, hæmorrhage, suppuration, erysipelas, and total deficiency of reparative action in the wound. In one case the cause of death was not discovered. In the 134 cases in which the patients died of internal inflammations, there was marked disease of the kidneys, liver, or spleen, or of all those organs combined in 90. Upon these data, I insisted upon the necessity of invariably taking the precaution of examining the state of the liver and spleen, and of testing the urine for albumen in each patient before deciding upon the performance of any surgical operation, and of postponing such operation, if possible, while either of these organs appeared to be enlarged or the slightest trace of albumen was detectable in the urine. I think that I may unhesitatingly declare that the above precautions were not employed in hospitals when I recommended them, or until long afterwards. My researches received fair credit from Sir James Simpson;[31] but, in 41 years, they appear to have died of old age, surviving only in the writings of my friend Sir Joseph Fayrer. Side by side with that excellent authority I observed this class of diseases in the Calcutta Medical College Hospital for nearly fifteen years. As I have mentioned above, this hospital was built for the express purpose of relieving the native hospital of its medical cases, the surgeons of the latter institution perceiving clearly that cases of dysentery and fever necessarily infect a surgical hospital. The new building was accordingly named the "*Fever Hospital*." Had it been designated the "Surgical Hospital," and had it been strictly set apart for traumatic cases, the result might probably have been more favourable; but, unhappily, the old plan of massing surgical and medical cases together in a common atmosphere was again adopted here; the result was that the place became a hot-bed for hospitalism in its direst forms.

Writing in 1854, when he was in the habit of visiting the wards of the still new building in his capacity of Government Examiner in the college, Dr. Kenneth Mackinnon stated that wounds made in operating there were apt to take on an erysipelatous action, tending to sloughing, especially in the rains. Subsequently to this, during the fifteen years of my incumbency as senior medical officer of that hospital, our best care could not keep its surgical wards free from hospitalism in its worst forms—pyæmia, osteomyelitis and, latterly, in 1873, erysipelas. Once, in 1866, there was a transient outbreak of hospital gangrene, which ceased when we removed the traumatic cases to tents on the flat roof of the building. There were, however, few years, up to the time of my leaving, eight years ago, in which some of those operated upon did not succumb to gangrene. Full and most graphic accounts of the hospitalism of that very unfortunate building have been given by Sir Joseph Fayrer in his "Clinical and Pathological Observations in India."[32] Within my recollection the localities surrounding the Medical College and Native Hospital might have been regarded as vying with each other in presenting all the most hideous impurities which characterised Indian cities 30 years ago. The surgical and medical sick, cases of amputation and compound fracture, sloughing dysentery, and malignant cholera, occupied a common atmosphere. The natives treated there were poor, though not, for the most part, markedly scorbutic, but probably none were free from malarial cachexia. Although never swerving, practically, from their determination not to abandon this very showy building, the Government were very liberal in carrying out most of our recommendations for its improvement. The eye patients had been removed to another building previous to my incumbency. The obstetric patients have subsequently been placed in a hospital of their own. At our solicitation, the native buildings which closely invested the hospital were cleared away, and the neighbouring town sewers and our own drainage were improved. We shared the benefits of the new water supply. The latrines on the surgical side were removed from the body of the building to separate towers. The surgical wards were, as far as possible, shut off from the medical. A lavatory and a separate ward for the male cholera patients were provided. The female cholera patients lay with the other sick up to the time of my leaving. We set apart a large and airy apartment (our council room and library) as an operation ward. We diminished the number of beds in the surgical wards, and laid down impervious floors throughout the building which, as it now stands, has probably been made the best of; but I and its many able surgeons have not succeeded in convincing the Government that it can never, by any practicable means, be rendered a fit receptacle for the sick and wounded of a city, standing, as it does, upon an oozy basis of town filth, situated close to a huge mal-odorous public market, and with its beds lying in the course of the prevailing winds which blow stenches from end to end of every ward.

In reply to my enquiry as to how the surgical patients have fared during the last eight years, my friend, Mr. S. Bowen Partridge, informs me that of that period only 21 months, ending December, 1879, were spent by him in surgical charge. During that time there was no case in his wards of pyæmia, osteomyelitis, or hospital gangrene. They were "certainly freer from all forms of hospitalism than they had been, and their surgical operations were very fairly successful." During that time Mr. Partridge had 46 scrotal tumour cases, with a mortality of five (one from erysipelas, of which there were several cases). He had twenty lithotomy cases, with eighteen recoveries, one death (an old man who died from kidney mischief after the operation-wound had healed, and who was found to have a stone impacted in the ureter), and one who, having been recently operated on, was still in hospital when Mr. Partridge left. He used antiseptics very freely, and paid especial attention to the cleanliness of their instruments, and to this, in a great measure, he attributes the good result in the stone cases. He invariably dressed all large suppurating surfaces, such as scrotal tumour wounds, with carbolised

[30] "Guy's Hospital Reports," 1843, p. 78.
[31] "Obstetric Memoirs," vol. ii., p. 10, and "Twelfth Clinical Lecture on the Diseases of Women."

oil, and an abundant outer covering of clean cotton-wool, which he looks upon as a most valuable antiseptic air-filter.

The following extract from Mr. Cockerill's Surgical Report of the Madras General Hospital for 1882, forms a pleasant contrast to my sad recollections of the Calcutta Medical College Hospital.

"All the surgical wards are cool and airy, being freely swept by the sea-breeze; and to this, and to the fact that the windows and doors are always open, I attribute the almost entire absence of erysipelas and other 'Hospital Diseases.'"

Osteo-myelitis took a long course of prevalence in the wards of my surgical colleagues, making its appearance suddenly and ceasing unexpectedly. By my friends' kindness, I watched nearly every case. I regret that the following remarks did not appear while this form of disease was prevalent.

Can we, in amputation, find a covering of Periosteum for the divided end of the bone, without the adoption of any sub-periosteal method?

I first proposed the following plan in 1875:—

Some 38 years ago I dissected a stump which has, on many subsequent occasions, afforded me a good deal of interesting thought.

As a general rule, the soft parts, after amputation in the continuity of a bone, appear to be gifted with the power of healing kindly over the divided cancellated structure. When, in exceptional cases, this does not occur, the result is disintegrative suppuration, ending in necrosis, chiefly involving the cancelli of the divided bone.

This destructive form of inflammation has the still unexplained power of extending upwards to the cancelli of the bone beyond the next joint, as from humerus to scapula. I am not aware that, in any given outbreak of osteo-myelitis, we have any certain power of arresting the infection, still I think that there is a conservative expedient to which we might always have recourse, and which deserves trial, on physiological grounds, whenever osteo-myelitis prevails. Further, I am strongly disposed to believe that, although it appears to be a retrogressive measure, the following provision could be made, with great advantage, in the majority of amputations.

In the case to which I refer, amputation had been made at the upper third of the leg. The patient had probably survived the operation about a month. The parts were greatly wasted. Anteriorly, there was a deficiency of integument and the posterior flap was integumentary. The operator had not sawed off the sharp anterior edge of the tibia. This edge of bone was perfectly uncovered, but it was still living. Above, to the extent of about half-an-inch, and underneath to nearly the same distance, the soft parts had receded from the tibia, leaving an out-jutting right angle of denuded bone; still, although the soft parts had thus receded, or probably sloughed from its sharp edge, they had in no way deserted the tibia. Appearing to have considered that the flaps could not heal over a bony edge of such extreme sharpness, the soft parts had actively undertaken the task of removing this troublesome angle.

Above, in a semilunar line across the spine of the tibia, and below in a similar line crossing the cancelli and the cut edges of the bone, there extended along the margins of the remains of the anterior and posterior flap, fringes of granulations. This upper and lower row of granulations not only surrounded the exposed edge of bone, but had buried themselves in the osseous structure, and had grooved it so deeply as to render it evident that, had the patient lived a little longer, the two lines of granulations would have thrown off the angle of bone (closing upon it as the cutting edges of a pair of bone pliers would do), and would then, doubtless, have met one another and thus closed the stump. Place the knuckle of one bent index finger between the index and middle fingers of the other hand, then bring the joints of the two latter fingers together, and you will see the manner in which the two lines of granulations isolated the condemned angle of bone.

On most careful dissection, I found that the upper line or lip of bone-excavating granulation was a process into which the retracted edge of *periosteum* had expanded itself; and that the lower granulating line was, in a precisely similar manner, produced by the *fascia* of the integumental flap.

Above its upper granulating line, the *periosteum* was found quite healthy and firmly attached to the front of the tibia. Behind its line of granulations the *fascia*, now acting as periosteum, was equally closely adherent to the cancellated structure.

These two very analogous structures were thus found equally co-operating in a salutary work, which, naturally, as it appears to belong to the periosteum, could scarcely be expected from the fascia, unless upon a recognition of this interesting natural law.

When Aston Key first promulgated the doctrine that, in strumous arthritis, vascular granulation-like productions from the synovial membrane advance upon the articular cartilage, erode it in grooves, and so remove it, I paid close practical attention to the subject, and convinced myself, and (*pace* Mr. Bryant) have always remained satisfied of the truth of his observations, largely confirmed as they are by what we observe in the processes of chronic necrosis of bone shafts and caries. In this stump a process, perfectly analogous to that described by Key, was employed by nature for the removal of the offending bone.

My father, a naval surgeon, amputated at Trafalgar (he had sixteen amputations in that battle), and on many other occasions. He was an insatiable reader, and had a most extensive knowledge of the professional history of his service from the middle of last century.

I wrote my paper upon the "Causes of Death after Operations and Injuries in London Hospitals," in his presence. I knew all that he knew about amputation. He feared tetanus and that malignant ulcer, which attacked all wounds in the scorbutic (some of his experience of this terrible disease is given at p. 488, vol. iii., of "Trotter's Medicina Nautica"), but I am confident that he had never seen or heard of the condition of spreading bone inflammation which we now term osteo-myelitis. *In his time all flaps were exclusively integumentary.* I venture to think that the above facts, proving as they do that fascia can perform the part of periosteum, plead for the re-adoption of integumental flaps, especially during the prevalence of osteo-myelitis and septicæmia.

(*To be continued.*)

ON THE CALCULATING SLIDE RULE AS AN ASSISTANT TO THE MEDICAL OFFICER OF HEALTH IN MENSURATION AND STATISTICS.[1]

By GEORGE PADDOCK BATE, M.D.,
Medical Officer of Health for St. Matthew, Bethnal Green.

SLIDE rules are instruments of immense use for purposes of calculation; they are easily learned, and are not liable to get out of order. To one who has once worked with the slide rule, and acquired facility in its use, it is always a matter of astonishment that an instrument so rapid and accurate in its results should be so little known, as the drudgery of calculation is

[1] Read before the Society of Medical Officers of Health, May 16th.

saved, and the trouble and liability to error involved in figuring out long sums is avoided by the help of this instrument.

Slide rules are of various patterns, and I show upon the table specimens of several different kinds. All are constructed upon the same principle, though varying in detail and in manner of usage.

The slide rule in its simplest form is a logarithmic scale of double radius; each half reads from one to ten, and each division is subdivided into tenths and hundredths; a precisely similar scale slides in a grove below it, and the divisions of the sliding scale read against those of the rule itself. The fundamental principles of logarithmical arithmetic are that the multiplication of common numbers is performed by the addition of their logarithms, division by their subtraction and involution, and evolution by the multiplication and division of the logarithm by the index of the power or root required. The slide rule is merely a contrivance for facilitating this, and for avoiding the trouble of hunting out the logarithms of numbers from printed tables, and of turning the resulting logarithms back again into simple numbers. Ordinary addition and subtraction cannot be performed by the slide rule, as it simply multiplies and divides.

The ordinary slide rule is a very portable instrument, but its scale is so short and the divisions are so minute that considerable practice is required before it can be used so as to obtain accurate results. Moreover, it is very trying to the eyesight, for in each operation the *first* figure only is read, and the others have to be found by counting up so many tenths, hundredths, and thousandths.

The rule to which I wish to draw special attention this evening is the one which is the invention of Professor Fuller, of Belfast. In this the scale, instead of being straight, is wound in a spiral form upon a cylinder, and the reading is performed by indices instead of by slide against slide, which is an immense advantage. This spiral slide rule is equivalent to a straight slide rule 83 feet 4 inches in length. The divisions are thus much more open than in the short rule, and the results are more easily and accurately read.

In each operation the first *three* figures will be found engraved upon the rule; the third is counted up by the number of tenths, and the fourth has to be estimated by the eye as quarter, half, or three-quarters of a tenth; the results are then absolutely correct up to the fourth figure, while the fifth and sixth are only approximately so, but with practice great accuracy may be obtained.

All numbers and divisions are to be read decimally, so that, owing to our want of a decimal system, all measurements and quantities must be converted into decimals before they can be worked on the rule. In order to simplify this process as much as possible, a series of tables are engraved upon the body of the rule, giving the value in decimals of fractions of the various measurements of length and capacity, and also of money and time, together with some other very useful tables of values.

The rule consists of a cylinder (upon which is engraved the scale); this can be moved up and down upon and turned round a body or axis, which is held by a handle; fixed to the handle is an index, called the "fixed index;" two other indices (whose distance apart is the axial length of the complete spiral) are fixed to a telescopic tube which slides in and out of the body; these indices can thus be placed in any required position with regard to the cylinder, or to one another.

The rule will work with the greatest ease and certainty multiplications and divisions containing a series of factors, single and double proportion, ratio and interest; and by means of the upper scale, which it would be somewhat confusing to describe without the rule in hand, the powers and roots of numbers are within the capacity of the instrument.

It will be seen that the scale commences with 100 and ends with 999; the hundred is read either as one, or ten, or a hundred, or a thousand, as may be required; all the others follow in like manner, so that 999 may be either ·999, or 9·99, or 99·9, or the whole number; thus it is always necessary to know the value of a result for which there are certain simple rules laid down.

Multiplication A × B.—The cylinder is moved till the first factor is read at the scratch on the fixed index, the movable index is set to zero, the second factor is then brought to the same index by moving the cylinder, and the product is read at the fixed index, and so on with any number of factors, such as the height, length and breadth of a room.

The rule for the number of figures in the product is the algebraic sum of the number of figures in the factors, minus one for each factor brought to the upper movable index.

Division.—State the divisor and dividend as a fraction, thus—

$$\frac{600}{300} = x.$$

Set the fixed index to the numerator and the movable index to the denominator, then move the cylinder till the upper movable index is at zero, and the quotient will be found at the fixed index; the rule for the number of figures is the algebraic difference between the number of figures in the divisor and the dividend, plus one for each time the upper movable index is set to the denominator.

Mortality Rates and Percentages.—The ordinary method is to multiply the number of deaths by one thousand or one hundred, and divide by the population. I have here the President's report on the Vital Statistics of Kensington for the year 1881. Table I. gives the necessary data for calculating the rates, shown in Table II. In order to show the degree of accuracy with which the rule works, I give in each instance the actual result as calculated by ordinary arithmetic to three places of decimals.

1880. $\frac{2884 \times 1000}{161462} = 17{\cdot}862$ per thousand.
The true result is 17·861 „

1879. $\frac{2992 \times 1000}{158316} = 18{\cdot}898$ „
Should be 18·896 „

1878. $\frac{3120 \times 1000}{154305} = 20{\cdot}220$ „
Should be 20·219 „

1877. $\frac{2625 \times 1000}{151310} = 17{\cdot}349$ „
Should be 17·348 „

1876. $\frac{2896 \times 1000}{148338} = 19{\cdot}521$ „
Should be 19·522 „

Estimating Population is best done by logarithms for rapidly growing districts, and the estimate may be checked in the ordinary way by the birth-rate and by the number of inhabited houses; but by the slide rule it is very easy to estimate the number of persons existing at any particular age, upon the assumption that the ratio existing at the census enumeration remains undisturbed. For when either of the movable indices is at one number, and the fixed index is at the other, and the cylinder is turned into any other position, though the numbers at the indices will be different, *their ratio will remain constant.* Thus, if one

index be set to the Bethnal Green population, as enumerated in 1874 (120,104 persons), and the other to the number of children under five years of age (18,142), and the cylinder be now moved round, so as to bring the estimated population for each year to the upper index, the proportionate number of children may be read off at the fixed index year by year, until we arrive at the 1881 population as enumerated (126,961 persons), of whom 19,380 were children. Now reading the rule we find it gives at the fixed index 19,180, two hundred short of the true number; this is not the fault of the rule but of the method, the results of which can only be an approximation, and when we distribute the error over the ten years, it is very small, only 20 per annum.

Mensuration.—The cubic capacity of rooms having a rectangular form is calculated by the multiplication of the height, length, and breadth, and for this purpose it is easier to take all measurements by the decimal measuring rod. I have had constructed and use measuring rods divided into feet and tenths of feet instead of inches; but this is not absolutely necessary, as the printed table on the body of the rule gives the decimal value of fractions of a foot.

Circular Wards.—Several hospitals have been built lately with circular wards. The calculation of the cubic contents of such as these would be somewhat tedious, as the method given in books on mensuration is $3\frac{1}{7}$ times the square of the radius multiplied by the height. The decimal value of $3\frac{1}{7}$ is 3·1416, and a ward 52 feet in diameter by 16 feet in height would work out as follows:—$26 \times 26 \times 3{\cdot}1416 \times 16 =$ 33979 cubic feet. Calculated out in the ordinary way, this gives a decimal fraction over; but unless the original measurements are taken with extreme accuracy it is a superfluous refinement to carry the result to a fraction, so that the figures as given by the rule are quite sufficient.

With a little practice one finds the rule capable of working out many problems, and I should not now like to be without mine. Indeed, I often wonder how I got on before I heard of it, as I am a bad calculator.

It is almost needless to say that all problems must be correctly stated before they can be worked on the rule, for, though wonderfully accurate, it is only a machine, and of no more use to a person who cannot correctly state a rule-of-three sum than a pencil is to a child.

The manufacturer of the instrument is Mr. Stanley, of Great Turnstile, and his name is a sufficient guarantee for the accuracy with which it is made. To the kindness of Mr. Stanley I am indebted for the loan of the other slide rules I show upon the table.

Prohibition of Adulterated Butter and Cheese in New York.—The New York Legislature has just passed the Bill prohibiting the sale or manufacture of all adulterations of butter or cheese. The careful investigation carried on by the Committee brought out many curious and disagreeable facts. It was shown that the manufacture of oleo-margarine might be cleanly, and the articles used not unhealthy, but that in many cases this was not true. It also appeared that it was often difficult to detect the difference between butter and oleo-margarine, except by the use of chemicals, and that oleo-margarine was never sold under its name, but as real butter. It was, therefore, recommended that the manufacture and sale be absolutely prohibited, as all attempts to regulate the business have failed. The Bill embodying this recommendation has passed the Assembly and Senate, and is to take effect after July 1st.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

CASES OF ENTERIC FEVER.

(Reported by Dr. H. Lewis Jones and Mr. F. C. Cresswell.)

Case I.—*Enteric Fever—Parotid Bubo—Perforation of Intestine—Death.*

(Under the care of Dr. GEE.)

W. H., aged 32, a porter in Smithfield Market, was admitted Nov. 19th, 1883. He had been drinking heavily for six weeks, and for a fortnight had felt ill, with cough, headache, and diarrhœa.

His face was flushed, expression heavy and listless, tongue dry and brown, many rose spots on belly and chest. Next day he complained much of the state of his tongue, saying he felt choked by it. It was swollen, very dry and brown, his hands were tremulous, and at night he became delirious. This was the commencement of delirium tremens, which lasted for six days, November 20–26, although at night he slept fairly.

On Nov. 27th he was rational, recognised his friends and complained of pain at angles of jaw, where there was fulness and tenderness, especially on the right side.

Nov. 28th.—Very great swelling and tenderness in both parotid regions, with much pain in swallowing.

29th.—Parotids as yesterday.

30th.—Better; can swallow with less pain; the swellings also decreasing, no fluctuation can be felt in them.

Dec. 1st.—Doing well.

2nd.—Suddenly seized with pains in abdomen, and symptoms of perforation. He died early on the 3rd, the cause of death being perforation of the bowel, just above the ileocæcal valve.

The right parotid was examined, and pus was found in the interstices of the gland.

Case II.—*Enteric Fever—Suppuration around the Parotid Glands—Recovery.*

(Under the care of Dr. CHURCH.)

Florence T., aged 3, admitted in November, 1883, on the third day of her illness, with headache, vomiting, and abdominal pain. On the eighth day rose spots appeared, and her spleen was plainly palpable. Bowels loose. The temperature gradually fell from 104° on the eighth day to 100° on the thirteenth, but that evening it rose suddenly to 103°, and first the left, and afterwards the right parotid region rapidly swelled until she could scarcely open her mouth; the whole face also became swollen and red. Matter rapidly formed, and on the seventeenth day both abscesses burst into the external auditory meatus, the left again preceding its fellow by a few hours. A week later openings were made in front of the ears, and drainage tubes inserted. Convalescence proceeded favourably but slowly, and a small abscess formed on the scalp, fifty-five days after admission, which was opened and healed well.

Remarks.—In the first case the great dryness of the mouth and tongue is noticeable, and it was Dr. Gee's opinion that the affection of the parotid glands might be directly connected with that state of the mouth, by extension of inflammation along Steno's duct.

Similar tender swellings of the parotid glands occurred in a severe non-fatal case of chorea in Dr. Gee's wards

in August, 1883, accompanied by a very dry state of mouth and tongue, but without formation of pus.

Dr. Angel Money, in *Medical Times and Gazette*, Vol. I, for 1883, p. 180, reported a case of parotid bubo in typhoid fever, where great dryness of the mouth co-existed.

CASE III.—*Enteric Fever—Purpuric Spots—Intestinal Hæmorrhage—Death.*

(Under the care of Dr. CHURCH.)

John H., aged 10, admitted in December, 1883. Had been ill eight days, with pains in the abdomen. Bowels not moved for six days. Temperature 101·2°. Four days after admission (twelfth day of illness) several rose spots appeared, and on the following day he passed two loose motions containing blood.

On the seventeenth day of the attack he was much worse, his face pinched, mouth dry and full of foul stringy mucus. His evacuations were passed involuntarily. On the twenty-first day a large conglomeration of purpuric spots was found near the umbilicus, and several others were scattered over the abdomen.

Two days later he died, the purpuric spots having slightly increased.

Post-mortem.—The colon was found full of blood and fæcal matter. Death evidently resulted from hæmorrhage, but its source could not be found. The ulceration of small intestine was moderate.

CASE IV.—*Enteric Fever—Ecchymoses—Relapse—Recovery.*

(Under the care of Dr. GEE.)

G. P., aged 23, admitted Nov. 29th, 1883. He had been ill since Nov. 23rd with headache, vomiting, cough and diarrhœa. The temperature on admission was 104° F. On the 1st of December rose spots appeared on abdomen; he became delirious, and the delirium, which was violent at first, but afterwards became moderate, continued until the 14th of December.

On December 6th (fourteenth day of disease), ecchymoses appeared on both hips. These increased rapidly in size, and on the 7th were each the size of the palm of the hand, and there were two small fresh ecchymoses on the front of the abdomen, the size of a shilling. His condition on this day and the next was very grave, with low delirium, and plucking at the bed-clothes; but after that he gradually improved. No fresh ecchymoses made their appearance, and by Dec. 19th the large patches over the hips had almost gone.

There was a relapse from Dec. 23rd to Dec. 31st, with slight hæmorrhage from bowel on Dec. 31st and Jan. 1st, and on Feb. 1st he left the hospital quite well.

Remarks.—The four cases do not give much help to prognosis beyond this—that neither of the complications foretells a necessarily fatal result.

Dr. Murchison, in his "Treatise on Continued Fevers," 2nd Ed. p. 582, says that he has six times seen parotid bubo complicating enteric fever, and of these six cases five died.

Trousseau too regarded the appearance of parotid bubo as a most unfavourable symptom.

Dr. Murchison also says (Op. Cit. p. 515) that purpura-spots and vibices are met with in rare cases, several of which have recovered, and he also gives a reference to Trousseau which we have been unable to find, as it does not occur in the earlier edition from which the English version is translated.

ST. THOMAS'S HOSPITAL.—The Archbishop of Canterbury will distribute the prizes to the students, in the Governor's Hall, on Wednesday, July 19th, at 3 p.m.

Medical Times and Gazette.

SATURDAY, JUNE 28, 1884.

THE Medical Bill came on for second reading in the House of Commons rather unexpectedly on Tuesday afternoon. Mr. Mundella, who has charge of it there, by virtue of his position as Vice-President of the Committee of Council on Education, did not speak at any length of its provisions. He felt both that they are pretty well known, and that they would have to be fully examined in Committee. He gave a slight sketch of the history of the agitation, which has been carried on more or less actively and persistently for very many years, for medical reform; of the grounds on which that agitation was justified; and of the reforms which the present bill is intended to effect. Its main principles are, he stated, first, the reform of the Medical Council, by diminishing its numbers, strengthening its powers, and giving direct representation upon it to the profession at large; secondly, an approximation to uniformity of examination, by means of the establishment of Medical Boards to regulate the examinations, under the control of the Medical Council; and thirdly, the provision that no one should in the future be admitted to the Medical Register, unless he or she had proved, at the final examination, his or her competency to practise medicine, surgery, and midwifery. The Government have no wish to imitate the State examinations of Germany and other countries, but they desire to make the profession in Great Britain rank as a body among the very first in Europe, and they believe the provisions of this Bill will place them in that rank. But they do not aim, happily, we may add, at any ideal uniformity, or unnecessarily high standard; and while adhering to the main principles of the measure, they are not pledged pedantically to all its details. Finally, Mr. Mundella asked for a full and fair discussion of the details of the measure in Committee; and, if we have understood him rightly, spoke of questions of colonial and foreign titles, of penalties for misuser of title, of medical education, and of some other matters, as questions which admit of amendment. He himself, he said, approached the whole matter with feelings of the deepest respect and gratitude to the profession, and hoped the bill would settle all the questions involved in a way that would add to the dignity and honour of such a noble calling. Altogether it will be admitted that Mr. Mundella showed a full comprehension of the importance of the measure, and a readiness to entertain any proposed amendments of it in a conciliatory spirit.

SIR LYON PLAYFAIR, who said that he had not expected the bill would be reached so soon, and that he would so soon be called upon to speak on it, enlarged on the points referred to by Mr. Mundella; but he spoke also, at some length, of the importance of making the profession more attractive to eligible candidates, and of taking care to secure, if possible, that the universities of the United Kingdom shall take a larger part in the education of medical men. He gave statistics to prove that, from one cause or another, the number

of medical practitioners has not, since 1861, increased in proportion to the increase of the population of the United Kingdom, and the profession had not attracted a sufficient number of men; and he thinks, if wisely framed and wisely administered, the bill may increase the numbers of the profession; while, if unwisely framed and administered, it may have the contrary effect. He dwelt on the great value of a university education in turning out medical men of general culture as well as of professional knowledge; and pointed out that in the constitution of the new Medical Boards care is taken that this training, which exists largely in Scotland and Ireland, and is becoming more common in England, shall still be given to a large proportion of the profession. Whether or no the proposed proportions of the representatives of corporations on those boards is right, will be, he said, a fit subject of discussion when the bill is in Committee; but the essential principle is this, that a university preponderance on the boards will be fair as giving a definite bias to a liberal professional training as against cram by mere examination and examining bodies.

Colonel King-Harman thought there was too much of the principle of centralisation in the bill, and said that the corporations in Ireland complained that it aims to a very great extent at minimising the powers they had worthily exercised, and at confiscating their funds. He announced his intention of proposing some amendments with regard to this question, and hoped they would be carefully considered by the Vice-President of the Council. Two or three other members of the House spoke briefly on the bill, giving it a general approval; but seemed to think that the final examination provided by it for the minimum qualification to practise is to be in addition to the final examinations of the corporations, and this they of course objected to. Mr. Gray distrusts the centralising tendency the bill will have in Ireland, and holds that it will probably end in the destruction of the independence of the local corporations; and he maintains they do not deserve such a fate. He thinks also that the influence of the universities on the boards will be greater than it should be; and he regrets the probable extinction of the Apothecaries' Hall. Whether he intends proposing any amendments did not appear, for while he was speaking the hour arrived for closing the afternoon sitting, and the debate stood adjourned. The bill again came on for consideration yesterday (Thursday) afternoon, but too late for us to be able to record the result here.

Mr. S. Leighton, who is indefatigable in his efforts to protect the children in our elementary schools from over educational pressure, drew the attention of Mr. Mundella on Thursday se'nnight to the fact that a recent weekly return by the Registrar-General contains the following statement, appended by a medical man to his certificate of the cause of death of a young girl: "This the second death in my practice within a week, the cause of which was produced from pressure at a Board School." Mr. Mundella replied that the case was under investigation, and that therefore he would not at present venture to express any opinion upon the medical statement referred to. Mr. Mundella was further asked whether, in consideration of the grave fact that the Queen's Bench Division of the High Court of Justice had decided that the master of a public elementary school has no authority to impose upon the children the duty of studying at home, he would not any longer instruct the inspectors of those schools that a school marked "excellent" ought to provide "a regular system of home exercises?" The answer given to this question by the Vice-President of the Committee of Council on Education was hardly worthy of his position as a Government official. He could not see any reason, he said, to modify the instructions to the inspectors of the schools. All that had been decided by the judgment referred to was that it would be illegal to detain a child in school after hours, against the will of the parent, because the home lessons had not been prepared. But that need not prevent managers and teachers from providing a regular course of home lessons for the children in the higher standards. He admitted that, according to this legal decision, home lessons are not obligatory, and that consequently a child ought not to be punished for not learning them; but, said Mr. Mundella, if we are to believe the newspaper reports of his observations, "I do not think this will make any practical difference." The popular interpretation of this declaration will surely be that the Committee of Council on Education consider that the preparation of home lessons is necessary, and that a regular course of them will be provided for; care being only taken that children who do not learn them shall not be punished in a way already judged to be illegal. Mr. Mundella feels sure, no doubt, that school managers and teachers will invent various not illegal modes of making scholars and parents feel that such lessons had better be prepared; but is it judicious or expedient to provide so possibly fruitful a source of discord between the managers of schools and the parents of the children forced to attend them? We trow not. The evidence of the existence of over-pressure in elementary schools is increasing in bulk and force; and it is rapidly becoming more and more important that great and wise care be exercised in enforcing the code of instruction for such schools. "Knowledge grows, but wisdom lingers;" and the tone adopted by Mr. Mundella is likely to excite a formidable amount of popular irritation against the management of the system of instruction over which he presides.

Lord Rosebery has shown in many ways before now that he has an exceptionally open mind for one of his order, but he never showed it more strikingly than in his suggestion in the House of Lords the other day that artists, doctors and other workmen, should be admitted to seats in that gilded chamber. For our own part we have for years been in favour of the creation of medical life-peers, believing that it would be a boon both to the State and to the profession; to the former by bringing to its counsels the scientific knowledge and judgment which are nowadays so frequently called for; to the latter by opening to its picked members a new and higher sphere of usefulness,

without exposing them to the ordeal of an electioneering contest, and by rewarding them at the same time with a less common and less burdensome honour than a baronetcy. A successful doctor now, feeling an hereditary title in store for him, is driven in his own despite to amass money in support of the future dignity; while if he saw before him the alternative of a life peerage, he could follow his own inclinations and leave even his eldest son to take care of himself. Science ought not to be driven to buttress up the privileges of primogeniture.

The *Standard*, in its comments on Lord Rosebery's proposal, says that there can be "no doubt whatever that Parliament, as a whole, might be very considerably improved by the admission of men to the House of Lords who will not, and cannot be persuaded to, undergo the toil and trouble necessary to secure and to retain a seat in the House of Commons. If the men of culture and refinement who seem likely to be driven every day further and further from the House of Commons could find a place in the House of Lords, it would unquestionably be a great gain to the country. The presence of such men as Mr. Herbert Spencer, Professor Huxley, Sir William Gull, or Sir Frederick Leighton in any Assembly could not fail to strengthen its character, and give it a greater hold on the confidence of the nation." That is a surprising and pleasing admission on the part of the leading organ of the Conservative party.

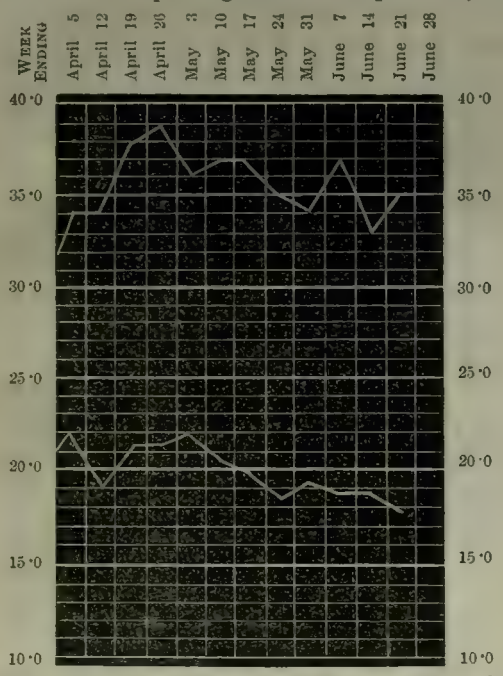
Mr. Gibson, who has made himself the spokesman of the aggrieved officers of the Indian Medical Department, gave notice in the House of Commons on Friday last, that he would call attention to that Service, and move a resolution that day four weeks, *i.e.*, on July 18th.

A most unwelcome guest, writes our Paris correspondent, has suddenly appeared at Toulon, under the form of cholera—whether Asiatic or sporadic is a question still at issue. Toulon, one of the most important naval stations of France, is also one of the filthiest cities in Europe. In the old town the state of the streets defies all description, and as there are no water-closets the refuse of private dwellings is simply poured into the streets, from which it is washed by the rain into the old port. A pretty similar state of things prevailed in Marseilles not very long ago, and the Phocean founders of the cities that stud the coast of Provence do not seem to have brought great notions of cleanliness from their home in Asia Minor. The port of Toulon constantly contains a powerful fleet, and the garrison of the place amounts to twenty-five thousand men. The seeds of disease when sown upon such a promising soil are apt to grow fertile. It has been supposed that a troopship, *La Sarthe* brought the infection from China. A death from cholera is said to have occurred on board, and the man's clothes were not burnt, according to sanitary prescriptions. Be this as it may, the first fatal case occurred on the 14th June (Saturday). A man died on board the *Montebello*. No further deaths occurred till the 19th, since when deaths have occurred daily, viz.: June 19th, 1 death; June 20th, 2 deaths from cholera; June 21st, 3 deaths from cholera; June 22nd, 13 deaths from cholera; June 23rd, 6 deaths from cholera. Captain Duroch, a retired naval officer, who lived in the country on his own estate, having been to the theatre at Toulon, died of cholera the next morning at his residence at Dardennes.

Drs. Brouardel and Proust were immediately sent to Toulon, with a Ministerial Commission. Drs. Straus and Roux, formerly members of the French Scientific Mission to Egypt during the late epidemic in that country, have also started for Toulon, to resume their scientific investigations. Great alarm is felt at Marseilles, which however is protected from contagion at present by the prevalence of the mistral (north wind). Six thousand persons are said to have left Toulon. The troops have been disseminated in various stations outside the city, and all proper sanitary precautions have been adopted. On Tuesday, at the Academy of Medicine, Dr. Fauvel distinctly stated it as his opinion, that the epidemic at Toulon was not Asiatic cholera. He founded his opinion upon the fact, that, instead of growing and spreading, as cholera would be sure to do, if it had once broken out in a city so unfavourably situated, the epidemic was actually losing ground. Drs. Brouardel and Proust, in a telegraphic report sent to the Minister of the Interior, state it as their distinct opinion, that the disease is only cholera *nostras*. The local physicians, however, maintain the opposite view. Proper measures for establishing special hospital services in all large French towns, in case of need, have already been taken. The new establishment known under the name of Hôpital des Mariniers, on the outskirts of Paris, has been devoted here to that purpose. Whatever may be the result of the present alarm, it must be hoped that the opportunity will be seized to use compulsory measures to reform the sanitary state of Toulon, which makes it a focus of infection, either in the case of true Asiatic cholera, or of cholera *nostras*. In the epidemic of 1865, 6,000 persons died at Toulon, out of a population of 70,000 souls, which, by adding the military garrison and the naval service, might be estimated at 110,000 in all. The Republican Government is bound in honour to suppress a standing nuisance, which is not only a permanent threat to the sanitary condition of France, but also to the health of other European nations.

The number of deaths in London last week was as many as 80 below the average, and the death-rate accordingly fell to 17·8 per 1,000, the lowest rate recorded for months. In only twelve of the twenty large English towns, and in only two of the eight large Scottish ones, was there a lower mortality. In both the zymotic and the respiratory class of diseases, the number of deaths exceeded the average—in the one case by 28 and in the other by eight—a fact probably due in some measure to the comparatively low temperature of the week. Of the zymotic class, measles and whooping-cough—the two in which a low temperature most sensibly affects the result—killed respectively 81 and 68 persons, or in the

one case 30, and in the other sixteen more than the average for the corresponding week in ten previous years.



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the first twelve weeks of the present quarter.

Diarrhœa and dysentery, on the other hand, were fatal to only 21 individuals, or 26 less than the average. Fifty-nine Londoners succumbed to small-pox in the week, though eighteen of the deaths occurred in the extra-urban hospitals of the Metropolitan Asylums Board. The zymotic death-rate for London was 3·5 per 1,000, and was exceeded in only three of the great English towns, viz., in Liverpool (4·8), Wolverhampton (5·3), and Norwich (4·0).

In recording the mortality statistics of the great towns, the Registrar General in his current weekly report has initiated a great improvement. Hitherto only the death-rate for the past week was given, but henceforward the death-rate in each of the three preceding weeks will be added, so that by a simple calculation the average for the month may be obtained. This evidently lessens the liability to error from causes interfering with the registration of deaths, which are much more likely to make themselves felt in a small population than in a large one. Thus, Blackburn, with some 100,000 inhabitants, records one week a death-rate of 26·4, the next week one of 17·0 In Bolton, with a similar population, the death-rate suddenly falls from 24·9 in one week to 16·3 in the next. In Cardiff, another town of about the same size, the death-rate of one week is 8·4 less than the preceding week; in Leicester there is a difference of 9·5. between two consecutive returns. It is obvious that for some cause or other in comparatively small populations a single week's mortality return gives no real information as to the health of the town, and the Registrar General has done very wisely in giving his readers the opportunity of striking an average.

The small-pox epidemic still continues to steadily advance. As many as 354 new cases were admitted into hospital last week, and there were on Saturday under treatment in the institutions of the Asylums Board 1,316 cases, or 78 more than on the previous Saturday. Unless there is a considerable increase in the numbers attacked within the next week or two, this total, which, has so far been steadily rising, ought now to begin as steady a fall. Three hundred and seventy-four cases have been discharged in the fortnight ending on Saturday, and 931 cases were then described as convalescent, so that there is some ground for hoping that the weekly number of discharges may soon exceed the weekly number of admissions. The strain on the Asylums Board has been excessive, but their efforts have been indefatigable and worthy of all praise.

A few weeks ago we had occasion, when dealing with the subject of school punishments, to speak at some length on the objections to that variety which takes the form of a box on the ears. It is unnecessary that we should recapitulate the anatomical and medical reasons for the view then taken. Public attention has lately been drawn to the subject by the action of a platelayer in withholding his little girl from school at the examination time, because the schoolmistress had boxed the child's ears three days before the examination, and the child had suffered from headache ever since. The school authorities summoned the father for the non-attendance of his child, and very naturally lost their case. Our sympathies are entirely with the aggrieved parent, although we are alive to the possibility that the headache may have been in some measure imaginary.

A distinct case of educational over-pressure, which may perhaps lead to the Government's sending an inspector to report *officiously* upon our medical schools, came before the Wandsworth magistrate last week. It was apparently a simple case of youthful frolic in which the traditional paint-pot played a large part; but the defence was less common-place. It was, in fact, stated on behalf of the offender that he was in training for a doctor, and had been upset by an unsuccessful examination, and he was accordingly remanded on bail. The plea is one which, perhaps with equal truth, might be put forward by a good many young men now in London; but the strange thing is, that these frolics on the part of medical students were much more common when there were few examinations to upset them. On the whole, the increase in the number and severity of examinations appears to have had a steadying effect.

During the past week there have been no less than three meetings in furtherance of a most deserving object: viz., the establishment of more convalescent homes for our sick poor. The meeting at the Mansion House had for its object mainly to support, and so to enlarge the sphere of action of, the Charity Organization Society. Those presided over by the Princess Christian and the Duke of Westminster related to the foundation of a new establishment and the support of the Metro-

politan Convalescent Institution, which has done good suit and service for well-nigh 45 years. All those who have much to do with the sick poor of London will welcome these efforts to provide additional and most valuable weapons wherewith to combat the evils that flesh is heir to in our great metropolis. People seem to be getting tired of subscribing to hospitals, judging from the state of impecuniosity in which most of them are representing themselves to be. Let us hope that the new excitement now offered them will stimulate the dilator fibres of their pockets.

The resignation of the whole honorary medical staff (with a single exception) of the North-West London Hospital, on Monday last, is but the final expression of a dissatisfaction with the existing management that had been growing rapidly of late. The last straw seems to have been the dismissal of one of their number on a charge in respect of which no explanation had been demanded from him. The charge, *on dit*, was of using unparliamentary language in the wards. We have nothing to urge on behalf of the officer in question, but surely the Committee would have exercised a wise discretion in addressing a friendly remonstrance to him instead of a curt dismissal. The action of the staff has, we are informed, perhaps been somewhat hastened by this dismissal, but had been for some time rendered inevitable by the unsatisfactory conduct of the affairs of the hospital by the Committee.

A meeting of the Committee of the new Association of Fellows of the College of Surgeons was held on Tuesday last, Mr. Pollock, President, in the chair. A letter was read from Mr. Bartleet, the Secretary of the old Association, denying the fact that that Association had ceased to exist after passing the resolution which was read by Mr. Wheelhouse at the meeting at the College in March last. It was thereupon resolved to write and invite the old Association to join the new one, and to incorporate the members of their committee with the present committee. A sub-committee was next appointed to draw up a general scheme of reform to be submitted to the committee, which, after being agreed upon, should be laid before a general meeting of the Association for discussion and adoption. A letter from the Secretary of the Members' Association, inviting the co-operation of the Fellows' Association, was then read. In reply, it was resolved that the Secretary should be informed of the nomination of a sub-committee to draw up a scheme of reform, upon the presentation of which a more definite reply to the letter would be given. Meanwhile, the Members Association was requested to give an outline of their own views of the reforms and changes which were thought desirable.

On Friday last Mr. Cowell removed from a patient in the Westminster Hospital a large fibrous tumour of the right ovary, weighing slightly over fourteen pounds. The incision was necessarily a large one, but there was only one small adhesion to omentum, and no difficulty whatever in the operation. Antiseptics were used and the broad pedicle was secured by thin silk ligatures, the cautery also being applied to the cut surface. The patient has so far (Tuesday) had no bad symptoms. The disease is a very rare one and it is proposed to publish a full account of the case.

A two-day conference was opened yesterday (Thursday), at the Health Exhibition, under the auspices of the Social Science Association. The programme for the first day included an introductory address by Mr. F. S. Powell, and a paper by Dr. J. H. Bridges, on the restrictions which should be enforced in the interests of the health of girls and women employed in factories and workshops. To-day Mr. G. W. Hastings, M.P., will deal with the notification of infectious diseases, and Mr. A. H. Brown, M.P., with legislation for Medical Officers of Health.

The composition of the various juries at the Health Exhibition has been made as far as possible international, for wherever it could be done representative foreign members have been attached. A glance at the names of the jurors shows that the executive have made excellent selections, and the awards should be considered authoritative and above suspicion. Difficult as all adjudication is, in this instance the difficulties are greatly enhanced by the hap-hazard way in which the articles have been thrown into various classes. The special "jury catalogue" before us is full of anomalies, examples of which are to be found in every page. Thus Messrs. Moir's canned foods are judged by a jury that has nothing to do with all other tinned meats. Methods and instruments for the analysis of foods are supposed all to be included in Class VII., but more than one important exhibit of this kind has strayed into a different department altogether. Among the blind the one-eyed is king, and an exhibit taken away from competitive exhibits may obtain an award by fortune, not by merit. Representations have been made to the Commission relative to the more glaring inconsistencies, and we trust that an immediate redistribution will be the result.

Two more of the appointments vacant by the death of Dr. James Stannus Hughes have now been filled up. Dr. Thomas Nedley, Physician to His Excellency the Lord Lieutenant, and Medical Officer to the Dublin Metropolitan Police, and to the Board of National Education in Ireland, has been appointed Surgeon to the Lord Lieutenant's household. Mr. Arthur Gerald Chance, Resident Surgeon to Jervis Street Hospital, Dublin, and Demonstrator of Anatomy in the Catholic University School of Medicine, has been chosen surgeon to Jervis Street Hospital, in succession to Dr. Hughes.

On Monday, June 23, Mr. Rawdon Macnamara was elected, without opposition, to fill the seat on the Council of the Royal College of Surgeons in Ireland, vacant through the resignation of Dr. Jacob, lately appointed Secretary to Council of the College. The *contretemps* whereby Mr. Macnamara lost his seat on the Council at the annual election on the first Monday in June is thus happily adjusted.

The election of a Joint Professor of Surgery at the School of the Royal College of Surgeons in Ireland will take place on Thursday, July 3rd. Among the candidates who will certainly be in the running for the Chair are Dr. Anthony H. Corley, Vice-President of the College; Dr. Edward Hamilton, an ex-President and Member of Council; and Dr. William Thomson, Examiner in the College.

The Royal Commission, writes our Belfast correspondent, which has lately been sitting in this town, investigating some matters in connection with the distribution of Scholarships and Exhibitions in the Queen's College, has brought to light some most interesting features in connection with the Medical School here. It has been seen that the Belfast Medical School has suffered most severely from the abolition of the Queen's University, the numbers in some of the class-rooms having fallen considerably below the half of the previous average. Nevertheless the School of Medicine in Belfast cannot be said in any way to have lost vigour. It consists, as most of our readers are already aware, of two very separate and distinct departments, the Queen's College with its medical professorships, and the Royal Hospital; these two departments are in no way connected or amalgamated and only in one instance does a teacher hold appointments in both places. The evidence taken by the Commission showed that though the number of the students had seriously fallen off in both the Royal Hospital and the class-rooms of the College professors, still the Hospital authorities, with the most commendable spirit, have during the last few years very materially improved the appliances and augmented the teaching staff of the institution, which now numbers fourteen members. It is also worth noticing that Belfast presents unusual facilities for the clinical teaching of special subjects, by means of the numerous special hospitals and dispensaries scattered through the town, the majority of which are greedily utilized by the earnest hard-working North of Ireland medical student. It is gratifying to find that though the recent University legislation has diminished for the present the number of students attending these institutions, their respective governing bodies and committees, with characteristic energy, have set about improving and perfecting their teaching arrangements, so that at no period in the history of the Medical School could its efficiency and teaching activity be for a moment compared with its present high standard of clinical education.

The important question of the *cause* of the temporary diminution in the numbers of medical students attending the College and various institutions was carefully examined by the Commissioners, and the evidence proves that it is mainly owing to the new requirements of the Royal University which has now replaced the old Queen's University. The late University enabled a student to take the M.D. degree within four years from his matriculation, whilst the requirements of the present licensing institution compel him to spend at least five years in professional study, the first year being devoted to art subjects, with a compulsory examination before beginning the medical course. This change, as might be expected, has told speedily upon the numbers of young men in a comparatively poor country, who otherwise would have been likely to have availed themselves of the boon which the older University held out to them. The Medical School may, however, be congratulated upon the fact that the extra year's training must enforce advantages upon the future graduates which to some extent will compensate them for their curtailed privileges. The following tabular evidence submitted to the Commissioners will give some idea of the facilities which Belfast at present affords to the students studying medicine at its school.

Hospitals in Belfast actually utilized for Clinical Teaching.

NAME.	No. of Beds.	Annual No. of Intern Patients.	Annual No. of Extern Patients.	Active Teaching Staff.
Belfast Royal Hospital— (Medical, Surgical, Ophthalmic, Gynæcological, and Fever)	180	2,000	10,564 (39,656 attendances)	4 Physicians. 4 Surgeons. 1 Gynæcologist. 1 Ophthalmic Surgeon. 2 Assistants. 1 Teacher of Pharmacy. 1 Teacher of Dentistry.
Hospital for Insane	510	683	...	1 Physician.
Belfast Children's Hospital	40	313	7,244 (14,319 attendances)	2 Physicians. 2 Surgeons.
Ulster Hospital for Women and Children	32	230	4,255 (7,568 attendances)	2 Physicians. 2 Surgeons. 1 Gynæcologist.
Extern Midwifery Dispensary — (in connection with Ulster Hospital)	...	...	300 Labour Cases	4 Physicians.
Belfast Ophthalmic Hospital	30	108	1,500 (6,000 attendances)	1 Surgeon.
Lying-in Hospital	15	250 Labour Cases	...	1 Physician.
Total ...	807	3,584	23,863 involving 67,543 attendances	24 (6 of the above 30 hold two appointments)

In addition to these institutions there are others which may be utilized for purposes of clinical instruction if at any time considered necessary. Thus there are the Union Hospital and Infirmary with 1,600 beds, the Throne Children's Hospital, the Samaritan Hospital, the Ulster Eye Hospital, Skin Hospital, Chest Dispensary, and Mater Infirmorum, with an aggregate annual number of intern patients of over 10,000. There are also six poor-law dispensaries, with about 25,000 cases, involving somewhere about 85,000 annual attendances.

These figures show that there is material enough for what we believe ultimately, and perhaps at no very distant date, will force itself upon the legislature, *i.e.* the establishment of a great Northern Irish University in the capital of Ulster, with its population of not far from 2,000,000. A University in the North of Ireland is especially necessary for the training of its future medical men, and the late Queen's University is acknowledged on all hands to have

produced some of the best men who ever entered the Army Medical Department and other branches of the public services. It may be supposed that the short period of its curriculum permitted men to obtain its M.D. degree without the prolonged course in art subjects which is insisted upon in older Universities; but it must be always remembered that the old graduates of the late University have ever held a high place in the struggle for professional existence in every corner of the globe. The rules which would apply to medical education in London, for example, could not be fairly applied in Ireland, and to insist upon the extra expense of a preliminary course in arts, which is often above the means of the men likely to become medical students, both as regards the amount of the class fees and the expense of one or two extra year's maintenance in a University town, is sufficient to seriously curtail the benefits which the present University offers to the inhabitants of Ulster. Future legislation arising out of the report of the present very able Commission will, doubtless, recognise the claims of Belfast to a University based on something like the broad non-sectarian lines of the late Queen's University, which has been a boon and a blessing to so many of the hard working men of the North of Ireland. The Commissioners, we hope and believe, must have left Belfast impressed very favourably with the care and labour bestowed upon the education of the men who are to be the future practitioners of medicine in the North of Ireland.

Professor Bèclard, Dean of the Faculty of Medicine of Paris, has issued a circular to the professors, students and officials of the Faculty, announcing that a list is open for the reception of the names of those who are desirous of joining the public subscription for a statue to the memory of the great chemist, J. B. Dumas.

The Editor of the *Gazette des Hôpitaux* states that the portion of the Sainte Anne Asylum, at Paris, assigned to Professor Ball for his clinic, is in a most disgraceful state. Beyond three separate cells, which, looking on to the street, expose their unfortunate inmates to jeers, insults, and all kinds of irritations on the part of the passers-by and the neighbours, nothing has been done to carry out the prescription of the law, which insists upon the separation of the violent from the quiet lunatics. All Professor Ball's demands for this state of things to be rectified have gone on unheeded; and in an establishment which should be a model, as it is intended for instruction, arrangements are obstinately adhered to which would not be tolerated in the most humble private asylums. All categories of lunatics are mixed up together during the day in a single court-yard, and accidents and fights frequently occur from the violent coming into collision with the quietly disposed. "It is impossible," writes the Editor, after a visit to this scene of violent confusion, "that this can go on, for it really is a scandal, and since the remonstrances of Professor Ball have produced no effect, the scientific Press must raise its voice in order to compel respect for the tutelary regulations, in the name of humanity and of the law, which on this point is most precise."

The Council of the St. Petersburg Military Medical Academy has determined upon the establishment of ten extraordinary professorships, to be chosen out of the forty *privat docenten* of the Academy. Three of these have already been appointed, viz.: Dr. Wassiljew, who will lecture, in Prof. Botkin's clinic, on the Bacteriology of Infectious Diseases; Dr. Danillo, in Prof. Mierszejewski's clinic, on Nervous Diseases; and Dr. Lawdowski, in Prof. Tarchanow's clinic, on Microphysiology.

We hear that the Medical Faculty of the University of Jena, which (in spite of the great name of Haeckel and one or two other brilliant exceptions) has for some time been in a comparatively languishing condition, has recently shown signs of renewed vitality. This re-animation has been brought about in a great measure by the infusion of new blood into the teaching body. Professor Rossbach has been summoned from Würzburg to occupy the chair of Laryngology, and Dr. Weber-Liel, for many years Privat-Docent at Berlin, has at last received a well-deserved *Ruf* to the professorship of Diseases of the Ear. The departments of ophthalmology, gynæcology, and mental diseases have also been entrusted to thoroughly competent hands, so that Jena now offers more facilities for the study of these various specialties than any other German University, with the single exception of Vienna. Whilst hardly, if at all, inferior to the latter place in its opportunities for medical study, Jena has the advantage of being much more accessible. At Jena, moreover, it is easier to practise the philosopher's ideal of "plain living and high thinking" than amidst the manifold attractions and *dis*tractions of the Imperial City. Situated as it is amidst lovely scenery, Jena is especially to be recommended as a place of residence during the summer months. Even those students—a decreasing number we are glad to think—to whom the language of Goethe (who, by the way, studied anatomy at Jena, under Loder) is unknown, may profitably spend some time there, as most of the professors speak English.

The Josephinum, as the medical school established in Vienna by the Emperor Joseph II., for educating surgeons for the Austrian army, was called, from its very first foundation suffered many vicissitudes, having been established and disestablished three separate times The present deficiency of surgeons in the Austrian army recently led the Minister of War, Count Bylandt-Rheidt, to appoint a committee to enquire into the advisability of once more re-establishing the old Joseph's Academy. The committee, which sat under the presidency of the War Minister, contained, besides several high military officials, General Stabsarzt Hoor, the Oberstabsärzte, Professor Podrazki, Wychodil, Chimani, R. and Carl Kraus, three professors of the medical faculty, viz., Professor Hofrath Langer, Professor Gustavus Braun (dean of the medical faculty) and Professor Hofrath Billroth, with Baron von Mundy and Dr. L. Wittelshöfer. Baron Mundy proposed that the Joseph's Academy should be re-established without debate. This proposal was not accepted, but at a second meeting of the committee, all the members except one agreed to advise its re-establishment, and a sub-committee was chosen to discuss the further details of

the scheme. The report of the sub-committee, which will shortly be presented, is looked forward to with interest in the Austrian capital.

At a recent meeting of the Society of Physicians of Vienna, Dr. Bergmeister showed a girl who was suffering from congenital dermoid growths on both eyes, which were situated symmetrically, partly on the cornea, and partly on the sclerotic. Such tumours, Dr. Bergmeister pointed out, consist of the tissue of the cutis, and sometimes contain fat; their growth is often arrested for a long time, but they usually develop rapidly at the age of puberty. This circumstance had determined the father of the child to come to Vienna for treatment. The disease in Bergmeister's case is associated with a peculiar complication, viz., facial asymmetry. The left corner of the mouth stands at a higher level than the right one, and there is a cicatrix extending from it to the left ear; the left side of the face is also less developed than the right. The association of dermoid tumours with warts in the præ-auricular region has been remarked by Arlt, and cases in which such dermoid tumours have occurred together with colobomata and other abnormalities have been published. Besides colobomata of the lids, hare-lip, clefts of the nose, and asymmetry of the hard palate, dermoid growths have also been found associated with colobomata of the eye-brows, circumstances which render it probable that these pathological abnormalities must have a common cause. Van Dugse has attempted to explain them by assuming that they are the result of a process which takes place *in utero*, the amniotic membrane uniting with prominent portions of the epidermis, as, for instance, the eye-ball. In the case above mentioned Dr. Bergmeister is inclined to regard the præ-auricular cicatrix on the left side of the face as a "fissura buccalis," which had become closed *in utero*.

There is a striking similarity in the histories of all great advances in operative surgery. A bold innovation is brought to a successful issue, and the name and fame of the venturesome operator is borne to the uttermost parts of the medical world, to which the ubiquitous *Centralblatt* may find its way. Equally bold, but less successful attempts are gradually heard of, and are sometimes published. The tide of opinion instantly turns, and the pioneer and his followers are roundly condemned for their unjustifiable and reckless experiments. Gradually, and with many ebbings and flowings of this same tide of fashion in opinion, the successful cases begin to accumulate, and the rationale of the operation, and the arguments for and against it, come to be weighed by the more responsible minds of the medical community. Finally, an authoritative acceptance of the proceeding is made by some great leader of surgery and the new operation takes its place, amid a flourish of journalistic paragraphs, in the recognised catalogue of surgical possibilities. The operation of extirpation of the kidney has lately been granted this honour at the hands of Professor Billroth, in an address recently delivered. The previous history of this operation is in some measure identical with the foregoing sketch. Fifteen years ago it was looked upon as a curiosity, if not exactly a monstrosity, of surgery, and at the present time no less than 250 cases are on record.

Dr. Billroth shows how absolutely untrustworthy is the record of successful, as compared with fatal cases, in determining the prognosis of any single case. Where the number of recorded cases is as yet trifling for statistical purposes, it must happen that a large number of the fatalities are due simply to the late stage of the disease at which the operation has been undertaken, and further, to the physiological imperfection of the opposite kidney. This after all is the chief consideration in these cases, since it has long ago been proved that a single kidney is sufficient of itself to fulfil adequately all the renal functions, and the certainty of the presence of a healthy kidney on the opposite side must rob the operation of much of its dangers, at any rate from the operator's point of view. We hope to present a complete abstract of Professor Billroth's address in an early number.

"The almost enthusiastic welcome" with which his remarks on gynæcological subjects in his Gulstonian Lectures were received, has emboldened Dr. Clifford Allbutt to a further attack on the abuse of specialism. The reproof and warning with which he prefaces the reprint of his lectures on Visceral Neuroses, just published by Messrs. Churchill, will be read with scarcely less approval than the original attack, and we make no apology for bodily transferring them to our pages. "London practice," says Dr. Allbutt, "is unhappily at present eaten up by specialism outspecialised. A smooth-tongued and audacious gentleman needs but six months' practice in the manipulation of some endoscope or other to become a dexterous specialist and a thriving tradesman. How is the public to judge between this man and those learned and capable observers who have found the infinite in the least of things, and who breathe into the study and teaching of the meanest of phenomena a spirit bred in the contemplation of the most lofty? For, indeed, the best men of the day are too lenient in this matter. A young lady told me but lately that a London physician of this strength—one who is chiefly known as a lung doctor, but yet one under whom I would gladly place myself or my friends for any malady—said to her that, having found her lungs to be healthy, he would name another physician who would care for her 'general health.' Now is this sort of thing, of which we hear every day, a tribute to an imbecile kind of etiquette, or is it an indulgent tolerance of something short of rectitude? In any case, if it continues to find encouragement the reputation of our London schools, so dear and precious to us all, must assuredly wane. The robust general practitioners who do possess a wide knowledge of their profession, have hitherto tolerated these manœuvres to please their patients; but they are getting tired of this fashion and contemptuous of its children. The specialist in his turn is beginning to ignore the general practitioner and to annex his patients, and thus science loses, practice loses, and the good fellowship of a great profession is dissolved." With regard to the last point our own experience leads us to believe that the general physician loses more than the general practitioner. People,

especially in the better classes, are getting into the habit of consulting a specialist in all local complaints, and they find the general practitioner more convenient and cheaper for those minor general ailments for which they would have once consulted a physician. If the ailments fail to yield, they find they can ask the general practitioner which specialist to go to with much less embarrassment than they could have asked the same question of a grand physician. The fact is, that general practitioners have been much more responsible for the undue growth of specialism than is generally believed. If, educated by such men as Dr. Allbutt, they could be induced to agree amongst themselves never to recommend any but honest and conscientious specialists, many of the "endoscopists" would soon be driven into other courses. Some day perhaps we may see a league of general practitioners for the regulation of specialism.

At the recent conference on cremation at the Health Exhibition, Sir Spencer Wells mentioned an important and interesting fact which tells strongly in favour of cremation in infectious cases, but which appears to have escaped mention in most of the reports of the discussion. Some persons who had died of scarlet fever were buried in a country graveyard; thirty years afterwards the graveyard was taken into a neighbouring garden, and the old graves were dug up. Scarlet fever forthwith broke out in the rectory and parish, and no other probable source of infection having been discovered, it is difficult to avoid the inference that the germs of scarlatinal infection can retain their vitality during close upon a third of a century.

THE NOTIFICATION OF INFECTIOUS DISEASES.

The assumptions on which the demand for the notification of infectious diseases is based are, from a theoretical point of view, such as admit of no dispute. They are simply these—that if the first sporadic cases were immediately made known to the sanitary authorities, and by the prompt removal or isolation, where practicable, of the first case, and, as they appear, of any that may have been already infected, the extension of the disease beyond the particular house were prevented, it would rarely assume the magnitude of an epidemic; while, at the same time, in the case of typhoid or diphtheria, opportunity would be afforded of discovering and remedying the sanitary defects to which such diseases owe their origin, or which are at any rate important factors in their development. Secondly, that a large proportion of every population are so housed that, though they are not in the legal sense "without proper lodging and accommodation," that is, not without the means of properly tending the patient himself, yet isolation is out of the question unless either the patient or his family be removed in time. Thirdly, that whatever seclusion may be practised in private families there are numerous establishments which cannot fail to become *foci* for the propagation of infectious disease unless prompt measures are undertaken, measures which the public are utterly incompetent to carry out, and medical men themselves are often little if at all more capable of directing. Such are laundries, tailors' and dressmakers' workshops, dairies, shops of all kinds, but especially those for the sale of food and clothing, factories, or places where numbers of workpeople are employed which are under the same roof with dwelling-houses where such disease exists, lodging-houses and schools both boarding and day. Instances of the spread of disease, often with disastrous consequences, by every one of these establishments could be quoted by the score, and it cannot be denied that in all, or nearly all, the results might have been averted by early information of the first outbreak of disease and the removal of the cause.

The opponents of notification take their stand on such ethical, economic and practical grounds as the following. They assert that in some, not all, towns where notification has been tried the results have not fulfilled the expectations of the promoters. Granted; but has it not been owing to defects in the administration of the Acts and the want of willing co-operation between the parties concerned? It is further contended that it is an undue interference with the liberty of the individual and the privacy of the home; but do we not already regulate the storage of explosives and inflammable matters in private houses for the protection of adjacent properties? A third objection is, that it might bring ruin on a tradesman if it were generally known that he had a case of small-pox in his house. This objection we are convinced rests on at least two fallacies—first, that notification is synonymous with publicity; and secondly, that it would always involve closure of the establishment. But both these assumptions are untrue. Where no opposition or obstruction is offered public officials are not in the habit of divulging matters communicated to them in their professional capacity; and if they should do so, all that they would have to say would be that there was no longer any danger, the proper measures having been taken either by the complete seclusion of the patient and his attendants from the business or by his removal when such seclusion was impossible. Further, we imagine that the ruin of a milkman, or washerwoman, or lodging-house keeper who was found to have been the cause of an epidemic would be far more complete than of one who was known to have taken, under official direction, the very best precautions to avert such a contingency; while in the extreme case of the obstinate refusal of the party to submit to the carrying out of the necessary measures and the consequent closure of the business, or as is the practice in some places the placarding of the house, would it not be far better that one family should be ruined than that many should perish by the death of the breadwinner, or suffer the loss of wife or child?

But the opposition is not confined to the laity; medical men themselves have been known to urge that the removal to hospital of a patient who could not be properly isolated has caused them considerable pecuniary loss! We would remind such practitioners that they exist for the good of the public and not the public for their enrichment. Every efficient vaccination and re-vaccination of a person above the rank of a pauper may be said to involve a possible or contingent pecuniary loss to the profession; and it is the glory of that profession that its members are every-

where the most active promoters of all that can tend to the prevention of disease, though their efforts too often meet with small thanks. A more plausible objection is the risk of professional discord between the family medical attendant and the medical officer of health when the latter is engaged in general practice. So long as men in private practice hold these appointments, and especially where the remuneration is so paltry as to attract only the junior and struggling, not to say inferior, members of the profession, the inducement to disparage and supersede the actual attendant will exist and may be yielded to by men deficient in a high sense of honour. The remedy however is obvious, viz., the appointment of medical officers of health either precluded from practice or engaged only as consultants, whose advice and assistance would in either case be willingly accepted or sought.

Notification may be voluntary or compulsory. Voluntary notification has been tried and found wanting, those cases in which it is most necessary being often just those in which it is withheld, private inconvenience and public danger generally going together. As to the party on whom the onus of notification should rest, there has been great diversity of opinion. Apart from all sentimental objections founded on the sanctity of the relations between the patient and his medical attendant, or the supposed indignity of subjecting the latter to compulsion under penalties for default, which by the way is not urged against the duty of giving certificates of the cause of death &c., we must maintain that on many grounds the medical man is the proper party. He alone can diagnose the disease aright, or be provided with the requisite forms or know exactly where, when, and how to give information. The objection that the knowledge on the part of householders that he will report will lead to the neglect to call in medical advice, has not been realised; but such a possibility is effectually met by making the householder equally responsible. That is, that when the doctor has informed the head of the house of the nature of the disease, he shall not only notify it himself, but provide the other with all the requisite information for a separate notification, and that persons who neglect to seek professional advice must find it out themselves or take the consequences of subsequent detection. If a man knows that concealment will involve the risk of a heavy punishment it will be indifferent whether the doctor reports or he does so himself, while self interest will induce him to seek a duly qualified attendant. On the other hand, where there is no compulsion and concealment may be practised with impunity, medical men and patients are sometimes tempted to hush up the unpleasant fact even to the extent of giving a false or equivocal certificate of the cause of death. Space forbids our at present entering on the question of hospital accommodation in places where notification is enforced; we can only observe that though hospitals are necessary for securing the fullest benefit, yet, since *removal* of the patient is not the only measure calculated to check the spread of infection, some good may be effected even without such provision; and as regards the errors of diagnosis familiar to the officers of all fever and small-pox hospitals, the painful consequences of sending a patient thither by mistake and the anxiety to those around caused by such erroneous diagnosis when the sick person remains at home would be prevented by the calling in of a medical officer of health who has made the recognition of these diseases an object of special study.

SANITARY YEARNINGS.

In his eloquent oration of last week, Sir James Paget was undeniably optimistic, as no doubt was quite proper and becoming in one who spoke as a teacher. If we were to put our pessimists into the pulpit, conversions would be few. Still, be the preacher's faith as glowing and his accents as encouraging as they may, there are many of us who, in this matter of national health, are not to be drawn for more than a moment out of those shades of hopelessness in which we habitually move. We can admire to the full the tough, pliant and elastic health which Sir James Paget depicts; we can cherish aspirations and yearnings after it, but when we are told that it is within our reach, we reply for ourselves and tens of thousands of our countrymen, that to hope for it and strive for it were fruitless. We are tempted to say to the "pattern healthy man" as the young lady of the last century was taught to say to her *chaperone*—and we can say it with less evident hypocrisy—"Madam, I can admire, but cannot imitate your virtues." A man need not be a hopeless hypochondriac to hold this belief, or rather want of belief. He has only to go into the slums of the East End and watch the puny, narrow-chested, and hopelessly diseased race into which the once stalwart English people have dwindled; or into the *salons* of the West End and review the wan matrons and be-dentelured *debutantes*, to be infallibly stripped of the last shred of the enthusiasm which Sir James Paget's eloquent words have woven around him. Then if he looks at his friends, his contemporaries, the men who are doing some of the best work in the world, he is quite inclined to think that the *British Medical Journal* has blundered nearer the truth than Sir James Paget, and that science and art *are* after all, "dependent upon invalids." It is impossible, in short, for him to help feeling that all our efforts in the cause of health are but as the toiling at the pumps of an exhausted crew, while the ship is leaking two gallons for every one that they can raise. It is an entirely new experiment in nature, evolving a healthy nation out of an unhealthy one. If they had had good material to start with, sanitarians, with all the manifold aids that science now gives them, and with some yet to be wrung from the State, might have hoped to make something out of this English nation; but the attempt is hopeless unless we come to breeding Englishmen as we do stock, and condemn everyone who has not a good health pedigree and a well-formed chest to perpetual celibacy. And even that experiment may fail, as stock-breeders have found out to their dismay. Still, as, to revert to our simile, we are on the ship and have got to make the best of it, it would be insane to sit down in despair because we cannot hope to make it watertight.

No one, surely, will deny the immense gain to us in health, money and happiness which would be involved in the limitation of the ravages of zymotic diseases. It is true, as Mr. Longstaff recently pointed out, that their entire abolition would not lower the general annual death-rate of England by more than three per 1,000, and that figure would include the whole mortality from diarrhœa, which cannot quite be regarded as a zymotic disease, in the sense that it is as likely to prove as amenable to sanitary measures as other diseases of the class. The ills, again, that spring from immorality and intemperance may, no doubt, be greatly curtailed by science and good sense working in alliance with the State, and other agencies. Blindness, too, a deviation from health which costs the individual much more prolonged and greater misery, and the State much more serious loss, than almost any single disease, and to which we are surprised that Sir James Paget did not refer, might be diminished to the extent of one-third, were the simple directions recently issued by the Ophthalmological Society faithfully carried out. Still there will always remain whole categories of diseases beyond the reach of sanitary science. The creed of the cold bath may do something to lessen the liability to bronchitis and the many diseases that spring from chill, but they will doubtless still continue, in spite of all ablutions, to furnish an immense contingent to the annual array of diseases and deaths. The same may be said of gout and rheumatic fever. In fact, anyone who will take the trouble to peruse Table 29 in the Registrar-General's Annual Report, just published, will see at a glance how many thousands of deaths—and by calculation how many millions of illnesses—from actual disease must always lie beyond the realm of preventive science—*opprobria sanitationis*.

There is yet another point to be considered. In spite of all our efforts and yearnings after health—nay, perhaps in one respect in consequence of them—there is a class of disease which, during the last generation, has advanced by giant strides—diseases of the nervous system. In 1859 the deaths attributed to this cause numbered 26,871; in 1882 the number had risen to 46,806. In the same period the suicides, which might very well be put under the same category, mounted from 1,248 to 1,965. Now, granting that many of the deaths included under nervous diseases may have been due to senile degeneration of vessels, and are therefore admittedly beyond the scope of preventive medicine, and that another large contingent may have had their remote origin in syphilis and drink, there still remains a melancholy residue which no preventive science is likely to touch, and there also remains a notable increase during recent years, much of which on no hypothesis of more accurate certification can be explained away. What can science do for these cases and for this increase—which, according to all appearances, is likely to be more and more marked as the years go on—except by demands for celibacy, which neither the State will endorse nor the individual obey? Why the very conditions of civilisation, which alone make the advent of a sanitary *régime* possible, are in themselves adding yearly more to the number of nervous deaths and nervous sufferers at one end, than science by its best efforts can cut off at the other. To get sanitary rules appreciated and carried out, you must educate; you educate, and immediately find yourselves feeding the lunatic asylums. Then, side by side with fatal nervous disease there is the whole class of neuroses, the possession of any one of which, even in its mildest form, at once disqualifies a man from entry into Sir James Paget's pattern class. The immense increase of this class of diseases within the present century is recognised as a truism, and we think that even the most enthusiastic sanitarian would not be seriously offended if some of the increase were with all imaginable politeness laid at his door. We do not give vent to this assumption in any reactionary sense, or with a view of detracting from the noble gifts of sanitary science; but sanitary science must, like other things, be content to have the defects of its qualities, and this is one of them. The very anxiety for health, which Sir James Paget and the sanitarians inculcate, is an anxiety that breeds hypochondriacs, and tends to that extent at any rate to defeat its own object. Everyone must admit that the highest form of health is unconscious health, just as the highest form of beauty is unconscious beauty, and the highest form of moral excellence is unconscious moral excellence. The typical healthy man is not aware of his health; he does not think about it at all. But the sanitarian would treat him as many a man treats unconscious beauty; he would forthwith proceed to render him not unconscious. In short, the lessons of the sanitarians are, for most of us, making individual health like the "blue flower" of Novalis—a thing to be sought throughout life with infinite yearnings, but never, alas, to be secured.

CLINICAL PAPERS.

XIII. — Some Moot Points in Connection with Diphtheria.

Dr. Parsons' paper on the ætiology of diphtheria, read at the last meeting of the Epidemiological Society, an abstract of which recently appeared in these columns, suggests several interesting and important points for enquiry, such as the frequency of mild and unrecognised forms of the disease, its propagation by direct personal intercourse and the relation, if any, in which it stands to scarlatina. Though the name is of recent introduction, the disease is probably as old as any of those which are connected with insanitary surroundings of human dwellings. In the 16th and 17th centuries the Spanish and Italian physicians described malignant and fatal anginæ, but they, as well as their contemporaries in other countries, failed, probably from the paucity of *post-mortem* examinations in those days, to distinguish between the ordinary catarrhal inflammations of the pharynx and adjacent parts and such as were symptomatic of specific disease. In 1740, the nature of the pseudo-membranous exudation was pointed out by Ghisi, but the treatise on croup by Francis Home, which appeared soon after, by diverting attention to certain symptoms common to all inflammatory affections of the larynx, put a check to further progress in the differentiation of these affections for full half a century. To Bretonneau, who began a course

of careful observations in 1821, we owe the first clear recognition of diphtheria, as a disease distinguished alike from all non-specific inflammations and from scarlatina by certain local anatomical lesions and by subsequent nervous phenomena perfectly characteristic. His views slowly gained acceptance in this country; but the spell of Home's teaching on croup on the one hand, and the importance attached by Bretonneau to the "false membrane" in diphtheria on the other, have exerted such a fascination on men's minds, that it is only now beginning to be understood that while the so-called true or membranous croup is simply laryngeal diphtheria, diphtheria may exist with only the most imperfect formation of a membrane. The term "croup" is equivocal, having reference simply to the peculiar alteration of the inspiratory or vocal sounds and cough consequent on laryngeal affection of almost any kind. It may mean a mere catarrhal laryngitis; or a true spasm of the laryngeal muscles, *laryngismus stridulus*, arresting during its continuance both expiration and inspiration; or it may be laryngeal diphtheria. In the last named, so long as the glottis is not occluded by membrane, inspiration only is interfered with, the muscles of the glottis being paralysed and not spasmodically contracted: the peculiar hissing inspiration is identical with that produced by section of the laryngeal nerves in animals or artificial inspiration effected by drawing air from below through the flaccid glottis of the dead body, being produced in all three cases alike by forcible inspiration through a glottis collapsed by reason of its entire loss of muscular tonicity. It is therefore much to be desired that the term croup were banished from our nosology.

It is impossible to draw any valid distinction between membranous croup and laryngeal diphtheria, because none such exists. Diphtheria may originate in any part of the pharyngeal, nasal, or laryngeal tract and extend to any other, theoretically at least, for though the laryngeal affection rarely if ever does so extend, it is simply because for anatomical reasons any serious amount of such diphtheria is fatal before it has time to spread, unless it end in speedy recovery, in which case it of course does not go beyond its original seat. But why should we persist in restricting the term diphtheria to those cases in which the fibrinous exudation is conspicuous and highly developed? We do not act thus with other specific diseases. We are all familiar with cases of scarlatina in which there is no rash and the nature of which is not recognised until symptoms of kidney mischief, of dropsy or uræmia, manifest themselves, or the nature of the first cases which perhaps recovered without any sequelæ is disclosed by their having given rise by infection to others of typical and unmistakable scarlatina. As Dr. Parsons remarked, whenever scarlatina is epidemic there are to be seen numbers of persons with flannels round their necks who do not suspect that they have anything more than a common sore throat the result of a "cold." And so it is with diphtheria, of which the membrane is but a fully developed stage of the exudation which, like the rash of scarlatina, is a symptom, not the essence of the disease—a symptom which may exist in any degree or be so imperfectly manifested as to escape recognition altogether

This imperfect development is indeed more likely to occur in diphtheria, since it is not so highly differentiated, not so specialised a disease as scarlatina. It is essentially a filth disease, and, as is probably the case with enteric fever, may be generated *de novo* though not *de nihilo*. When once called into existence, however, it is propagated by ordinary infection, whether through the vehicles of air, or water, or by personal contact, or by fomites. The same wide variation in its characters attaches to enteric fever which may be marked merely by looseness of the bowels, weakness and malaise. Indeed it may be said that these diseases vary in more than degree, and pass by insensible gradations into non-specific affections of the pharynx and intestine respectively. As to the relation between diphtheria and scarlatina it is difficult to believe that any true connection exists.

Dr. Parsons appears to have reposed too much on the registered causes of death when he spoke of some members of a family suffering from scarlatina and others from diphtheria, and of the two diseases co-existing or passing into one another. It is much simpler to believe that all such alleged instances are merely errors of diagnosis. That diphtheria may recur is undeniable, and that it and scarlatina are not mutually protective is shown by several cases recorded by Dr. Parsons in which diphtheria attacked persons who had suffered from undoubted scarlatina a few months previously.[1]

The meteorological origination of diphtheria maintained by Dr. C. Kelly and others can hardly be said to rest on any sufficient foundations. The alleged cases may have been simple catarrhal laryngitis, but more probably were due, if not to infection, to the insanitary condition of the villages in which they occurred, whether these consist in sewage pollution of soil and water, as in the Old World, or in the swampy ground reeking with rotten vegetable debris of an American backwoods settlement. Diphtheria is essentially a septic, or if one prefer it a pythogenic, disease, and all cases of sore throat due manifestly or presumably to insanitary surroundings and communicable or attacking several members of a family are, in fact, diphtheritic, although the typical false membrane may not be capable of being seen and handled. These are not unfrequently followed by the characteristic nervous phenomena, but the absence of such sequela no more disproves their specific nature than does the absence of dropsy that of mild cases of scarlatina. N.

Medico-Psychological Association. — The Annual General Meeting will be held at the Royal College of Physicians, Pall Mall, London, on Wednesday, the 23rd of July, 1884, under the presidency of Dr. H. Rayner. Meeting of Council at 10.30 a.m. A general meeting will be held at 11 a.m., for the election of officers, and other business. There will be an afternoon meeting at 2 p.m., the programme of which includes an address by the President, and a paper by Dr. Newth, "On the value of Electricity in the Treatment of Insanity." The Association Dinner will take place at "The Ship," Greenwich, at 7 p.m. Members wishing to attend are requested to communicate their intention to the Treasurer, Dr. Paul, The Terrace, Camberwell.

---

[1] Another point of distinction is, that the albuminuria of diphtheria, though it may lead to uræmia, is not, like that of scarlatina, accompanied by dropsy, while the paralyses of diphtheria are unknown in the other disease.

REVIEWS AND NOTICES OF BOOKS.

A Manual of Physiology; by GERALD F. YEO, M.D., Dub., F.R.C.S., pp. 632. London: J. and A. Churchill.—The author of this manual states in his preface that his book was "written at the desire on the part of the publishers that a new elementary treatise on Physiology should be added to the series of admirable students' manuals which they had previously issued." The writer has endeavoured to "avoid theories which have not borne the test of time, and such details of methods as are unnecessary for junior students." His experience as a teacher and as an examiner has led him to lay stress on the points which are hard to grasp and are commonly misunderstood, and he has directed attention more to those subjects which have a practical medical or surgical application than to those relating to abstract physiological subjects. We think the book before us a very good example of what an elementary physiology should be, and we have no hesitation in recommending it to students of medicine. It very fairly represents the physiological substratum, which every student should have at his fingers' ends, and the explanation of several difficult points is good beyond the average, notably the chapters on circulation and respiration. The author leads his readers through a general discussion of biological principles and elementary chemistry, contained in the first four chapters, entitled (1) The general view of the structural characters of animal organisms, (2) The chemical basis of the body, (3) The vital characters of organisms, to the subjects of physiology proper. Knowing from our own experience how ignorant the average student is of the most rudimentary principles of biology or chemistry, we think that this method is excellent; and the manner in which these difficult subjects are handled in these chapters is distinctly good. In the chemical chapter there is just one clerical error, viz., "kreatinin is a dehydrated form of kreatin which is a normal constituent of urine." It should be, *and* is a normal, &c. We think that in discussing the coagulation of the blood, while such prominence is given to the views of Schmidt, equal prominence should be accorded to the more modern ideas of Hammarsten. It is by no means settled that three fibrin factors are necessary; indeed, the probabilities are the opposite way. Even in an elementary book it is not always good to mention only one side of a controversial point. It is scarcely correct to say that the vagus endings in the heart are paralysed by atropin. The sections on muscle and nerve physiology are good. We notice an error on page 517. It is stated that "section of one side of the cord is followed by loss of sensation on the same side (it should be on the *opposite* side) with increased sensitiveness and loss of motion (recovering slowly) on the side opposite to the injury." This should have been written, on the *same* side as the injury. The illustrations throughout the book are good. Many of them are taken from Cadiat, and it is really a pleasure to meet with a fresh set of illustrations, for the old blocks have been copied and re-copied into different books, until one is tired of seeing them. We have pleasure in recommending this book, as a most excellent manual, being what it pretends to be—elementary, and yet containing all that is really of importance to the student of medicine. It is difficult to devise an original method of treating such a well worn subject as physiology, but the present volume undoubtedly has originality in its method. We think the author treats his subject in the best manner possible when he combines microscopical anatomy intimately with the discussion of strict physiology.

Bright's Disease; by HENRY B. MILLARD. New York: W. Wood & Co., 1884.—After the usual chapters on the anatomy of the kidney in health and the characters of the normal urine, the author discusses the various methods of testing for albumen, and the significance of the different kinds of casts that may be found. He then deals with the different forms of nephritis, acute and chronic parenchymatous, or, as he calls it, croupous nephritis, being first dealt with. Chronic interstitial nephritis comes in for the chief share of attention, as is only right, considering its relative frequency to the other forms. As to what he barbarously calls its general causology, he places "catching cold" in the first place, and amongst other causes he recognises the influence of malaria, of syphilis, of heredity, of gout, of lead poisoning, of cystitis, and of heart disease, but he does not admit that alcoholic excesses have any liability to produce this affection. The author does not commit himself to any very positive opinion as to the cause of the hypertrophy of the left ventricle, though he does not accept the explanations put forward by Gull and Sutton, or that suggested by Dickinson; he says that undoubtedly in the great majority of cases the cause of the cardiac hypertrophy is the renal change, but he leaves out of consideration altogether the general state of the arterial system. As to treatment, he speaks of curing cases of interstitial nephritis in the early stages in a much more hopeful and positive way than we, in this country, are accustomed to, and we cannot help feeling that the diagnosis of this pre-interstitial stage is a matter of greater difficulty than he thinks. The book is well got up in every way.

Corpulence and its Treatment on Physiological Principles; by Dr. WILHELM EBSTEIN, translated by Prof. H. H. KEANE, B.A. London: H. Grevel, 1884.—This little book has been so extensively reviewed in the lay press, that the medical profession may well be excused if it has come to entertain a certain prejudice against it. Such prejudice, if it exists, is undeserved. The work is written in a thoroughly scientific spirit, and has no sign of charlatanry about it. It was originally composed as an address to a meeting of physicians, and it is only in the parts dealing with the treatment of corpulence that the author has taken pains to adapt it to the capacity of non-medical readers. It is unfortunate that it has been made the subject of so many leading articles in the daily journals. Professor Ebstein's main contention is, that the moderate use of fat, by diminishing the decomposition of the albuminous elements of food, lessens the appetite, and so renders bearable the restriction of diet necessary in the treatment of corpulence. He therefore allows in moderation such articles as *pâté de foie gras*, salmon, bacon fat, fat roast pork and mutton, kidney fat, asparagus, spinach, and the various legumes; but he unconditionally forbids the consumption of sugar, sweets and potatoes, and limits the allowance of bread to from three to three-and-a-half ounces a day. That is the gist of Dr. Ebstein's teaching; but we would advise all who are scientifically interested in the question to read his book, which, however, we regret to say, has been translated without a sufficient knowledge of medical terminology.

ABSTRACTS AND EXTRACTS.

SURGERY.

ETHERISATION BY THE RECTUM.—The *New York Medical Journal* (May 24th) states that this practice has now been tried in many cases in that city, and with results which, while they prove that it possesses some excellent features, yet show the importance of caution being greater than was at first suspected. The chief benefit derivable from the practice is, the economising of ether employed for anæsthesia, and the avoiding of the preliminary strangling and struggling, so trying to both patient and surgeon. In almost all instances the patient has gradually and with reasonable promptitude fallen into a state resembling natural sleep, preceded by little, if any, exhilaration, and by none of the laryngeal irritation so common in inhalation of ether. The suppression of the nausea which supervenes on recovering from etherisation by inhalation does not seem quite so certain. The method, however, has its serious dangers; for even during the few weeks it has been on trial in New York, two deaths have occurred. One of these was that of a child, and the opinion begins to prevail that the method is not appropriate for children, as the distension and irritation of the intestine produced by the vapour may in them produce serious results. The other case was that of a woman,

whose general health was not known to be impaired (the anæsthesia being merely induced while cauterizing a chancroid); but after death the whole of the large intestine, and the lower part of the small one, were found in a state of acute ulceration. It seems that in the practice of some surgeons intestinal irritation has been met with in almost all the cases, while in others this has been quite the exception; and the inference is, that sufficient care has not always been taken not to inject liquid ether into the rectum; and it is recommended not to employ a tube sufficiently long to allow the vapour to condense before it enters the canal, and to clear the bowels out by an enema before the administration is undertaken.

Digital Compression in Femoral Aneurysm.—Dr. Nicolich, of Trieste, relates the case of a pilot, 44 years of age, who came under his care in 1879 for an aneurysmal tumour, the size of a goose's egg, situated between the middle and upper thirds of the inner portion of the thigh. This was completely cured by means of only nine hours' digital compression. Four years afterwards (December, 1883) the same man presented himself again (having in the meantime, until four months ago, been well able to perform his duties as a pilot), with an aneurysm of the femoral artery, on the same side, of the size of a large orange, and extending from the middle of the thigh to Poupart's ligament. Digital compression was again resorted to, and in a week the aneurysm had diminished in size by one-half, and was indurated and without pulsation. A fortnight later he was exhibited at the Medical Society, and his cure pronounced to be complete. The compression was almost entirely executed by the patient himself, and was suspended during the night and for some hours in the day, the limb then being kept in a state of forced flexion. During the progress of the case he was kept on a very rigorous diet, and took five grammes of iodide of potassium daily. — *Gazzetta Med. Lombardia*, April 26th.

Conservative Surgery.—In a recent number of the *New York Medical Record*, Dr. Meigs Case reports the result of a railway accident. A porter, aged 28, while handcoupling a locomotive, was caught by the heavy iron bar, which was driven through the left arm, fracturing both radius and ulna about 1½ inches in front of the elbow-joint. The radius was also fractured in its middle third, so that a four-inch piece of this bone, completely detached, lay transversly across the wound. Two other small pieces of loose comminuted bone were removed. The median nerve was torn half across; the ulnar artery and the soft parts adjacent were crushed, and the wound was filled with soot. The soft parts were crushed through near the radial attachment of the biceps, so that the forearm hung only by a band of skin less than two inches wide, and a very few unsevered fibres of the supinator longus and the extensor radialis longior, together with the brachio-radial artery, which was uninjured—so that there was a good pulse at the wrist. The patient "feared that the arm would drop off before he got home." Hopelessly crushed tissue was removed; the parts replaced and secured by interrupted sutures; and the arm—held in position by lateral splints of flannel and gypsum—was laid upon a pillow and covered with yeast poultices. At first there was considerable venous hæmorrhage, extensive swelling, and some sloughing of the bruised muscular tissue; but at the end of three months the patient had recovered, with some paralysis of the forearm and slight fibrous ankylosis of the elbow-joint; he is able to carry a pail of water, and handle a shovel or hoe as well as ever. Engravings from photographs, showing the condition of the limb at the time of the accident and after recovery, are appended to the original publication.

Removing Foreign Bodies from the Throat.—Dr. Veeder, of Lyons, New York, writes:—"A loop of ordinary suture wire, which may be readily bent to any shape desired, forms an available means of hooking such articles as pins and needles out of the throat, and has the merit of succeeding sometimes where more elaborate contrivances have failed."—*New York Medical Record*, March 1st.

REPORTS OF SOCIETIES.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Friday, May 16th, 1884.

Dr. T. O. Dudfield, President, in the Chair.

The Sanitary Supervision of Bakehouses.

Dr. Alfred Hill read a paper on "The Sanitary Supervision of Bakehouses, with especial reference to those of Birmingham." After dwelling on the advantages likely to accrue to the public health by the transfer of the duties of supervision from the Factory Inspector to the Medical Officer of Health, Dr. Hill proceeded to state his own experience of the working of the Bakehouses Amendment Act of 1883. In four months he had personally inspected 77 bakehouses, and his inspector 121, making 198. Even at this rate it would be at least twelve months before all had been visited even once, and the question arose how far the Medical Officer of Health might delegate his duties to others. He believed that he might and indeed he must, though retaining his responsibility. Accordingly in Birmingham they had appointed an inspector who was exclusively employed with bakehouses, cowsheds, and milk shops, the numbers of which were about 600, 300, and 2,000 respectively. Dr. Hill's practice was to confer once or twice a week with the inspector, examining his books and otherwise supervising his work. The points to which the attention of the inspector was particularly directed were cubic space ventilation and drainage, the proximity of sleeping apartments, w.c.'s, stables, &c., the general state of repair and cleanliness, and the employment of young persons in contravention of the law, Dr. Hill and the factory inspectors working in friendly co-operation, each frequently furnishing valuable information to the other. Very few of the bakehouses were underground, the great majority being either separate buildings or back kitchens converted into bakehouses. The cubic space averaged 827 feet per head, varying between 190 and 5,000. The drainage was generally good, faults, and these easily remedied, having been found in 12 only. Ventilation was deficient in 20, the opening being closed by the men in their fear of draughts. There were no closets or sleeping rooms in connection with the bakehouses and only once a stable in unpleasant proximity. Dogs were the only animals found in three cases, and a strong smell of mice in one instance. The general state of cleanliness was satisfactory, whitewashing being voluntarily performed every three months as a rule, although painting seemed often to have been neglected. In one case a child, and in others 36 young people and 21 women were found to be illegally employed. The inspector's visit had never been resented, suggestions had been gladly acted on; occasionally a formal notice had been served, but in no case had any legal proceedings been necessary.

The discussion which followed, and in which Drs. Dudfield, Bate, A. Carpenter, W. Simpson (Aberdeen), and Messrs. Murphy, Lovatt, and Cobner took part, turned mainly on the question whether premises where meat and fruit pies were baked came within the scope of the Act. In many places the condition of these premises was filthy in the extreme, and the floors were covered to a depth of an inch or more with a mixture of droppings of flour, bad butter, eggs, &c. In some districts the authorities assumed them to be bakehouses, and dealt with them as such; in others the owners paid no regard to the notices served on them, relying on the letter of the Act, which specified bakehouses for bread, biscuits, and confectionery only. In Aberdeen, Dr. Simpson said, a house condemned as unfit for human habitation had been reopened as a pie-house! And he had seen pastry made in a water-closet.

Dr. Carpenter thought that the notification of infectious diseases enforced in some districts in respect of milk shops, should be extended to baker's shops, as the handling of bread by persons in attendance on small-pox, &c., or convalescent from scarlatina, must be highly dangerous.

Dr. Hill, in reply, said that in Birmingham they had not met with any opposition from the owners of pie-shops, which they considered to be bakehouses, there being a baker's oven; and as to infectious diseases, though they had no by-laws for their compulsory notification, their practice in cases where the parties refused either to close the shops or to send the patients to the hospital, was to station a policeman at the door to inform all customers of the presence and nature of the disease. The most democratic governments are the most arbitrary, and they were accustomed in Birmingham to act regardless of the strict legality of a procedure.

A new Calculating Slide Rule.

Dr. Bate then exhibited an improved form of calculating slide rule, which he had found very useful in statistical work, and read a paper on its use, which will be found in full in another column. It was the invention of Mr. Geo. Fuller, M.I.C.E., and was made by W. F. Stanley, of the Great Turnstile, Holborn. By the combination of a solid cylinder with a hollow one sliding on it telescopically, and three indices, though not 3½ feet long it is equivalent to a straight slide rule of 83 feet long, or a circular rule 13 feet in diameter. In using it all measures must be reduced to decimals, which it works with accuracy to the 4th place.

A visitor observed that Professor Galbraith, of Trinity College, Dublin, had recommended the use of the sliding scale to the students there, giving the preference to a form designed by Major-General Hannyngton, and made by Messrs. Aston and Mander, 25, Old Compton Street, Soho.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE VII.

Food.

Cocoa and Chocolate.

It is scarcely necessary to remind the medical reader that cocoa is the produce of the Theobroma cacao; a shrub growing wild in Mexico, but which has been cultivated with great success in the West Indies generally. The egg-shaped beans are embedded in a red marrow-like substance, and enclosed in a common capsule. The fruit of the cultivated varieties ripens twice a year and is gathered by coolies. A coolie picks about two bushels daily. The pods are first cut from the tree, a small piece of the stalk being left; the coolie then takes a pod in each hand, knocks them together, which splits each in halves, and then with one draw of his fingers strips all the beans off the centre pulp. The pods are thrown at the foot of the tree and act as a manure. The beans, which at this stage abound in mucilage, are then allowed to ferment. This process is technically called "sweating" and takes from five to nine days; the object of the sweating is to get rid of the mucilage by a sort of putrefaction. At the end of the time the mass looks very disgusting and might be described as a heap of rottenness; but on washing, the beans come out beautifully bright and clean, and have lost a very disagreeable flavour, and the power of germinating. They are now dried, and if all has been successful, the beans have a fine, mild flavour, a cinnamon colour, and a "free" break.

The cocoas shown in the Exhibition, omitting the unground nibs, are "cocoa extracts," "cocoa powders," chocolate, and cocoa mixed with various substances. Cocoa either considered as cocoa, or when mixed with sugar and converted into chocolate, is both a food and a drink. Its high percentage of nitrogenous matters and its very considerable amount of fat, separate it sharply from tea and coffee which it only resembles in containing a crystalline principle "Theobromin," concerning which latter we may in passing remark that recent chemical views have degraded both Theine and Theobromin from the alkaloid class, and shown their strong relationship to uric acid, so that it is more doubtful than ever whether the stimulating effects of tea and coffee have anything to do with the crystalline semi-alkaloid they contain. That cocoa or chocolate has any special exciting properties is open to enquiry, but that the cocoa fat, from its complex composition, may have very important nutritious properties is probable.

Messrs. F. Allen and Sons have an extremely attractive exhibit in the Western Gallery, showing the actual manufacture of confectionery, &c. We have received various samples of their chocolate and cocoa. The chocolate is of good flavour and yielded to analysis 21 per cent. of cocoa fat and ·6 per cent. of Theobromin, which would correspond to about 41 per cent. of real cocoa. The cakes are hard, with a full fracture, and would probably keep for any reasonable time. The chocolate creams were also found of good quality and made of pure materials.

A sample of their homœopathic cocoa is stated to be compounded of cocoa, East Indian arrowroot and cane sugar, and a microscopical and chemical examination confirms this statement.

The well known firm of Messrs. Fry and Sons exhibit chocolate in cakes, cocoa extract and homœopathic cocoa, as well as chocolate creams. The cake chocolate is a very excellent sample of well made chocolate; the cocoa extract, as stated on the label, is the cocoa only partially deprived of its fat; and this we find to be correct. We think that Messrs. Fry have been specially successful in their chocolate confectionery; the latter used to be rather a French speciality, but our English manufacturers are now producing samples quite equal to any French brand.

Messrs. Bensdorp and Co.'s Dutch Cocoa Powder is also extremely good. In short, the different cocoas and chocolates of the firms named above differ only in such minute details of flavour, that it will be a somewhat difficult matter for the jury to say which is superior to the rest.

The Baron Liebig Company show various pleasant tasting cocoas and chocolates; to one of their cocoas they have added "Legumine," with the object, it is presumed, of making it a nutritious food. This cocoa we found to contain 3 per cent. of nitrogen which, if translated into albuminoids, would be equal to about 19 per cent.

Messrs. T. and H. Smith and Co. exhibit some cocoa and milk and chocolate and milk in hermetically sealed tins. The flavour of these tinned products was good; the pastes were neutral in reaction, and contained no trace of metallic contamination.

The Kola Nut.

It is germane to the present article to notice here some of the new food products exhibited by Messrs. T. Christy and Co., 155, Fenchurch Street, in the South Gallery.

The Gourou or Ombené seed, more commonly known as the Kola nut, is of a chocolate brown colour and about the size of a Brazil nut. It is the produce of the *cola acuminata* and is a native of tropical Africa. There is no article of produce which occupies so exalted a social and dietetic position with negro tribes; it is among them a charm, a medicine and a food; it is the propitiatory offering to the living and the dead, to strangers and to gods.

Now that there are indications of future trade with Central Africa, and the Kola nut is procurable, it may become of very considerable importance, for its chemistry, so far as known, shows that the Kola nut stands between cocoa and coffee, and its infusion makes an agreeable and stimulating drink. Samples of Kola nut submitted to us by Messrs. Christy give the following general results. A yellow resin extracted by petroleum ether amounted to ·6 per cent. The alcoholic extract contains 14·42 per cent. glucose, Theobromin, Theine, and an astringent principle. The ash is 2·9 per cent. The amount of Theine was found to be 1·55 per cent. The Kola nut is reputed to be useful in diarrhœa, and to have the properties of allaying hunger and producing endurance of fatigue.

Samples of Liberian coffee, of maté and of the cuca or coca, with several other novel foods and remedies are also exhibited by the same firm.

"Sterilised Soups."

Messrs. Moir and Sons displayed on Saturday samples of their preserved foods in the jury room at the Technical Institute. A tin of mutton which had been out to the Crimea and back and was over 30 years old, was opened, and found to be perfectly sweet and good.

Messrs. Moir have been for some time past preserving soups, fruits and vegetables in upright clear glass jars. The mouths are closed by corks and secured by hermetically sealed metallic caps. In this process, the preserved substances incur no risk of contamination by metals, and any putrefactive change is at once evident. Since all animal broths are feebly acid and most fruits strongly acid, such a method of preservation is infinitely superior to that of preservation in tins, and from a health standpoint is unexceptionable. Looking over Messrs. Moir's attractive exhibit, the scientist is involuntarily reminded that the clear organic liquids of all kinds, arranged in the case, are so many sterilisations, and popularly exemplify the truth of one of the most important modern theories.

THE LABORATORY OF M. PASTEUR, &c.

On Saturday, Jury No. 5 paid a visit to the West Central Galleries and closely examined the apparatus exhibited by M. Pasteur. M. Roux explained to the Jury in great detail the methods of sterilisation adopted, and showed various cultivation flasks. In this exhibit there are tubes of the attenuated anthrax virus, which it will be remembered Dr. Klein (12th Report of Medical Officer to the Local Government Board, Supplement) examined with far from satisfactory results. There is also a very good improved form of hypodermic syringe, made especially for the inoculation of cattle. M. Roux stated that 4,000 cattle have, by means of similar syringes, been inoculated in a day. The sterilising tubes, flasks, and incubators exhibited are not novel, and are well-known to all engaged in biological research.

The Municipal Laboratory of Paris have a stand made attractive with glass and bright metal. It may impress all, save those who are intimately acquainted with the instruments and methods used by the English food analysts; by the latter the exhibit will be pronounced rather behind than in advance of the times.

Mellin's Food.—Mr. Mellin writes to call our attention to the fact that explicit directions are given with each bottle that the food should be only used *with* milk. Our remarks on this head last week were, we regret, open to misconstruction.

GENERAL CORRESPONDENCE.

HYDRO- AND PYO-SALPINX.

[To the Editor of the Medical Times.]

Sir,—The statements that some of my patients have been under treatment in Guy's Hospital were made by the patients themselves. As a matter of accident, I have had no occasion to enquire into the accuracy of the statements concerning Guy's; but as I have done so about similar statements concerning many other hospitals and have found them substantially accurate, I have had no reason to doubt those affecting Guy's. But it is wholly immaterial whether they are accurate or not. The important question is this—is it likely that diseases so common elsewhere are quite or almost non-existent at Guy's? An affirmative answer involves such a contradiction of the doctrine of chances, that I for one cannot accept it. I prefer to believe that they exist at Guy's, as I said, to the extent of perhaps a score of cases at the present time, most of them probably wearing the ineffectual and detrimental pessary.

The question asked by Dr. Horrocks about the possibilities of the diagnosis in these cases, I have already answered, as well as I know how to do it, in more than one of my papers on the subject, and therefore I need not return to it here.

I propose to take one or two other points raised by this discussion, if you will kindly allow me space in your columns, within the next few weeks.

I am, &c.,

Birmingham, June 23. LAWSON TAIT.

THE COLLEGE OF PHYSICIANS AND ITS FELLOWSHIP.

[To the Editor of the Medical Times.]

Sir,—One of your correspondents recently expressed a hope that some of the members of the College of Physicians admitted in 1860, might be elected to the fellowship. Probably, a better suggestion would be that members of 25 years' standing might be allowed to submit their names to a general meeting of the fellows for election. Thus, the present year would comprise the group of members admitted to the College by examination prior to 1859, while next year would include the much larger body of members admitted without examination in 1860. Afterwards, the same privilege to extend to all members who shall survive 25 years of membership, although they may previously have been rejected for nomination by the Council. Such arrangement need in no way affect the present early nomination of the fittest by the Council, but would secure a fair prospect to most, so inclined, of ultimately being included in the honourable fellowship of the College.

I am, Sir, yours, &c.

A MEMBER.

London, June, 1884.

MEDICAL NEWS.

University of Dublin. (*School of Physic in Ireland*).—At the Trinity Term Examination for the Degree of Bachelor of Medicine (M.B.), held on Monday, June 9, and following days, the successful candidates passed in order of merit as follows:—

Henry T. Bewley, Louis J. Werner, John S. Fenton, Samuel Hickson, William M. Hewson, Telford Smith, Daniel R. O'Sullivan, and Henry Shackleton, equal, William T. Swan, Thomas Parr, Henry A. Ellis, Baptist G. Frith, William Grandy, Nicholas C. Ferguson, George Scarr, George W. Powell, William Lacy-Hickey, Joseph V. Manning.

At the Trinity Term Examination for the Degree of Bachelor in Surgery (B.Ch.), held on Monday, June 16, and following days, the successful candidates were placed in order of merit as follows:—

Louis Werner, Henry T. Bewley, John S. Fenton, Samuel Hickson, and Thomas Parr, equal, William M. Hewson, William T. Swan, Reginald J. Windle, Nicholas C. Ferguson, and Robert Morrow, equal, George William Powell, Hugh N. Kenny.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 19th, 1884:—

Reginald Bean Anderson, St. Mark's Road, Notting Hill, W.; Reginald Treacher Bowden, Tenbury, Worcestershire; Frederick Bryan, Chantry Road, Brixton; Jno. Woodward Crowther, The Villas, Silverdale; Henry Fooks, 3, Kempsford Road, S. E.; Jno. Hughes-Jones, 102, Petherton Road, N.; George Henry Weston, Sidlaw Terrace, Bognor.

The following gentlemen also on the same day passed their primary professional examination:—

Henry R. Evans, St. Thomas' Hospital; Arthur William Veness, Westminster Hospital.

The Princess of Wales has fixed July 14th for the ceremony of opening Miss Mary Wardell's Convalescent Home for scarlet fever, at Brockley Hill, Stanmore.

The Deputy-Coronership of Westminster.—Mr. Langham has resigned this office which he has held since 1849, but it is understood that, should the duties of his new office permit, he will continue to act as deputy for Westminster, pending the election of his successor.

University of Oxford.—The degree of B.M. has been conferred upon the following:—William Augustine Ellison, and Bertram Hunt, University; Reginald John Ryle, Trinity; Frederick Augustus Dixey, Wadham; Oliver Scattergood, and Arthur Molineux Jackson, Queen's; and Robert Holman Peck, Exeter.

Animal Vaccination.—Owing to the enormous number of applicants for vaccination and re-vaccination, the Government department, presided over by Dr. Cory, have opened a

branch establishment at 85, Southampton Row, W.C., for men only; the head establishment at Lamb's Conduit Street being reserved for women and children.

Alleged Death from Overwork at School.—A coroner's inquest was held at Dudley, on Tuesday, respecting the death of a little girl who attended a Board School. She complained on Saturday last of headache caused by her lessons, became alarmingly ill next day, and died before a doctor could be sent for. The jury returned a verdict of death from natural causes, accelerated by overwork at school.

Outbreak of Enteric Fever.—An alarming outbreak of typhoid fever is reported to have occurred at Mr. Muller's Orphan Asylum, Ashley Down, near Bristol, where there are fully 2,000 children, 70 cases and four deaths having already occurred. This is the third outbreak within recent years, and the managers have been advised to discard the present water supply from the wells, but as chemical analysis has not condemned them, they have hitherto declined to do so. The managers have been urged to call in a sanitary engineer for a thorough examination of the buildings.

Messrs. W. Hill and Sons, of Bishopsgate Street, formally opened on Saturday a model bakery at Alexander Street, in the presence of several medical officers of health and hygienists. The bakehouses are well-lighted and ventilated, contamination by sewer air is impossible, and the bread is entirely made by machinery. After luncheon, Dr. Tripe, Dr. Lovett, Mr. Wynter Blyth and Mr. Lakeman, Inspector of Factories, made some remarks on the general subject, and recommended the encouragement of large bakeries, in which the proper and expensive plant for the cleanly preparation of bread could alone be installed.

Naval Medical Department.—The following appointments have been made:—Deputy Inspector-General Belgrave Ninnis, M.D., to the Chatham Division of Royal Marines; Staff Surgeon J. Wood, to the *Swift*. Surgeons—J. Acheson, M.D., to the *Jackal*; R. E. Biddulph, to the *Vigilant*; William M. Craig, M.B., to the *Alecto*; George J. Fogerty, to the *Banterer*; John L. Barrington, to the *Ready*; William Tait, M.B., to the *Cambridge*; John O'Callaghan, George Bate, Joseph H. Whelan, M.D., to the *Alexandra*, additional; Michael J. McCarthy, M.D., to Plymouth Hospital; Henry F. Iliewicz, to the *Ganges*.

Vaccination and Small-pox.—The National Health Society (44, Berners Street, W.) having invited the criticism of the Local Government Board upon the little pamphlet entitled: Facts concerning Vaccination for Heads of Families, which the Society has prepared for house to house distribution through the agency of the district vaccination officers, an official letter, dated 19th instant, has been sent from that department stating that the Board have been glad to comply with the request of the National Health Society, and making certain suggestions for the improvement of the pamphlet. The Board have already sanctioned in a number of instances the repayment of the expenses for distribution of the pamphlet out of the Metropolitan Common Poor Fund, and it may now therefore be fairly regarded as an official publication on the subject of which it treats.

Small-Pox in London.—A circular has been issued to boards of guardians from the Local Government Board urging that in many districts it will be advisable to appoint a staff of assistant vaccination officers to make a house-to-house visitation, with the view of securing the vaccination of unvaccinated children, and of inducing persons who have not been already re-vaccinated to become so. It is further suggested that a statement of the advantages of vaccination and re-vaccination should be left at each house, while means should be taken to obtain information of every fresh case of small-pox. In addition to the usual weekly attendances at the vaccination stations, special evening attendances should be appointed, to suit the convenience of artisans and others who cannot conveniently resort thither in ordinary working hours. Attendances oftener than once a week may sometimes usefully be appointed to take place at the stations, and even attendances on every day at a fixed hour for the vaccination of persons known to have been exposed to exceptional risks of small-pox. In particular cases where small-pox actually exists in a house—especially in a sub-let or tenement house—it will be desirable for the public vaccinator, or his appointed deputy, immediately on receiving information of the outbreak to proceed to the infected house and there perform any needed vaccination or re-vaccination.

Anderson's College, Glasgow.—The annual meeting of the trustees of Anderson's College, Glasgow, was held yesterday afternoon, when Dr. Andrew Fergus, the president, occupied the chair. It was stated in the report, which was adopted, that the other bodies embraced with the College in the scheme prepared under "The Educational Endowments Act" had approved of a proposed grant of 5,000*l.* to the Medical Faculty on its separation from the institution. The number of students attending the College during the past Session was given at between 2,000 and 3,000. It was unanimously agreed to elect as trustees Messrs. W. M'Call, J. C. M'Ewen, and T. B. Mathieson. The election of Dr. James Christie as Professor of Physiology was sanctioned, and the occupants of the other chairs were re-appointed. It was provided, however, that, in the event of the scheme mentioned becoming law, the Medical Faculty should be bound to remove from the College when required to do so. The other business was of a formal character.

The Synthesis of Xanthine.—M. Armand Gautier, who is expected to succeed Professor Wurtz at the Faculté de Mèdecine, and who has been so long engaged in researches on xanthine, uric acid, and sarcine bodies, so intimately related and convertible within the economy, has just announced to the Académie de Mèdecine (*Bulletin*, June 17), that he has succeeded in producing xanthine by synthesis. Hitherto, the repeated efforts which have been made to effect a synthesis of any one of these three substances have been fruitless. Xanthine is one of the bodies which result normally in living beings from the oxidation of albuminoid bodies, differing by one atom less of oxygen from uric acid, and by one atom more of oxygen from sarcine. This production of xanthine beyond the forces of the living economy is the first decisive step in the synthesis of albuminoid matters. M. Gautier accomplished this by heating hydrocyanic acid mixed with water, and acetic acid to a temperature of from 140° to 150° C.

The Sanitary State of Calcutta.—The Calcutta correspondent of the *Times* telegraphs that the action, or rather inaction, of the Calcutta Corporation with respect to the sanitation of the town is attracting much attention. The Surgeon-General of Bengal, in a correspondence lately published, expressed the opinion, first, that the steps recently taken for sanitary improvement were inadequate; secondly, that the cholera and smallpox mortality during last March and April was abnormal and alarming, and that there was likely to be a recurrence of the same state of things next year; thirdly, that the Municipal Commissioners as a body were not qualified to judge what special sanitary measures were most required, or to realize the responsibility under which they lay as regarded the condition of the unhealthy portions of the city; and fourthly, that the only hope of real improvement would consist in the appointment of a select body of experts, outside the Corporation, who would be capable of forming an opinion, at once scientific and independent, on the requirements of the case, and on the best practical manner of meeting them, and whose recommendations might be immediately carried out by order of the Government. The municipal council admit, we believe, that the state of things needs remedying, but they are at present without a health officer to advise them, and meanwhile everything is at a standstill. The appointment has been advertised, and we hope that a competent officer, skilled in sanitary work at home, will be appointed, who will be able, by the force of his character and the weight of his opinion, to induce the Commissioners to take all the needful steps.

A Doubtful Practice.—"It appears to be the custom among certain instrument-makers in this, and, we presume, other cities, to give the physician who sends them a patient to be fitted, a certain per cent. on the profits."—*New York Medical Record*, May 31st.

COUNTERFEIT SARDINES IN COURT.—The tricks of trade are frequently divulged in court when the partners in the deception fall out with each other. It appears that in the United States sardines command about 50 per cent. higher price than the fish caught in American waters. There is, therefore, a great temptation to pack the latter in boxes with French labels. A contract was made by a firm in New York for a large lot of "domestic" sardines with "fancy" labels, that is, labels stating that the sardines were packed and caught and packed in France. For some reason the sardines were not accepted when tendered and a suit was brought for their value. In defence, it was alleged that the contract was void, being against public morals, and could not be upheld. This was the view taken by the Court, which held that the practice was a dishonest imposition upon consumers who were without knowledge of the deception. It was said by the judge, "Consumers may not be wronged by eating American sardines while they think they are eating French. One may be as wholesome and savoury as the other, but undoubtedly the labels are not used to instil this information into the minds of eaters. They are used to get a higher price that would be given if the label told the fact as to the origin of the fish."—*New York Medical Record*, May 24.

STRATFORD-UPON-AVON.—On Saturday, June 21st, the new hospital in the Alcester Road was opened. It is a handsome red brick building, consisting of a central administrative block, and east and west wings for the male and female patients respectively. There are five wards in each wing, all on the same floor, viz.: at the end of the corridor a large ward for six beds, there are two other wards for three beds a-piece, a separate ward for three beds, and one convalescent ward. Thus each wing is to accommodate fifteen patients. The average height of the wards is 14 feet, and 1,260 cubic feet of space is the allowance per patient. The sanitary arrangements of the hospital would appear to be in every way satisfactory. The furniture and fittings are very complete, and the whole building reflects the greatest credit on the donors Mr. and Miss Gibbins.

APPOINTMENTS.

BALFE, J., L.R.C.P.—Medical Officer to the Norwich Friendly Societies' Medical Institute.

BECKETT, FRANCIS MEARS, M.R.C.S. Eng., and L.S.A.—Medical Officer to the Workhouse Ely Union, *vice* Mr. G. M. Sinclair, deceased.

BUTLER, WILLIAM JOHN, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A.—Medical Officer to the Castle Donington District, Shardlow Union, *vice* Mr. J. W. G. Sellow, resigned.

CARSON, J. S., M.B.—Medical Officer to the Norwich Friendly Societies' Medical Institute.

CASE, PERKINS WILLIAM PERKINS, M.D. and M.C. Edin.—Medical Officer to the Fourth District, Croydon Union, *vice* Dr. Barnes, resigned.

CAVE, E. J., M.R.C.S.—Resident Medical Officer to the Royal United Hospital, Bath, *vice* M. W. H. Russell, M.R.C.S., resigned.

CHANCE, ARTHUR J., L.R.C.S.I.—Surgeon to the Jervis Street Hospital, *vice* J. S. Hughes, deceased.

CLARK, W. R., M.B.—Assistant Medical Officer to the Eastern Hospital.

COOPER, H. C. E., M.R.C.S.—Resident Medical Officer to the Hospital for Diseases of the Throat, Golden Square.

DEY, ALEXANDER, M.B. and M.C., Aberdeen.—Medical Officer to the Chatton District, Glendale Union.

GREENSILL, J. H., M.R.C.S.—Resident Medical Officer to the Guest Hospital, Dudley, *vice* C. J. Muriel, M.R.C.S., resigned.

HAWTHORN, FREDERICK, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A. Lond.—Medical Officer to the Leigh District, Uttoxeter Union, *vice* Mr. H. O. Hawthorn, deceased.

HYNE, F. A.—Honorary Medical Officer to the Jersey General Dispensary.

JONES, WILLIAM REES, M.B. and C.M. Glas.—Medical Officer to Defynock District, Brecknock Union, in succession to W. Clay Jones, deceased.

MACLAREN, JAMES ALEXANDER, M.B. and M.C.—Medical Officer to the Stickney District, Spilsby Union, *vice* Dr. Greinoldsby, resigned.

MAITLAND, A. D., M.R.C.S.—Senior House Surgeon to the Sunderland Infirmary, *vice* E. F. Flynn, L.K.Q.C.P.I., resigned.

MALTBY, A., M.R.C.S.—Assistant House Surgeon to the Royal South Hants Infirmary, *vice* — Roberts, L.S.A., resigned.

MCDERMOTT, WILLIAM, M.D.Q. Univ. Ire., M.R.C.S. Edin.—Medical Officer to the Sixth District, Sudbury Union, *vice* Mr. C. W. Whistler, resigned.

MILLER, A. H., L.R.C.P.—Medical Officer to the Norwich Friendly Societies' Medical Institute.

MILLIGAN, R. A., M.R.C.S.—Surgeon to the General Infirmary, Northampton, *vice* G. F. Kirby Smith, F.R.C.S., deceased.

MOORE, JOSEPH, M.R.C.S.E., L.S.A., L.R.C.P. Edin. and L.M.—Medical Officer to the Middlewich District, *vice* James Hughes, deceased.

PEARSON, ALFRED WILLIAM, L.R.C.S. and L.R.C.P. Edin.—Medical Officer to the Kingswinford No. 3 District, Stourbridge Union, *vice* Mr. John Parrish, deceased.

PHILLIPS, F. W. B., B.A., B.Sc. Lond.—Assistant Medical Officer to the Eastern Hospital.

SUTTON, JOHN RICHARD HENRY, L.R.C.S.I., L.K.Q.C.P.I. & L.M.—Medical Officer to the Fourth District, Aylesbury Union, *vice* Charles Spencer, resigned.

WATSON, HENRY, M.D. and M.C. Aberdeen.—Medical Officer to the Fifth District, Norwich Union, *vice* Mr. T. T. Breese, resigned.

YOUNG, ADAM, L.R.C.S., Eng., L.R.C.P. and L.M., Lond.—Medical Officer to the Workhouse, *vice* Mr. R. M. Rathill, resigned.

VACANCIES.

BASFORD UNION.—Medical Officer to the Wilford District, in succession to Dr. John Hall, deceased. Area, 11,376 acres. Population, 5,059. Salary, £35 per annum.

COUNTY AND COUNTY OF THE BOROUGH OF CARMARTHEN INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, fire and light. Candidates must be registered to practice both in medicine and surgery, unmarried, and free from the care of a family. They must have a knowledge of the Welsh language, and will be required to enter into an agreement not to practice in the County of the Borough of Carmarthen for a period of five years. Applications, with testimonials, as to ability and character, to be sent to Mr. H. Howells, 11, Morley Street, Carmarthen, on or before July 12th.

DAVENTRY UNION.—Medical Officer to Third District, in succession to Mr. F. B. Swann, resigned. Area, 10,308 acres. Population, 3,808. Salary, £55 per annum.

DUDLEY DISPENSARY.—Resident Medical Officer. Salary, £130 with residence. Candidates must be Fellows or Members of the Royal College of Surgeons, England, Edinburgh, or Dublin, and hold a Medical and Surgical Diploma, and be registered. Applications with testimonials to be sent to Henry C. Brettell, Hon. Secretary, before July 1st. The election will take place on July 9th.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, SHADWELL, E.—Assistant Physician. (*For particulars see Advertisement.*)

GAINSBOROUGH UNION.—Medical Officer to the Haxey District, in succession to Mr. Thomas Stones, resigned. Area, 8,113 acres. Population, 1,982. Salary, £26 per annum.

KENSINGTON DISPENSARY.—Resident Medical Officer. (*For particulars see Advertisement.*)

QUEEN'S COLLEGE, BIRMINGHAM.—Professorship of Anatomy. Salary £262 10s. per annum. Applications with testimonials, to be sent to the Secretary, Joseph Lewis, 21, Paradise Street, Birmingham (from whom further particulars can be obtained), on or before June 30th.

SOCIETY OF APOTHECARIES OF LONDON.—Examiner in Medicine. (*For particulars see Advertisement.*)

WEST LONDON HOSPITAL, HAMMERSMITH, W.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London, and not practising as apothecaries. They are requested to attend a meeting of the Medical Council on July 1st, at 3.30 o'clock p.m. The election will take place on July 7th. Applications and copies of testimonials to be sent to the Secretary not later than June 30th.

DEATHS.

BISHOP, THOMAS, M.D., F.R.C.P., at 16, Rue Pierre Charron, Paris, on June 23rd.

RENTON, J. C. F., L.S.A., of 2, Roslyn Terrace, Hampstead, at Highbury, on June 23rd, in his 68th year.

THOMPSON, THOS., L.R.C.P., &c., of Sedgefield, Durham, on June 15th, aged 29.

WOOLDRIDGE, WILLIAM, M.R.C.S., L.S.A., at Laine House, Withdean, Brighton, on June 24th, in his 81st year.

NOTES, QUERIES, AND REPLIES.

A PHYSIOLOGICAL QUESTION.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Can you refer 'Enquirer' to *any authority* who can explain or give an answer to the following question:—"Do touch proper, Temperature and Pain, seem to you different modes of one skin-sensibility, or different kinds of sensibility (like Taste and Smell?) *Give reasons.*"

ENQUIRER.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In addition to the three instructions recommended by the Committee of the Ophthalmological Society of the United Kingdom appointed to enquire into the cause or prevention of blindness from ophthalmia neonatorum, published in your issue of the 14th instant, may I suggest a fourth instruction and that is: *Directly* a child is born to wipe its eyes with a soft cloth, particularly each inner canthus or corner, using in the act of wiping gentle pressure rather than friction. It may be added to or commence the first instruction.

I am, Sir, yours &c.

Sussex, June 24th, 1884. WILLIAM ELLIOTT PORTER.

COMMUNICATIONS RECEIVED—

Prof. Gairdner, Glasgow; Dr. Willoughby, London; Dr. Stephen Mackenzie, London; Dr. O. Sturges, London; Dr. Wolfe, Glasgow; Our Belfast Correspondent; Mr. Chatto, London; Mr. Wynter Blyth, London; The Secretary of the Apothecaries' Society, London; Dr. Champneys, London; Dr. Shelly, Hertford; The Secretary of the Medico-Psychological Association, London; Mr. Lawson Tait, Birmingham; The Chairman of the Improved Industrial Dwellings Company, London; Mr. John Bakers, London; Mr. G.
